9 Shading Language Grammar

10 Issues
This document specifies only version 1.30 of the OpenGL Shading Language. It requires __VERSION__ to substitute 130 or 120, and requires #version to accept only 130 or 120. If #version is declared with 110 or 120, the language accepted is a previous version of the shading language, which will be supported depending on the version and type of context in the OpenGL API. See the OpenGL Graphics System Specification, Version 3.0, for details on what language versions are supported.

1.1 Acknowledgments

This specification is based on the work of those who contributed to version 1.10 of the OpenGL Language Specification, the OpenGL ES 2.0 Language Specification, version 1.10, and the following contributors to this version:

Rob Barris
Pierre Boudier
Pat Brown
Nick Burns
Chris Dodd
Michael Gold
Nick Haemel
James Helferty
Brent Insko
Jeff Juliano
Jon Leech
Bill Licea-Kane
Barthold Lichtenbelt
Daniel Koch
Benjamin Lipechak
Marc Olano
Ian Romanick
John Rosasco
Dave Shreiner
Jeremy Sandmel
Robert Simpson
Eskil Steenberg

1.2 Changes

1.2.1 Summary of Functionality differences from version 1.2

The following is a summary of features added in version 1.3:

- Integer support:
1 Introduction

- native signed and unsigned integers, integer vectors, and operations
- bitwise shifts and masking
- texture indices
- texture return values
- integer uniforms, vertex inputs, vertex outputs, fragment inputs, and fragment outputs
- built-in function support: abs, sign, min, max, clamp, ...

Other texture support:
- Size queries.
- Texture arrays.
- Offsetting.
- Explicit LOD and derivative controls

switch/case/default statements.

New built-ins: trunc(), round(), roundEven(), isnan(), isinf(), modf()  
hyperbolic trigonometric functions.
Preprocessor token pasting (##).
User-defined fragment output variables.
Shader input and output declarations via in and out.
Improved compatibility with OpenGL ES  
non-perspective (linear) interpolation (nosperspective)
new vertex input gl_VertexID.

The following is a summary of features deprecated in version 1.3:
- Use of the keywords attribute and varying (use in and out).
- Use of gl_ClipVertex (use gl_ClipDistance)
- Use of gl_FragData and gl_FragColor (use user-defined out instead).
- Built-in attributes. Use user-defined vertex inputs instead.
- Fixed function vertex or fragment stages mixed with shader programs. Provide shaders for all active programmable pipeline stages.
- All built-in texture function names. See new names.
- Use of the built-in varyings gl_FogFragCoord and gl_TexCoord. Use user-defined variable instead.
- The built in function ftransform. Use the invariant qualifier on a vertex output instead.
- Most built-in state.
- gl_MaxVaryingFloats (use gl_MaxVaryingComponents instead)
1 Introduction

The following is a summary of features that have been removed in version 1.3:

- None, only deprecations occurred in this release.

1.2.2 Change history of this revision

Changes from revisions 6 and 7 of version 1.30 of the OpenGL Shading Language

- Fix all references to the OpenGL Graphics System specification, including matching notation for texturing parameters.

Changes from revision 5 of version 1.30 of the OpenGL Shading Language

- Reserved superp.
- Made it an error to specify integer literals too big for an integer variable.
- Increased
  - gl_MaxVaryingComponents to 64
  - gl_MaxDrawBuffers to 8
  - gl_MaxTextureCoordinates to 8
- Fixed some typos.

Changes from revision 4 of version 1.30 of the OpenGL Shading Language

- Updated acknowledgments; let me know if anyone is missing.
- Added summary lists of what’s deprecated, removed, and added
- Deprecated fixed functionality control of a programmable stage
- flat is for both user and predeclared built-in in/out variables
- only statically used built-ins have to be redeclared as flat
- Made more clear that 1.1 and 1.2 shaders work, depending on state of the API
- Made clear ## does macro expansion after pasting not before
- ftransform() is deprecated instead of removed
- built-in state is deprecated instead of removed
- highp is always present in the fragment language, the default is highp
- order of qualification is either (invariant-qualifier interpolation-qualifier storage-qualifier precision-qualifier) or (storage-qualifier parameter-qualifier precision-qualifier)
- uint and int can be mixed for <<, >> but not for other operators
- combined descriptions of << and >>, and also of &, +, and ^
- switch statements can be empty, must have a statement between a label and the end of the switch, allows fall throughs
• updated the minimum maximums and added gl_MaxVaryingComponents and deprecated gl_MaxVaryingFloats
• added gl_ClipDistance[] to the fragment side
• Removed #include support
• Removed row_major
• Removed common blocks
• OpenGL ES synchronization
  ○ (a = b) is an r-value and never an l-value
• Updated the grammar with I have added these to the grammar
  ○ switch statement
  ○ case/default labels, which are mixed with other statements (needs semantic check for in switch)
  ○ uint, unsigned literals, unsigned vectors
  ○ 17 new sampler types
  ○ new storage qualifiers in, out, centroid in, centroid out (detangled from parameter in/out/inout)
  ○ interpolation qualifiers noperspective, flat, smooth
  ○ precision qualifiers
  ○ allowed bitwise and shift operators

Changes from revision 3 of version 1.30 of the OpenGL Shading Language
• Added deprecation section 1.6
• Added user-defined fragment shader outputs.
• Remove most built-in state.
• Deprecated built-in vertex inputs (attributes) and some outputs (varyings).
• Added gl_ClipDistance.
• Deprecated mixing fixed vertex/fragment stage with programmable fragment/vertex stage.
• Removed support for multiple programs tiling the pipeline (still original 1.2 model of one program for the whole pipeline).
• Removed inout as a way of declaring interface variables, to avoid the problem of things like interpolation qualifiers not knowing if they are modifying the copy in or the copy out. Also removes the problem of implicit pass through for a variable declared inout but never used.
• True native integer support
  • signed and unsigned integer semantics
  • bitwise operators and shifts
1 Introduction

- built-in functions operating on integers, `abs, sign, min, max, clamp`
- integer-based texture lookup functions, texel fetch
- texture arrays
- projective cube map texture and shadow
- explicit gradient texture lookup
- offset-texel texture lookup
- texture size functions
- added `noperspective` interpolation qualifier
- added `trunc, round, roundEven, modf`
- removed `ftransform`
- added `isinf` and `isnan`
- added hyperbolic functions `sinh, cosh, tanh, asinh, acosh, atanh`
- some synchronization with ES (inout parameter evaluation order, foo(void), others)
- deprecated `gl_ClipVertex`
- added `gl_VertexID`
- it's an error to use `#if` etc. on an undefined name

Changes from revision 2 of version 1.30 of the OpenGL Shading Language
- large rework of section 8.7 Texture Lookup Functions. Dropped dimensionality/shadow from the names, organized by type instead of dimensionality, added in Lod control.
- use gl_Position for clipping if `gl_ClipVertex` is not statically written.
- remove language about the fixed pipeline in the description of `ftransform()`.

Changes from revision 10 of version 1.20 of the OpenGL Shading Language
- `in, out, and inout` are used at global scope as the preferred way of declaring attributes, varyings, and fragment shader outputs. This eases the usage of `centroid, flat, smooth, invariant, etc.` by reducing the number of keywords needed to declare a variable, removes the misnomer that flat variables vary, provides for a default interpolation, and scales to additional future programmable pipe stages.
- common blocks are added and can be backed by buffers in the API.
- “gl_” prefixed uniforms and attributes and several of the varyings no longer reflect built-in state, but are predeclared by the language as a convenience to the user.
- the ability to index into an array of samplers with a variable index is removed.
- token pasting (`##`) is added to the preprocessor.
- add `row_major` to support row-major matrices to allow packing of a 3-row 4-column matrix into 3 uniforms or 3 attributes.
1 Introduction

• Support `#include` via named source strings.
• Accept the precision qualifiers from OpenGL ES with no expectation that anything is done with them.
• `switch` statements are added for integer scalars only
• `mix()` is expanded to operate on a Boolean 3rd argument that does not interpolate but selects.

