Material from Chapter 3 of H&P (for DLX).

Material from Chapter 6 of P&H (for MIPS).

Outline: (In this set.)

Unpipelined DLX Implementation. (Diagram only.)

Pipelined DLX and MIPS Implementations: Hardware, notation, hazards.

Dependency Definitions.

Data Hazards: Definitions, stalling, bypassing.

Control Hazards: Squashing, one-cycle implementation.

Outline: (Covered in class but not yet in set.)

Operation of nonpipelined implementation, elegance and power of pipelined implementation. (See text.)

Computation of CPI for program executing a loop.

FIGURE 3.1 The implementation of the DLX datapath allows every instruction to be executed in four or five clock cycles.

Note: diagram omits connections for some instructions.

## Pipeline Segments a.k.a. Pipeline Stages

Divide pipeline into segments.

Each segment occupied by at most one instruction.

At any time, different segments can be occupied by different instructions.

Segments given names: IF, ID, EX, MEM, WB

Sometimes MEM shortened to ME.

## Pipeline Registers a.k.a. Pipeline Latches

Registers separating pipeline segments.

Written at end of each cycle.

To emphasize role, drawn as part of dividing bars.

Registers named using pair of segment names and register name.

For example, IF/ID.IR, ID/EX.IR, ID/EX.A (used in text, notes).

if\_id\_ir, id\_ex\_ir, id\_ex\_rs\_val (used in Verilog code).

## Pipeline Execution Diagram

Diagram showing the pipeline segments that instructions occupy as they execute.

Time on horizontal axis, instructions on vertical axis.

Diagram shows where instruction is at a particular time.

```
6
Cycle
                            2
                                 3
                        1
add r1, r2, r3
                   _{
m IF}
                       ID
                            ΕX
                                 MEM WB
and r4, r5, r6
                        IF
                            ID
                                 EX
                                     MEM WB
lw r7, 8(r9)
                            IF
                                 ID
                                     EX
                                          MEM WB
```

A vertical slice (e.g., at cycle 3) shows processor activity at that time.

In such a slice a segment should appear at most once ...

- ... if it appears more than once execution not correct ...
- ... since a segment can only execute one instruction at a time.

# Pipeline Control

06-7

```
Setting control inputs to devices including ...
... multiplexor inputs ...
... function for ALU ...
... operation for memory ...
... whether to clock each register ...
... et cetera.
```

Options for controlling pipeline:

• Decode in ID

Determine settings in ID, pass settings along in pipeline latches.

• Decode in Each Stage

Pass opcode portions of instruction along.

Decoding performed as needed.

Real systems decode in ID.

For clarity, diagrams misleadingly imply decoding in stage needed ... ... by passing entire instruction along.

Example given later in this set.

#### Remember

```
Operands read from registers in ID...
... and results written to registers in WB.
```

## Consider the following **incorrect execution**:

```
7
! Cycle
                                    5
                                        6
add r1, r2, r3 IF ID
                           MEM WB
                        EX
sub r4, r1, r5
                    IF
                        ID
                            EX
                                MEM WB
and r6, r1, r8
                                EX
                                    MEM WB
                            ID
xor r9, r4, r11
                            IF
                                    EX
                                        MEM WB
                                ID
```

Execution incorrect because ...

```
... sub reads r1 before add writes (or even finishes computing) r1, ...
... and reads r1 before add writes r1, and ...
... xor reads r4 before sub writes r4.
```

```
Incorrect execution due to...
... dependencies in program...
... and hazards in hardware (pipeline).
Incorrect execution above is the "fault" of the hardware...
... because the ISA does not forbid dependencies.
```

## Dependency:

A relationship between two instructions ...

... indicating that their execution should be (or appear to be) in program order.

#### Hazard:

A potential execution problem in an implementation due to overlapping instruction execution.

There are several kinds of dependencies and hazards.

For each kind of dependence there is a corresponding kind of hazard.

## Dependency:

A relationship between two instructions ...

... indicating that their execution should be, or appear to be, in program order.