1.3 Overview

This document describes The OpenGL Shading Language, version 1.20.30. Independent compilation units written in this language are called shaders. A program is a complete set of shaders that are compiled and linked together. The aim of this document is to thoroughly specify the programming language. The OpenGL API Graphics System Specification will specify the OpenGL entry points used to manipulate and communicate with programs and shaders.

1.4 Error Handling

Compilers, in general, accept programs that are ill-formed, due to the impossibility of detecting all ill-formed programs. Portability is only ensured for well-formed programs, which this specification describes. Compilers are encouraged to detect ill-formed programs and issue diagnostic messages, but are not required to do so for all cases. Compilers are required to return messages regarding lexically, grammatically, or semantically incorrect shaders.

1.5 Typographical Conventions

Italic, bold, and font choices have been used in this specification primarily to improve readability. Code fragments use a fixed width font. Identifiers embedded in text are italicized. Keywords embedded in text are bold. Operators are called by their name, followed by their symbol in bold in parentheses. The clarifying grammar fragments in the text use bold for literals and italics for non-terminals. The official grammar in Section 9 “Shading Language Grammar” uses all capitals for terminals and lower case for non-terminals.

1.6 Deprecation

This version of the OpenGL Shading Language deprecates some features. These are clearly called out in this specification as “deprecated”. They are still present in this version of the language, but are targeted for potential removal in a future version of the shading language. The OpenGL API has a forward compatibility mode that will disallow use of deprecated features. If compiling in a mode where use of deprecated features is disallowed, their use causes compile time errors. See the OpenGL Graphics System Specification for details on what causes deprecated language features to be accepted or to return an error.
2 Overview of OpenGL Shading

The OpenGL Shading Language is actually two closely related languages. These languages are used to create shaders for the programmable processors contained in the OpenGL processing pipeline.

Unless otherwise noted in this paper, a language feature applies to all languages, and common usage will refer to these languages as a single language. The specific languages will be referred to by the name of the processor they target: vertex or fragment.

Most OpenGL state is not tracked or made available to shaders. Typically, user-defined variables will be used for communicating between different stages of the OpenGL pipeline. However, a small amount of state is still tracked and automatically made available to shaders, and there are a few built-in variables for interfaces between different stages of the OpenGL pipeline. This automatic state tracking mechanism allows the application to use existing OpenGL state commands for state management and have the current values of such state automatically available for use in a shader. Any OpenGL state used by the shader is automatically tracked and made available to shaders.

2.1 Vertex Processor

The vertex processor is a programmable unit that operates on incoming vertices and their associated data. Compilation units written in the OpenGL Shading Language to run on this processor are called vertex shaders. When a complete set of vertex shaders are compiled and linked, they result in a vertex shader executable that runs on the vertex processor.

The vertex processor operates on one vertex at a time. It does not replace graphics operations that require knowledge of several vertices at a time. The vertex shaders running on the vertex processor must compute the homogeneous position of the incoming vertex.

2.2 Fragment Processor

The fragment processor is a programmable unit that operates on fragment values and their associated data. Compilation units written in the OpenGL Shading Language to run on this processor are called fragment shaders. When a complete set of fragment shaders are compiled and linked, they result in a fragment shader executable that runs on the fragment processor.

A fragment shader cannot change a fragment's (x, y) position. Access to neighboring fragments is not allowed. The values computed by the fragment shader are ultimately used to update frame-buffer memory or texture memory, depending on the current OpenGL state and the OpenGL command that caused the fragments to be generated.
3 Basics

3.1 Character Set

The source character set used for the OpenGL shading languages is a subset of ASCII. It includes the following characters:

The letters a-z, A-Z, and the underscore (_).

The numbers 0-9.

The symbols period (.), plus (+), dash (-), slash (/), asterisk (*), percent (%), angled brackets (< and >), square brackets ([ and ]), parentheses ( ( and ) ), braces ( { and } ), caret (^), vertical bar ( | ), ampersand (&), tilde (~), equals (=), exclamation point (!), colon (:), semicolon (;), comma (,), and question mark (?)

The number sign (#) for preprocessor use.

White space: the space character, horizontal tab, vertical tab, form feed, carriage-return, and line-feed.

Lines are relevant for compiler diagnostic messages and the preprocessor. They are terminated by carriage-return or line-feed. If both are used together, it will count as only a single line termination. For the remainder of this document, any of these combinations is simply referred to as a new-line. There is no line continuation character.

In general, the language’s use of this character set is case sensitive.

There are no character or string data types, so no quoting characters are included.

There is no end-of-file character. The end of a source string is indicated by a length, not a character.

3.2 Source Strings

The source for a single shader is an array of strings of characters from the character set. A single shader is made from the concatenation of these strings. Each string can contain multiple lines, separated by new-lines. No new-lines need be present in a string; a single line can be formed from multiple strings. No new-lines or other characters are inserted by the implementation when it concatenates the strings to form a single shader. Multiple shaders can be linked together to form a single program.

Diagnostic messages returned from compiling a shader must identify both the line number within a string and which source string the message applies to. Source strings are counted sequentially with the first string being string 0. Line numbers are one more than the number of new-lines that have been processed.
3.3 Preprocessor

There is a preprocessor that processes the source strings as part of the compilation process.

The complete list of preprocessor directives is as follows.

```
# define
# undef

#if
#define
#endif
#else
#endif
#elif
#endif
#error
#pragma

#define
#endif
#endif
#define
#endif
#endif
#endif
 gà
#if
#define
#endif
#endif
#endif
#elif
#endif
#error
#pragma

#define
#endif
#endif
#define
#endif
#endif
#endif
#elif
#endif
#error
#pragma
```

The following operators are also available

```
#define
#endif
```

Each number sign (#) can be preceded in its line only by spaces or horizontal tabs. It may also be
followed by spaces and horizontal tabs, preceding the directive. Each directive is terminated by a new-
line. Preprocessing does not change the number or relative location of new-lines in a source string.

The number sign (#) on a line by itself is ignored. Any directive not listed above will cause a diagnostic
message and make the implementation treat the shader as ill-formed.

#define and #undef functionality are defined as is standard for C++ preprocessors for macro definitions
both with and without macro parameters.

The following predefined macros are available

```
__LINE__
__FILE__
__VERSION__
```

__LINE__ will substitute a decimal integer constant that is one more than the number of preceding new-
lines in the current source string.

__FILE__ will substitute a decimal integer constant that says which source string number is currently
being processed.
__VERSION__ will substitute a decimal integer reflecting the version number of the OpenGL shading language. The version of the shading language described in this document will have __VERSION__ substitute the decimal integer 120.

All macro names containing two consecutive underscores (__) are reserved for future use as predefined macro names. All macro names prefixed with “GL_” (“GL” followed by a single underscore) are also reserved.

#if, #ifdef, #ifndef, #else, #elif, and #endif are defined to operate as is standard for C++ preprocessors. Expressions following #if and #elif are further restricted to expressions operating on literal integer constants, plus identifiers consumed by the defined operator. It is an error to use #if or #elif on expressions containing undefined macro names, other than as arguments to the defined operator. Character constants are not supported. The operators available are as follows.

<table>
<thead>
<tr>
<th>Precedence</th>
<th>Operator class</th>
<th>Operators</th>
<th>Associativity</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (highest)</td>
<td>parenthetical grouping</td>

</tr>
</tbody>
</table>

The defined operator can be used in either of the following ways:

```c
defined identifier
defined ( identifier )
```

Two tokens in a macro can be concatenated into one token using the token pasting (##) operator, as is standard for C++ preprocessors. The result must be a valid single token, which will then be subject to macro expansion. That is, macro expansion happens after token pasting and does not happen before token pasting. There are no other number sign based operators (e.g. no #, #@, ##, etc.), nor is there a sizeof.

The semantics of applying operators to integer literals in the preprocessor match those standard in the C++ preprocessor, not those in the OpenGL Shading Language.
Preprocessor expressions will be evaluated according to the behavior of the host processor, not the processor targeted by the shader.

`#error` will cause the implementation to put a diagnostic message into the shader object’s information log (see the API in external documentation OpenGL Graphics System Specification for how to access a shader object’s information log). The message will be the tokens following the `#error` directive, up to the first new-line. The implementation must then consider the shader to be ill-formed.

`#pragma` allows implementation dependent compiler control. Tokens following `#pragma` are not subject to preprocessor macro expansion. If an implementation does not recognize the tokens following `#pragma`, then it will ignore that pragma. The following pragmas are defined as part of the language.

`#pragma STDGL`  
The STDGL pragma is used to reserve pragmas for use by future revisions of this language. No implementation may use a pragma whose first token is STDGL.

`#pragma optimize(on)`
`#pragma optimize(off)`  
These can be used to turn off optimizations as an aid in developing and debugging shaders. It can only be used outside function definitions. By default, optimization is turned on for all shaders. The debug pragma

`#pragma debug(on)`
`#pragma debug(off)`  
These can be used to enable compiling and annotating a shader with debug information, so that it can be used with a debugger. It can only be used outside function definitions. By default, debug is turned off.

Shaders should declare the version of the language they are written to. The language version a shader is written to is specified by

`#version number`  
where `number` must be a version of the language, following the same convention as `_VERSION_` above.

The directive “`#version 120`”`#version 130`” is required in any shader that uses version `1.20` of the language. Any `number` representing a version of the language a compiler does not support will cause an error to be generated. Version `1.10` of the language does not require shaders to include this directive, and shaders that do not include a `#version` directive will be treated as targeting version `1.10`. The behavior of shaders targeting version `1.10` will not be effected by any changes introduced in version `1.20`. Different shaders (compilation units) that are linked together in the same program do not have to have the same version; they can be a mix of version `1.10` and version `1.20` shaders.

The `#version` directive must occur in a shader before anything else, except for comments and white space.
By default, compilers of this language must issue compile time syntactic, grammatical, and semantic errors for shaders that do not conform to this specification. Any extended behavior must first be enabled. Directives to control the behavior of the compiler with respect to extensions are declared with the \texttt{#extension} directive

\begin{verbatim}
#extension extension_name : behavior
#extension all : behavior
\end{verbatim}

where \textit{extension\_name} is the name of an extension. Extension names are not documented in this specification. The token \textit{all} means the behavior applies to all extensions supported by the compiler. The \textit{behavior} can be one of the following

<table>
<thead>
<tr>
<th>\textit{behavior}</th>
<th>\textit{Effect}</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{require}</td>
<td>Behave as specified by the extension \textit{extension_name}.\nGive an error on the \texttt{#extension} if the extension \textit{extension_name} is not supported, or if \textit{all} is specified.</td>
</tr>
<tr>
<td>\textit{enable}</td>
<td>Behave as specified by the extension \textit{extension_name}.\nWarn on the \texttt{#extension} if the extension \textit{extension_name} is not supported.\nGive an error on the \texttt{#extension} if \textit{all} is specified.</td>
</tr>
<tr>
<td>\textit{warn}</td>
<td>Behave as specified by the extension \textit{extension_name}, except issue warnings on any detectable use of that extension, unless such use is supported by other enabled or required extensions.\nIf \textit{all} is specified, then warn on all detectable uses of any extension used.\nWarn on the \texttt{#extension} if the extension \textit{extension_name} is not supported.</td>
</tr>
<tr>
<td>\textit{disable}</td>
<td>Behave (including issuing errors and warnings) as if the extension \textit{extension_name} is not part of the language definition.\nIf \textit{all} is specified, then behavior must revert back to that of the non-extended core version of the language being compiled to.\nWarn on the \texttt{#extension} if the extension \textit{extension_name} is not supported.</td>
</tr>
</tbody>
</table>

The \textit{extension} directive is a simple, low-level mechanism to set the behavior for each extension. It does not define policies such as which combinations are appropriate, those must be defined elsewhere. Order of directives matters in setting the behavior for each extension: Directives that occur later override those seen earlier. The \textit{all} variant sets the behavior for all extensions, overriding all previously issued \textit{extension} directives, but only for the \textit{behaviors warn} and \textit{disable}. 

12
The initial state of the compiler is as if the directive

```c
#extension all : disable
```

was issued, telling the compiler that all error and warning reporting must be done according to this specification, ignoring any extensions.

Each extension can define its allowed granularity of scope. If nothing is said, the granularity is a shader (that is, a single compilation unit), and the extension directives must occur before any non-preprocessor tokens. If necessary, the linker can enforce granularities larger than a single compilation unit, in which case each involved shader will have to contain the necessary extension directive.

Macro expansion is not done on lines containing `#extension` and `#version` directives. `#line` must have, after macro substitution, one of the following two forms:

```c
#line line
#line line source-string-number
```

where `line` and `source-string-number` are constant integer expressions. After processing this directive (including its new-line), the implementation will behave as if it is compiling at line number `line+1` and source string number `source-string-number`. Subsequent source strings will be numbered sequentially, until another `#line` directive overrides that numbering.

### 3.4 Comments

Comments are delimited by /* and */, or by // and a new-line. The begin comment delimiters (/* or //) are not recognized as comment delimiters inside of a comment, hence comments cannot be nested. If a comment resides entirely within a single line, it is treated syntactically as a single space. New-lines are not eliminated by comments.

### 3.5 Tokens

The language is a sequence of tokens. A token can be

```c
token:
    keyword
    identifier
    integer-constant
    floating-constant
    operator
    ; { }```

3.6 Keywords

The following are the keywords in the language, and cannot be used for any other purpose than that
defined by this document:

```
__attribute const uniform varying
centroid _flat _smooth _noperspective
break continue do for while__switch case default
if else
in out inout
float int void bool true false
invariant
discard return
mat2 mat3 mat4
mat2x2 mat2x3 mat2x4
mat3x2 mat3x3 mat3x4
mat4x2 mat4x3 mat4x4
vec2 vec3 vec4 ivec2 ivec3 ivec4 bvec2 bvec3 bvec4
__uint __uvec2 __uvec3 __uvec4
__lowp __mediump __highp __precision
sampler1D sampler2D sampler3D samplerCube
sampler1DShadow sampler2DShadow__samplerCubeShadow
__sampler1DArray__sampler2DArray
__sampler1DArrayShadow__sampler2DArrayShadow
__isampler1D__isampler2D__isampler3D__isamplerCube
__isampler1DArray__isampler2DArray
__usampler1D__usampler2D__usampler3D__usamplerCube
__usampler1DArray__usampler2DArray
struct
```

The following are the keywords reserved for future use. Using them will result in an error:

```
__common__partition__active
__asm
```
class union enum typedef template this packed
goto switch default
inline noinline volatile public static extern external interface
long short double half fixed unsigned superp
lowp mediump highp precision
input output
hvec2 hvec3 hvec4 dvec2 dvec3 dvec4 fvec2 fvec3 fvec4
sampler2DRect sampler3DRect sampler2DRectShadow
  __samplerBuffer
  __filter_
    __image1D_image2D_image3D_imageCube_
    __iimage1D_iimage2D_iimage3D_iimageCube_
    __uimage1D_uimage2D_uimage3D_uimageCube_
    __image1DArray__image2DArray__
    __iimage1DArray__iimage2DArray__uimage1DArray__uimage2DArray__
    __image1DShadow__image2DShadow__
    __image1DArrayShadow__image2DArrayShadow__
    __imageBuffer__iimageBuffer__uimageBuffer__
  sizeof cast
  namespace using
  __row_major

In addition, all identifiers containing two consecutive underscores (__ are reserved as possible future keywords.

3.7 Identifiers

Identifiers are used for variable names, function names, struct names, and field selectors (field selectors select components of vectors and matrices similar to structure fields, as discussed in Section 5.5 “Vector Components” and Section 5.6 “Matrix Components” ). Identifiers have the form

\[ identifier \]
\[ nondigit \]
\[ identifier nondigit \]
\[ identifier digit \]

\[ nondigit: \text{one of } \_] a b c d e f g h i j k l m n o p q r s t u v w x y z\]
\[ A B C D E F G H I J K L M N O P Q R S T U V W X Y Z \]
3 Basics

Identifiers starting with “gl_” are reserved for use by OpenGL, and may not be declared in a shader as either a variable or a function. However, as noted in the specification, there are some cases where previously declared variables can be redeclared to change some property, and predeclared "gl_” names are allowed to be redeclared in a shader.

3.8 Static Use

Some language rules described below depend on whether something is statically written or used. A shader contains a static use of (or static assignment to) a variable \( x \) if, after preprocessing, the shader contains a statement that would read (or write) \( x \), whether or not run-time flow of control will cause that statement to be executed.
4 Variables and Types

All variables and functions must be declared before being used. Variable and function names are identifiers.

There are no default types. All variable and function declarations must have a declared type, and optionally qualifiers. A variable is declared by specifying its type followed by one or more names separated by commas. In many cases, a variable can be initialized as part of its declaration by using the assignment operator (=). The grammar near the end of this document provides a full reference for the syntax of declaring variables.

User-defined types may be defined using `struct` to aggregate a list of existing types into a single name.

The OpenGL Shading Language is type safe. There are no implicit conversions between types, with the exception that an integer value may appear where a floating-point type is expected, and be converted to a floating-point value. Exactly how and when this can occur is described in Section 4.1.10 “Implicit Conversions” and as referenced by other sections in this specification.

4.1 Basic Types

The OpenGL Shading Language supports the following basic data types, grouped as follows.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td>for functions that do not return a value</td>
</tr>
<tr>
<td>bool</td>
<td>a conditional type, taking on values of true or false</td>
</tr>
<tr>
<td>int</td>
<td>a signed integer</td>
</tr>
<tr>
<td>uint</td>
<td>an unsigned integer</td>
</tr>
<tr>
<td>float</td>
<td>a single floating-point scalar</td>
</tr>
<tr>
<td>vec2</td>
<td>a two component floating-point vector</td>
</tr>
<tr>
<td>vec3</td>
<td>a three component floating-point vector</td>
</tr>
<tr>
<td>vec4</td>
<td>a four component floating-point vector</td>
</tr>
<tr>
<td>bvec2</td>
<td>a two component Boolean vector</td>
</tr>
<tr>
<td>bvec3</td>
<td>a three component Boolean vector</td>
</tr>
<tr>
<td>bvec4</td>
<td>a four component Boolean vector</td>
</tr>
<tr>
<td>ivec2</td>
<td>a two-component <code>signed</code> integer vector</td>
</tr>
<tr>
<td>ivec3</td>
<td>a three-component <code>signed</code> integer vector</td>
</tr>
<tr>
<td>ivec4</td>
<td>a four-component <code>signed</code> integer vector</td>
</tr>
<tr>
<td>Type</td>
<td>Meaning</td>
</tr>
<tr>
<td>----------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>uvec2</td>
<td>a two-component unsigned integer vector</td>
</tr>
<tr>
<td>uvec3</td>
<td>a three-component unsigned integer vector</td>
</tr>
<tr>
<td>uvec4</td>
<td>a four-component unsigned integer vector</td>
</tr>
<tr>
<td>mat2</td>
<td>a 2×2 floating-point matrix</td>
</tr>
<tr>
<td>mat3</td>
<td>a 3×3 floating-point matrix</td>
</tr>
<tr>
<td>mat4</td>
<td>a 4×4 floating-point matrix</td>
</tr>
<tr>
<td>mat2x2</td>
<td>same as a mat2</td>
</tr>
<tr>
<td>mat2x3</td>
<td>a floating-point matrix with 2 columns and 3 rows</td>
</tr>
<tr>
<td>mat2x4</td>
<td>a floating-point matrix with 2 columns and 4 rows</td>
</tr>
<tr>
<td>mat3x2</td>
<td>a floating-point matrix with 3 columns and 2 rows</td>
</tr>
<tr>
<td>mat3x3</td>
<td>same as a mat3</td>
</tr>
<tr>
<td>mat3x4</td>
<td>a floating-point matrix with 3 columns and 4 rows</td>
</tr>
<tr>
<td>mat4x2</td>
<td>a floating-point matrix with 4 columns and 2 rows</td>
</tr>
<tr>
<td>mat4x3</td>
<td>a floating-point matrix with 4 columns and 3 rows</td>
</tr>
<tr>
<td>mat4x4</td>
<td>same as a mat4</td>
</tr>
<tr>
<td>sampler1D</td>
<td>a handle for accessing a 1D texture</td>
</tr>
<tr>
<td>sampler2D</td>
<td>a handle for accessing a 2D texture</td>
</tr>
<tr>
<td>sampler3D</td>
<td>a handle for accessing a 3D texture</td>
</tr>
<tr>
<td>samplerCube</td>
<td>a handle for accessing a cube mapped texture</td>
</tr>
<tr>
<td>sampler1DShadow</td>
<td>a handle for accessing a 1D depth texture with comparison</td>
</tr>
<tr>
<td>sampler2DShadow</td>
<td>a handle for accessing a 2D depth texture with comparison</td>
</tr>
</tbody>
</table>

**Floating Point Sampler Types (opaque)**

<tr>
<td>usampler1DArray</td>
<td>a handle for accessing an unsigned integer 1D array texture</td>
</tr>
<tr>
<td>usampler2DArray</td>
<td>a handle for accessing an unsigned integer 2D array texture</td>
</tr>
</tbody>
</table>

In addition, a shader can aggregate these using arrays and structures to build more complex types.

There are no pointer types.

4.1.1 Void

Functions that do not return a value must be declared as `void`. There is no default function return type. The keyword `void` cannot be used in any other declarations (except for empty formal or actual parameter lists).

4.1.2 Booleans

To make conditional execution of code easier to express, the type `bool` is supported. There is no expectation that hardware directly supports variables of this type. It is a genuine Boolean type, holding only one of two values meaning either true or false. Two keywords `true` and `false` can be used as literal Boolean constants. Booleans are declared and optionally initialized as in the follow example:
bool success;    // declare "success" to be a Boolean
bool done = false; // declare and initialize "done"

The right side of the assignment operator (=) can be any must be an expression whose type is bool.
Expressions used for conditional jumps (if, for, ?:, while, do-while) must evaluate to the type bool.

4.1.3 Integers

Integers are mainly supported as a programming aid. At the hardware level, real integers would aid efficient implementation of loops and array indices, and referencing texture units. However, there is no requirement that integers in the language map to an integer type in hardware. It is not expected that underlying hardware has full support for a wide range of integer operations. Because of their intended (limited) purpose, integers are limited to 16 bits of precision, plus a sign representation in both the vertex and fragment languages. An OpenGL Shading Language implementation may convert integers to floats to operate on them. An implementation is allowed to use more than 16 bits of precision to manipulate integers. Hence, there is no portable wrapping behavior. Shaders that overflow the 16 bits of precision may not be portable.

Signed and unsigned integer variables are fully supported. In this document, the term integer is meant to generally include both signed and unsigned integers. Unsigned integers have exactly 32 bits of precision. Signed integers use 32 bits, including a sign bit, in two's complement form. Operations resulting in overflow or underflow will not cause any exception, nor will they saturate, rather they will "wrap" to yield the low-order 32 bits of the result.

Integers are declared and optionally initialized with integer expressions, as in the following example:

int i, j = 42;  // default integer literal type is int
uint k = 3u;    // "u" establishes the type as uint

Literal integer constants can be expressed in decimal (base 10), octal (base 8), or hexadecimal (base 16) as follows.

integer-constant :
  decimal-constant integer-suffix
  octal-constant integer-suffix
  hexadecimal-constant integer-suffix

integer-suffix: one of
  u U

decimal-constant :
  nonzero-digit
  decimal-constant digit

octal-constant :
  0
  octal-constant octal-digit
4 Variables and Types