If B is dependent on A then B should appear to execute after A.

## Dependency Types:

- True, Data, or Flow Dependence (Three different terms used for the same concept.)
- Name Dependence
- Control Dependence

```
Data Dependence: (a.k.a., True and Flow Dependence)
```

A dependence between two instructions ...

... indicating data needed by the second is produced by the first.

## Example:

```
add r1, r2, r3
sub r4, r1, r5
and r6, r4, r7
```

The **sub** is dependent on **add** (via **r1**).

The and is dependent on sub (via r4).

The and is dependent add (via sub).

Execution may be incorrect if ...

- ... a program having a data dependence ...
- ... is run on a processor having an uncorrected RAW hazard.

There are two kinds: antidependence and output dependence.

## Antidependence:

A dependence between two instructions ...

... indicating a value written by the second ...

... that the first instruction reads.

### Antidependence Example

```
add r1, r2, r3 sub r2, r4, r5
```

sub is antidependent on the add.

Execution may be incorrect if ...

... a program having an antidependence ...

... is run on a processor having an uncorrected WAR hazard.

# Output Dependence:

A dependence between two instructions ...

... indicating that both instructions write the same location ...

... (register or memory address).

### Output Dependence Example

```
add r1, r2, r3 sub r1, r4, r5
```

The sub is output dependent on add.

Execution may be incorrect if ...

- ... a program having an output dependence ...
- ... is run on a processor having an uncorrected WAW hazard.

## Control Dependence:

A dependence between a branch instruction and a second instruction ...

... indicating that whether the second instruction executes ...

... depends on the outcome of the branch.

```
beq $1, $0 SKIP # Delayed branch
nop
add $2, $3, $4
SKIP:
sub $5, $6, $7
```

The add is control dependent on the beq.

The sub is not control dependent on the beq.

#### Hazard:

A potential execution problem in an implementation due to overlapping instruction execution.

#### Interlock:

Hardware that avoids hazards by stalling certain instructions when necessary.

## Hazard Types:

#### Structural Hazard:

Needed resource currently busy.

#### Data Hazard:

Needed value not yet available or overwritten.

#### Control Hazard:

Needed instruction not yet available or wrong instruction executing.

Identified by acronym indicating correct operation.

- *RAW*: Read after write, akin to data dependency.
- WAR: Write after read, akin to anti dependency.
- WAW: Write after write, akin to output dependency.

DLX and MIPS implementations above only subject to RAW hazards.

RAR not a hazard since read order irrelevant (without an intervening write).

When threatened by a hazard:

• Stall (Pause a part of the pipeline.)
Stalling avoids overlap that would cause error.

This does slow things down.

• Add hardware to avoid the hazards.

Details of hardware depend on hazard and pipeline.

Several will be covered.

Cause: two instructions simultaneously need one resource.

Solutions:

Stall.

Duplicate resource.

Pipelines in this section do not have structural hazards.

Covered in more detail with floating-point instructions.

HP Chapter-3 DLX and MIPS Subject to RAW Hazards.

Consider the following **incorrect execution** of code containing data dependencies.

```
! Cycle
                             3
                                     5
                                         6
                                             7
add r1, r2, r3 IF ID
                         EX
                             MEM WB
sub r4, r1, r5
                     IF
                         ID
                             EX
                                 MEM WB
and r6, r1, r8
                         IF
                             ID
                                 EX
                                     MEM WB
xor r9, r4, r11
                             IF
                                     EX
                                 ID
                                         MEM WB
```

Execution incorrect because ...

```
... sub reads r1 before add writes (or even finishes computing) r1, ...
```

... and reads r1 before add writes r1, and ...

```
... xor reads r4 before sub writes r4.
```

Problem fixed by *stalling* the pipeline.

#### Stall:

To pause execution in a pipeline from IF up to a certain stage.