```
4.1.4 Floats

Floats are available for use in a variety of scalar calculations. Floating-point variables are defined as in the following example:

```c
float a, b = 1.5;
```

As an input value to one of the processing units, a floating-point variable is expected to match the IEEE single precision floating-point definition for precision and dynamic range. It is not required that the precision of internal processing match the IEEE floating-point specification for floating-point operations, but the guidelines for precision established by the OpenGL 1.4 specification must be met. Similarly, treatment of conditions such as divide by 0 may lead to an unspecified result, but in no case should such a condition lead to the interruption or termination of processing.

Floating-point constants are defined as follows.

```plaintext
floating-constant :
  fractional-constant exponent-part opt floating-suffix opt
digit-sequence exponent-part floating-suffix opt
```
4 Variables and Types

fractional-constant:
digit-sequence . digit-sequence
digit-sequence .
digit-sequence

exponent-part:
e sign_opt digit-sequence
E sign_opt digit-sequence

sign: one of
+ –

digit-sequence:
digit
digit-sequence digit

floating-suffix: one of
f F

A decimal point (.) is not needed if the exponent part is present. No white space may appear anywhere within a floating-point constant, including before a suffix. A leading unary minus sign (-) is interpreted as a unary operator and is not part of the floating-point constant.

4.1.5 Vectors

The OpenGL Shading Language includes data types for generic 2-, 3-, and 4-component vectors of floating-point values, integers, or Booleans. Floating-point vector variables can be used to store a variety of things that are very useful in computer graphics: colors, normals, positions, texture coordinates, texture lookup results and the like. Boolean vectors can be used for component-wise comparisons of numeric vectors. Defining vectors as part of the shading language allows for direct mapping of vector operations on graphics hardware that is capable of doing vector processing. In general, applications will be able to take better advantage of the parallelism in graphics hardware by doing computations on vectors rather than on scalar values. Some examples of vector declaration are:

vec2 texcoord1, texcoord2;
vec3 position;
vec4 myRGBA;
ivec2 textureLookup;
bvec3 less;

Initialization of vectors can be done with constructors, which are discussed shortly.

4.1.6 Matrices

The OpenGL Shading Language has built-in types for 2×2, 2×3, 2×4, 3×2, 3×3, 3×4, 4×2, 4×3, and 4×4 matrices of floating-point numbers. The first number in the type is the number of columns, the second is the number of rows. Example matrix declarations:
4 Variables and Types

mat2 mat2D;
mat3 optMatrix;
mat4 view, projection;
mat4x4 view; // an alternate way of declaring a mat4
mat3x2 m;   // a matrix with 3 columns and 2 rows

Initialization of matrix values is done with constructors (described in Section 5.4 “Constructors”) in column-major order.

4.1.7 Samplers

Sampler types (e.g. sampler2D) are effectively opaque handles to textures and their filters. They are used with the built-in texture functions (described in Section 8.7 “Texture Lookup Functions”) to specify which texture to access and how it is to be filtered. They can only be declared as function parameters or uniform variables (see Section 4.3.5 “Uniform”). Except for array indexing, structure field selection, and parentheses, samplers are not allowed to be operands in expressions. Samplers aggregated into arrays within a shader (using square brackets []) can only be indexed with integral constant expressions (see Section 4.3.3 “Constant Expressions”). Samplers cannot be treated as l-values; hence cannot be used as out or inout function parameters, nor can they be assigned into. As uniforms, they are initialized only with the OpenGL API; they cannot be declared with an initializer in a shader. As function parameters, only samplers may be passed to samplers of matching type. This enables consistency checking between shader texture accesses and OpenGL texture state before a shader is run.

4.1.8 Structures

User-defined types can be created by aggregating other already defined types into a structure using the struct keyword. For example,

```
struct light {
  float intensity;
  vec3 position;
} lightVar;
```

In this example, light becomes the name of the new type, and lightVar becomes a variable of type light. To declare variables of the new type, use its name (without the keyword struct).

```
light lightVar2;
```

More formally, structures are declared as follows. However, the complete correct grammar is as given in Section 9 “Shading Language Grammar”.

```
struct-definition :
  qualifier_opt struct name_opt { member-list } declarators_opt;

member-list :
  member-declaration;
  member-declaration member-list;

member-declaration :
  basic-type declarators;
```
where name becomes the user-defined type, and can be used to declare variables to be of this new type. The name shares the same name space as other variables, types, and functions, with the same scoping rules. The optional qualifier only applies to any declarators, and is not part of the type being defined for name.

Structures must have at least one member declaration. Member declarators do not contain any qualifiers. Nor do they contain any bit fields. Member types must be already defined (there are no forward references). Member declarations cannot contain initializers. Member declarators can contain arrays. Such arrays must have a size specified, and the size must be an integral constant expression that’s greater than zero (see Section 4.3.3 “Constant Expressions”). Each level of structure has its own name space for names given in member declarators; such names need only be unique within that name space.

Anonymous structures are not supported. Embedded structure definitions are not supported.

```c
struct S { float f; }

struct T {
    S;          // Error: anonymous structures disallowed
    struct { ... }; // Error: embedded structures disallowed
    S s;        // Okay: nested structures with name are allowed
};
```

Structures can be initialized at declaration time using constructors, as discussed in Section 5.4.3 “Structure Constructors”.

### 4.1.9 Arrays

Variables of the same type can be aggregated into arrays by declaring a name followed by brackets ([]) enclosing an optional size. When an array size is specified in a declaration, it must be an integral constant expression (see Section 4.3.3 “Constant Expressions”) greater than zero. If an array is indexed with an expression that is not an integral constant expression, or if an array is passed as an argument to a function, then its size must be declared before any such use. It is legal to declare an array without a size and then later re-declare the same name as an array of the same type and specify a size. It is illegal to declare an array with a size, and then later (in the same shader) index the same array with an integral constant expression greater than or equal to the declared size. It is also illegal to index an array with a negative constant expression. Arrays declared as formal parameters in a function declaration must specify a size. Undefined behavior results from indexing an array with a non-constant expression that’s greater than or equal to the array’s size or less than 0. Only one-dimensional arrays may be declared. All basic types and structures can be formed into arrays. Some examples are:

```c
float frequencies[3];
uniform vec4 lightPosition[4];
light lights[];
const int numLights = 2;
light lights[numLights];
```

An array type can be formed by specifying a type followed by square brackets ([ ]) and including a size:

```c
float frequencies[3];
```
float[5]

This type can be used anywhere any other type can be used, including as the return value from a function

```c
float[5] foo() { }
```

as a constructor of an array

```c
float[5](3.4, 4.2, 5.0, 5.2, 1.1)
```

as an unnamed parameter

```c
void foo(float[5])
```

and as an alternate way of declaring a variable or function parameter.

```c
float[5] a;
```

It is an error to declare arrays of arrays:

```c
float a[5][3];  // illegal
float[5] a[3];  // illegal
```

Arrays can have initializers formed from array constructors:

```c
float a[5] = float[5](3.4, 4.2, 5.0, 5.2, 1.1);
float a[5] = float[](3.4, 4.2, 5.0, 5.2, 1.1);  // same thing
```

Unsized arrays can be explicitly sized by an initializer at declaration time:

```c
float a[5];
...
float b[] = a;  // b is explicitly size 5
float b[5] = a;  // means the same thing
```

However, implicitly sized arrays cannot be assigned to. Note, this is a rare case that initializers and assignments appear to have different semantics.

Arrays know the number of elements they contain. This can be obtained by using the length method:

```c
a.length();  // returns 5 for the above declarations
```

The length method cannot be called on an array that has not been explicitly sized.
4.1.10 Implicit Conversions

In some situations, an expression and its type will be implicitly converted to a different type. The following table shows all allowed implicit conversions:

<table>
<thead>
<tr>
<th>Type of expression</th>
<th>Can be implicitly converted to</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>float</td>
</tr>
<tr>
<td>uint</td>
<td></td>
</tr>
<tr>
<td>ivec2</td>
<td>vec2</td>
</tr>
<tr>
<td>uvec2</td>
<td></td>
</tr>
<tr>
<td>ivec3</td>
<td>vec3</td>
</tr>
<tr>
<td>uvec3</td>
<td></td>
</tr>
<tr>
<td>ivec4</td>
<td>vec4</td>
</tr>
<tr>
<td>uvec4</td>
<td></td>
</tr>
</tbody>
</table>

There are no implicit array or structure conversions. For example, an array of int cannot be implicitly converted to an array of float. There are no implicit conversions between signed and unsigned integers.

When an implicit conversion is done, it is not just a re-interpretation of the expression's bit pattern value, but a conversion of its value to an equivalent value in the new type. For example, the integer value 5 will be converted to the floating-point value 5.0. Integer values having more bits of precision than a floating point mantissa will lose precision when converted to float.

The conversions in the table above are done only as indicated by other sections of this specification.

4.2 Scoping

The scope of a variable is determined by where it is declared. If it is declared outside all function definitions, it has global scope, which starts from where it is declared and persists to the end of the shader it is declared in. If it is declared in a while test or a for statement, then it is scoped to the end of the following sub-statement. Otherwise, if it is declared as a statement within a compound statement, it is scoped to the end of that compound statement. If it is declared as a parameter in a function definition, it is scoped until the end of that function definition. A function body has a scope nested inside the function’s definition. The if statement’s expression does not allow new variables to be declared, hence does not form a new scope.

Within a declaration, the scope of a name starts immediately after the initializer if present or immediately after the name being declared if not. Several examples:
int x = 1;
{
    int x = 2, y = x; // y is initialized to 2
}

struct S
{
    int x;
};

{
    S s = S(0,0); // 'S' is only visible as a struct and constructor
    S;            // 'S' is now visible as a variable
}

int x = x; // Error if x has not been previously defined.

All variable names, structure type names, and function names in a given scope share the same name space. Function names can be redeclared in the same scope, with the same or different parameters, without error. An implicitly sized array can be re-declared in the same scope as an array of the same base type. Otherwise, within one compilation unit, a declared name cannot be redeclared in the same scope; doing so results in a redeclaration error. If a nested scope redeclares a name used in an outer scope, it hides all existing uses of that name. There is no way to access the hidden name or make it unhidden, without exiting the scope that hid it.

The built-in functions are scoped in a scope outside the global scope users declare global variables in. That is, a shader's global scope, available for user-defined functions and global variables, is nested inside the scope containing the built-in functions. When a function name is redeclared in a nested scope, it hides all functions declared with that name in the outer scope. Function declarations (prototypes) cannot occur inside of functions; they must be at global scope, or for the built-in functions, outside the global scope.

Shared globals are global variables declared with the same name in independently compiled units (shaders) of the same language (vertex or fragment) that are linked together to make a single program. Shared globals share the same name space, and must be declared with the same type. They will share the same storage. Shared global arrays must have the same base type and the same explicit size. An array implicitly sized in one shader can be explicitly sized by another shader. If no shader has an explicit size for the array, the largest implicit size is used. Scalars must have exactly the same type name and type definition. Structures must have the same name, sequence of type names, and type definitions, and field names to be considered the same type. This rule applies recursively for nested or embedded types. All initializers for a shared global must have the same value, or a link error will result.
4.3 Storage Qualifiers

Variable declarations may have a storage qualifier specified in front of the type. These are summarized as

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; none: default &gt;</td>
<td>local read/write memory, or an input parameter to a function</td>
</tr>
<tr>
<td>const</td>
<td>a compile-time constant, or a function parameter that is read-only</td>
</tr>
<tr>
<td>in centroid in</td>
<td>linkage into a shader from a previous stage, variable is copied in</td>
</tr>
<tr>
<td></td>
<td>linkage with centroid based interpolation</td>
</tr>
<tr>
<td>out centroid out</td>
<td>linkage out of a shader to a subsequent stage, variable is copied out</td>
</tr>
<tr>
<td></td>
<td>linkage with centroid based interpolation</td>
</tr>
<tr>
<td>attribute</td>
<td>deprecated: linkage between a vertex shader and OpenGL for per-vertex</td>
</tr>
<tr>
<td></td>
<td>data</td>
</tr>
<tr>
<td>uniform</td>
<td>value does not change across the primitive being processed, uniforms</td>
</tr>
<tr>
<td></td>
<td>form the linkage between a shader, OpenGL, and the application</td>
</tr>
<tr>
<td>varying</td>
<td>deprecated: linkage between a vertex shader and a fragment shader for</td>
</tr>
<tr>
<td>centroid varying</td>
<td>interpolated data</td>
</tr>
</tbody>
</table>

Outputs from a vertex shader (out) and inputs to a fragment shader (in) can be further qualified with one or more of these interpolation qualifiers

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>smooth</td>
<td>perspective correct interpolation</td>
</tr>
<tr>
<td>flat</td>
<td>no interpolation</td>
</tr>
<tr>
<td>noperspective</td>
<td>linear interpolation</td>
</tr>
</tbody>
</table>

These interpolation qualifiers may only precede the qualifiers in, centroid in, out, or centroid out in a declaration. They do not apply to the deprecated storage qualifiers varying or centroid varying. They also do not apply to inputs into a vertex shader or outputs from a fragment shader.

Global variables can only use the qualifiers const, attribute, uniform, varying, or centroid varying. Only one may be specified.

Local variables can only use the const storage qualifier.

Function parameters can only use the const, in, out, storage qualifiers, but as parameter qualifiers. Parameter qualifiers are discussed in more detail in Section 6.1.1 “Function Calling Conventions”.

Function return types and structure fields do not use storage qualifiers.

Data types for communication from one run of a shader executable to its next run (to communicate between fragments or between vertices) do not exist. This would prevent parallel execution of the same shader executable on multiple vertices or fragments.
4 Variables and Types

Initializers may only be used in declarations of globals with no storage qualifier, with a `const` qualifier; or with a `uniform` qualifier. Global variables without storage qualifiers that are not initialized in their declaration or by the application will not be initialized by OpenGL, but rather will enter `main()` with undefined values.