With stalls, code can execute correctly:

For code on previous slide, stall until data in register.

```
8
! Cycle
                                                      9
                                                          10
add r1, r2, r3 IF
                     ID
                         EX
                             MEM WB
sub r4, r1, r5
                     IF
                         ID
                                     EX
                                         MEM WB
and r6, r1, r8
                                     ID
                                         EX
                                              MEM WB
xor r9, r4, r11
                                     IF
                                                 EX
                                         ID
                                              ->
                                                      MEM WB
```

Arrow shows that instructions stalled.

Stall creates a bubble, segments without valid instructions, in the pipeline.

With bubbles present, CPI is greater than its ideal value of 1.

## Stall Implementation

Stall implemented by asserting a *hold* signal . . .

- ... which inserts a nop (or equivalent) after the stalling instruction and ...
- ... disables clocking of pipeline latches before the stalling instruction.

```
! Cycle
                             3
                                     5
                                         6
                                             7
                                                 8
                                                          10
                                                     9
add r1, r2, r3 IF ID
                        ΕX
                             MEM WB
   r4, r1, r5
                     IF
sub
                         ID
                                     EX
                                         MEM WB
and r6, r1, r8
                         TF
                                         EX
                                     ID
                                             MEM WB
xor r9, r4, r11
                                     IF
                                         ID
                                                 EX
                                                     MEM WB
```

During cycle 3, a nop is in EX.

During cycle 4, a nop is in EX and MEM.

The two adjacent nops are called a bubble ...

... they move through the pipeline with the other instructions.

A third nop is in EX in cycle 7.

Some stalls are avoidable.

### Consider again:

```
! Cycle
                  0
                       1
                           2
                                        5
                                             6
                                                 7
                                                     8
                                                          9
                                                              10
                                3
                                    4
add r1, r2, r3
                  _{
m IF}
                      ID
                           EX
                               MEM WB
sub r4, r1, r5
                      IF
                           ID
                               EX
                                    MEM WB
and r6, r1, r8
                           IF
                               ID
                                    EX
                                        MEM WB
xor r9, r4, r11
                               IF
                                    ID
                                        EX
                                             MEM WB
```

Note that the new value of r1 needed by sub ...

- ... has been computed at the end of cycle 2 ...
- ... and isn't really needed until the beginning of the next cycle, 3.

Execution was incorrect because the value had to go around the pipeline to ID.

Why not provide a shortcut?

Why not call a shortcut a bypass or forwarding path?

# MIPS Implementation With Some Forwarding Paths:

```
! Cycle
add r1, r2, r3 IF
                     ID
                          EX
                              MEM WB
    r4, r1, r5
sub
                      _{
m IF}
                              EX
                                  MEM WB
and r6, r1, r8
                          IF
                              ID
                                  EX
                                       MEM WB
xor r9, r4, r11
                              IF
                                  ID
                                       EX
                                           MEM WB
```

It works!

Not all stalls are avoidable.

```
! Cycle
     r1, 0(r2)
lw
                              MEM WB
                      ID
                          ΕX
add r1, r1, r4
                      IF
                          ID
                                   EX
                                       MEM WB
                              ->
     4(r2), r1
                          IF
SW
                              ->
                                   ID
                                               EX
                                                    MEM WB
addi r2, r2, 8
                                               ID
                                                    EX
                                                        MEM WB
```

Stall due to lw could not be avoided (data not available in cycle 3).

Stall in cycles 5 and 6 could be avoided with a new forwarding path.

Start with logic for rd, show path of Mux logic.

# Bypass Control Logic for Lower ALU Mux

Control logic not minimized (for clarity).

Control Logic Generating ID/EX.RD.

Present in previous implementations, just not shown.

Determines which register gets written based on instruction.

Instruction categories used in boxes such as **= Load** (some instructions omitted):

- = Non-link CTI: branches and jumps except linking jumps (jal and jalr).
- = Store : All store instructions.
- = Type I ALU: All Type I ALU instructions.
- = Load : All load instructions.
- = Type R : All Type R instructions.
- = Link CTI : jal and jalr.

Logic Generating ID/EX.MUX.

=' box determines if two register numbers are equal.