### 4.3.1 Default Storage Qualifier

If no qualifier is present on a global variable, then the variable has no linkage to the application or shaders running on other pipeline stages processors. For either global or local unqualified variables, the declaration will appear to allocate memory associated with the processor it targets. This variable will provide read/write access to this allocated memory.

### 4.3.2 Const

Named compile-time constants can be declared using the `const` qualifier. Any variables qualified as constant are read-only variables for that shader. Declaring variables as constant allows more descriptive shaders than using hard-wired numerical constants. The `const` qualifier can be used with any of the basic data types. It is an error to write to a `const` variable outside of its declaration, so they must be initialized when declared. For example,

```
const vec3 zAxis = vec3 (0.0, 0.0, 1.0);
```

Structure fields may not be qualified with `const`. Structure variables can be declared as `const`, and initialized with a structure constructor.

Initializers for const declarations must be constant expressions, as defined in Section 4.3.3 “Constant Expressions.”

### 4.3.3 Constant Expressions

A constant expression is one of

- a literal value (e.g., 5 or `true`)
- a global or local variable qualified as `const` (i.e. not including function parameters)
- an expression formed by an operator on operands that are all constant expressions, including getting an element or length of a constant array, or a field of a constant structure, or components of a constant vector.
- a constructor whose arguments are all constant expressions
- a built-in function call whose arguments are all constant expressions, with the exception of the texture lookup functions, the noise functions, and `ftransform`. The built-in functions `dFdx`, `dFdy`, and `fwidth` must return 0 when evaluated inside an initializer with an argument that is a constant expression.

Function calls to user-defined functions (non-built-in functions) cannot be used to form constant expressions.

An integral constant expression is a constant expression that evaluates to a scalar `signed` or `unsigned` integer.
Constant expressions will be evaluated in an invariant way so as to create the same value in multiple shaders when the same constant expressions appear in those shaders. See section 4.6.1 “The Invariant Qualifier” for more details on how to create invariant expressions.

4.3.4 Inputs

Shader input variables are declared with the in storage qualifier or the centroid in storage qualifier. They form the input interface between previous stages of the OpenGL pipeline and the declaring shader. Input variables must be declared at global scope. Values from the previous pipeline stage are copied into input variables at the beginning of shader execution. Variables declared as in or centroid in may not be written to during shader execution.

Vertex shader input variables (or attributes) receive per-vertex data. They are declared in a vertex shader with the in qualifier or the deprecated attribute qualifier. It is an error to use centroid in in a vertex shader. The values copied in are established by the OpenGL API. It is an error to use attribute in a non-vertex shader. Vertex shader inputs can only be float, floating-point vectors, matrices, signed and unsigned integers and integer vectors. They cannot be arrays or structures.

Example declarations in a vertex shader:

```
in vec4 position;
in vec3 normal;
in vec2 texCoord;
```

See Section 7 “Built-in Variables” for a list of the built-in input names.

Fragment shader inputs (or varyings) get per-fragment values, typically interpolated from a previous stage's outputs. They are declared in fragment shaders with the in storage qualifier, the centroid in storage qualifier, or the deprecated varying and centroid varying storage qualifiers. Fragment inputs can only be signed and unsigned integers and integer vectors, float, floating-point vectors, matrices, or arrays of these. Structures cannot be input.

Fragment inputs are declared as in the following examples:

```
in vec3 normal;
centroid in vec2 TexCoord;
invariant centroid in vec4 Color;
noperspective out float temperature;
flat in vec3 myColor;
centroid noperspective in vec2 myTexCoord;
```

The attribute qualifier is used to declare variables that are passed to a vertex shader from OpenGL on a per-vertex basis. It is an error to declare an attribute variable in any type of shader other than a vertex shader. Attribute variables are read only as far as the vertex shader is concerned. Values for attribute variables are passed to a vertex shader through the OpenGL vertex API or as part of a vertex array. They convey vertex attributes to the vertex shader and are expected to change on every vertex shader run. The attribute qualifier can be used only with float, floating-point vectors, and matrices. Attribute variables cannot be declared as arrays or structures.
4 Variables and Types

Example declarations:

attribute vec4 position;
attribute vec3 normal;
attribute vec2 texCoord;

All the standard OpenGL vertex attributes have built-in variable names to allow easy integration between user programs and OpenGL vertex functions. See Section 7 “Built-in Variables” for a list of the built-in attribute names.

It is expected that graphics hardware will have a small number of fixed vector locations for passing vertex attributes inputs. Therefore, the OpenGL Shading language defines each non-matrix input attribute variable as taking up one such vector location having space for up to four floating-point values (i.e., a vec4). There is an implementation dependent limit on the number of locations attribute variables that can be used, and if this is exceeded it will cause a link error. (Declared attribute input variables that are not statically used do not count against this limit.) A float attribute scalar input counts the same amount against this limit as a vec4, so applications may want to consider packing groups of four unrelated float attributes inputs together into a vec4 vector to better utilize the capabilities of the underlying hardware. A matrix attribute input will use up multiple attribute locations. The number of locations used will equal the number of columns in the matrix.

Attribute variables are required to have global scope, and must be declared outside of function bodies, before their first use.

4.3.5 Uniform

The uniform qualifier is used to declare global variables whose values are the same across the entire primitive being processed. All uniform variables are read-only and are initialized externally either at link time or through the API. The link time initial value is either the value of the variable's initializer, if present, or 0 if no initializer is present. Sampler types cannot have initializers.

Example declarations are:

uniform vec4 lightPosition;
uniform vec3 color = vec3(0.7, 0.7, 0.2); // value assigned at link time

The uniform qualifier can be used with any of the basic data types, or when declaring a variable whose type is a structure, or an array of any of these.

There is an implementation dependent limit on the amount of storage for uniforms that can be used for each type of shader and if this is exceeded it will cause a compile-time or link-time error. Uniform variables that are declared but not used do not count against this limit. The number of user-defined uniform variables and the number of built-in uniform variables that are used within a shader are added together to determine whether available uniform storage has been exceeded. If multiple shaders are linked together, then they will share a single global uniform name space. Hence, the types and initializers of uniform variables with the same name must match across all shaders that are linked into a single executable. It is legal for some shaders to provide an initializer for a particular uniform variable, while another shader does not, but all provided initializers must be equal.
4.3.6 Outputs

Shader output variables are declared with the **out** or **centroid out** storage qualifiers. They form the output interface between the declaring shader and the subsequent stages of the OpenGL pipeline. Output variables must be declared at global scope. During shader execution they will behave as normal unqualified global variables. Their values are copied out to the subsequent pipeline stage on shader exit.

There is not an **inout** storage qualifier at global scope for declaring a single variable name as both input and output to a shader. Output variables must be declared with different names than input variables.

By definition, varying variables are set per vertex and are interpolated in a perspective-correction manner over the primitive being rendered.

Vertex shaders will compute values per vertex (such as color, texture coordinates, etc.) and write them to variables declared with the **varying** qualifier.

Vertex output variables output per-vertex data and are declared using the **out** storage qualifier, the **centroid out** storage qualifier, or the deprecated **varying** storage qualifier. They can only be float, floating-point vectors, matrices, signed or unsigned integers or integer vectors, or arrays of any these. If a vertex output is a signed or unsigned integer or integer vector, then it must be qualified with the interpolation qualifier **flat**. Structures cannot be output.

Vertex outputs are declared as in the following examples:

```glsl
out vec3 normal;
centroid out vec2 TexCoord;
invariant centroid out vec4 Color;
 noperspective out float temperature; // varying is deprecated
flat out vec3 myColor;
noperspective centroid out vec2 myTexCoord;
```

Fragment outputs output per-fragment data and are declared using the **out** storage qualifier. It is an error to use **centroid** in a fragment shader. Fragment outputs can only be float, floating-point vectors, signed or unsigned integers or integer vectors, or arrays of any these. Matrices and structures cannot be output. Fragment outputs are declared as in the following examples:

```glsl
out vec4 FragmentColor;
out uint Luminosity;
```

A vertex shader may also read varying variables, getting back the same values it has written. Reading a varying variable in a vertex shader returns undefined values if it is read before being written.