Register number zero is not equal register zero, nor any other register.

(The bypassed zero value might not be zero.)

Cause: on taken CTI several wrong instructions fetched.

Consider:

```

Branch is taken yet two instructions past delay slot (sub) complete execution.

Branch target finally fetched in cycle 4.

Problem: Two instructions following delay slot.

## Handling Instructions Following a Taken Branch Delay Slot

## Option 1: Don't fetch them.

Possible (with pipelining) because ...

... fetch starts (sw in cycle 2) ...

... after branch decoded.

(Would be impossible ...

... for non-delayed branch.)

```
!I Adr

```

Handling Instructions Following a Taken Branch

Option 2: Fetch them, but squash (stop) them in a later stage.

This will work if instructions squashed ...

... before modifying architecturally visible storage (registers and memory).

Memory modified in MEM stage and registers modified in WB stage ...

... so instructions must be stopped before beginning of MEM stage.

Can we do it? Depends depends where branch instruction is.

In example, need to squash sw before cycle 5.

During cycle 3 bgtz in MEM ...

... it has been decoded and the branch condition is available ...

... so we know whether the branch is taken ...

... so sw can easily be squashed before cycle 5.

Option 2 will be used.

## In-Flight Instruction::

An instruction in the execution pipeline.

Later in the semester a more specific definition will be used.

```
Squashing:: [an instruction]
preventing an in-flight instruction ...
... from writing registers, memory or any other visible storage.
```

Squashing also called: *nulling*, *abandoning*, and *cancelling*..

Like an insect, a squashed instruction is still there (in most cases) but can do no harm.

Two ways to squash.

• Prevent it from writing architecturally visible storage.

Replace destination register control bits with zero. (Writing zero doesn't change anything.)

Set memory control bits (not shown so far) for no operation.

• Change Operation to nop.

Would require changing many control bits.

Squashing shown that way here for brevity.

Illustrated by placing a nop in IR.

Why not replace squashed instructions with target instructions?

Because there is no straightforward and inexpensive way ...

... to get the instructions where and when they are needed.

(Curvysideways and expensive techniques covered in Chapter 4.)

MIPS implementation used so far.

### Example of correct execution

```
!I Adr
                Cycle
                                 2
                                     3
                                          4
                                              5
                                                  6
                                                      7
                                                          8
       bgtz r4, TARGET
0x100
                         IF
                             ID
                                 EX
                                     MEM WB
       sub r4, r2, r5
0x104
                             IF
                                 ID
                                     EX
                                         MEM WB
0x108
            0(r2), r1
       SW
                                 IF
                                     IDx
       and r6, r1, r8
0x10c
                                     IFx
            r12, r13, r14
0x110 or
           TARGET = 0x200
TARGET: !
0x200
      xor r9, r4, r11
                                                      MEM WB
                                          IF
                                              ID
                                                  EX
```

Branch outcome known at end of cycle 2 ...

- ... wait for cycle 3 when doomed instructions (sw and and) in flight ...
- ... and squash them so in cycle 4 they act like nops.

Two cycles (1, 2, and 3), are lost.

Two cycles called a branch penalty.

Two cycles is alot of cycles, is there something we can do?

Compute branch target address in ID stage.

Compute branch target and condition in ID stage.

Workable because register values not needed to compute branch address and ... ... branch condition can be computed quickly.

Now how fast will code run?

```
7
!I Adr
                Cycle
                                2
                                     3
                                         4
                                             5
                                                 6
                                                         8
                            1
      bgtz r4, TARGET IF
0x100
                                EX
                                    MEM WB
                            {	t ID}
0x104
       sub r4, r2, r5
                            IF
                                ID
                                    EX
                                        MEM WB
            0(r2), r1
0x108
0x10c
       and r6, r1, r8
0x110 or
           r12, r13, r14
           TARGET = 0x200
TARGET: !
0x200 xor r9, r4, r11
                                            MEM WB
                                        EX
                                IF
                                     ID
```

No penalty, not a cycle wasted!!