The varying qualifier can be used only with float, floating-point vectors, matrices, or arrays of these. Structures cannot be varying.

Varying variables are required to have global scope, and must be declared outside of function bodies, before their first use.

4.3.7
A fragment shader may read from varying variables and the value read will be the interpolated value, as a function of the fragment’s position within the primitive. A fragment shader can not write to a varying variable.

The varying qualifier can be used only with float, floating point vectors, matrices, or arrays of these. Structures cannot be varying.

Varying variables are required to have global scope, and must be declared outside of function bodies, before their first use.

### 4.3.8 Interpolation

The presence of and type of interpolation is controlled by the storage qualifiers **centroid in** and **centroid out**, and by the optional interpolation qualifiers **smooth**, **flat**, and **noperspective** as well as by default behaviors established through the OpenGL API when no interpolation qualifier is present. When an interpolation qualifier is used, it overrides settings established through the OpenGL API. It is a compile-time error to use more than one interpolation qualifier.

The following predeclared variables can be redeclared with an interpolation qualifier:

**Vertex language:**
- `gl_FrontColor`
- `gl_BackColor`
- `gl_FrontSecondaryColor`
- `gl_BackSecondaryColor`

**Fragment language:**
- `gl_Color`
- `gl_SecondaryColor`

For example,

```glsl
in vec4 gl_Color;       // predeclared by the fragment language
flat in vec4 gl_Color;  // redeclared by user to be flat
```

If `gl_Color` is redeclared with an interpolation qualifier, then `gl_FrontColor` and `gl_BackColor` (if they are written to) must also be redeclared with the same interpolation qualifier, and vice versa. If `gl_SecondaryColor` is redeclared with an interpolation qualifier, then `gl_FrontSecondaryColor` and `gl_BackSecondaryColor` (if they are written to) must also be redeclared with the same interpolation qualifier, and vice versa. This qualifier matching on predeclared variables is only required for variables that are statically used within the shaders in a program.

A variable qualified as **flat** will not be interpolated. Instead, it will have the same value for every fragment within a triangle. This value will come from a single provoking vertex, as described by the OpenGL Graphics System Specification. User-declared variables can be qualified as **flat** and the predeclared variables listed above and can be redeclared as **flat**. It is an error to declare any other built-in variable as **flat**. A variable may be qualified as **flat centroid**, which will mean the same thing as qualifying it only as **flat**.
A variable qualified as **smooth** will be interpolated in a perspective-correct manner over the primitive being rendered. Interpolation in a perspective correct manner is specified in equations 3.6 and 3.8 in the OpenGL Graphics System Specification, Version 3.0.

A variable qualified as **noperspective** must be interpolated linearly in screen space, as described in equation 3.7 and the approximation that follows equation 3.8 in the OpenGL Graphics System Specification, Version 3.0.

This paragraph only applies if interpolation is being done: If single-sampling, the value is interpolated to the pixel's center, and the **centroid** qualifier, if present, is ignored. If multi-sampling and the variable is not qualified with **centroid**, then the value must be interpolated to the pixel's center, or anywhere within the pixel, or to one of the pixel's samples. If multi-sampling and varying the variable is qualified with **centroid**, then the value must be interpolated to a point that lies in both the pixel and in the primitive being rendered, or to one of the pixel's samples that falls within the primitive. Due to the less regular location of centroids, their derivatives may be less accurate than non-centroid varying interpolated variables.

The type and presence of the interpolation qualifiers and storage qualifiers **centroid** and **invariant** of varying-variables with the same name declared in linked vertex and fragments shaders must match, otherwise the link command will fail. Only those varying variables used (i.e. read) **input variables read** in the fragment shader executable must be written to by the vertex shader executable; declaring superfluous varying **output** variables in a vertex shader is permissible.

Varying variables are declared as in the following examples:

```
    varying vec3 normal;
    centroid varying vec2 TexCoord;
    invariant centroid varying vec4 Color;
```

If no vertex shader executable is active, the fixed functionality pipeline of OpenGL will compute values for the built-in varying variables that will be consumed by the fragment shader executable. Similarly, if no fragment shader executable is active, the vertex shader executable is responsible for computing and writing to the varying variables that are needed for OpenGL’s fixed functionality fragment pipeline.

### 4.4 Parameter Qualifiers

Parameters can have these qualifiers.

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; none: default &gt;</td>
<td>same is <strong>in</strong></td>
</tr>
<tr>
<td><strong>in</strong></td>
<td>for function parameters passed into a function</td>
</tr>
<tr>
<td><strong>out</strong></td>
<td>for function parameters passed back out of a function, but not initialized for use when passed in</td>
</tr>
<tr>
<td><strong>inout</strong></td>
<td>for function parameters passed both into and out of a function</td>
</tr>
</tbody>
</table>
Parameter qualifiers are discussed in more detail in Section 6.1.1 “Function Calling Conventions”.

### 4.5 Precision and Precision Qualifiers

Section number reserved for precision qualifiers. (Reserved for future use.)

Precision qualifiers are added for code portability with OpenGL ES, not for functionality. They have the same syntax as in OpenGL ES, as described below, but they have no semantic meaning, which includes no effect on the precision used to store or operate on variables.

If an extension adds in the same semantics and functionality in the OpenGL ES 2.0 specification for precision qualifiers, then the extension is allowed to reuse the keywords below for that purpose.

### 4.5.1 Range and Precision

Section number reserved for future use.

### 4.5.2 Precision Qualifiers

Any floating point or any integer declaration can have the type preceded by one of these precision qualifiers:

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>highp</td>
<td>None.</td>
</tr>
<tr>
<td>mediump</td>
<td>None.</td>
</tr>
<tr>
<td>lowp</td>
<td>None.</td>
</tr>
</tbody>
</table>

For example:

```glsl
lowp float color;
out mediump vec2 P;
lowp ivec2 foo(lowp mat3);
highp mat4 m;
```

Literal constants do not have precision qualifiers. Neither do Boolean variables. Neither do floating point constructors nor integer constructors when none of the constructor arguments have precision qualifiers.

Precision qualifiers, as with other qualifiers, do not effect the basic type of the variable. In particular, there are no constructors for precision conversions; constructors only convert types. Similarly, precision qualifiers, as with other qualifiers, do not contribute to function overloading based on parameter types. As discussed in the next chapter, function input and output is done through copies, and therefore qualifiers do not have to match.

The same object declared in different shaders that are linked together must have the same precision qualification. This applies to inputs, outputs, uniforms, and globals.
4.5.3 Default Precision Qualifiers

The precision statement

```cpp
precision precision-qualifier type;
```

can be used to establish a default precision qualifier. The type field can be either int or float, and the precision-qualifier can be lowp, mediump, or highp. Any other types or qualifiers will result in an error. If type is float, the directive applies to non-precision-qualified floating point type (scalar, vector, and matrix) declarations. If type is int, the directive applies to all non-precision-qualified integer type (scalar, vector, signed, and unsigned) declarations. This includes global variable declarations, function return declarations, function parameter declarations, and local variable declarations.

Non-precision qualified declarations will use the precision qualifier specified in the most recent precision statement that is still in scope. The precision statement has the same scoping rules as variable declarations. If it is declared inside a compound statement, its effect stops at the end of the innermost statement it was declared in. Precision statements in nested scopes override precision statements in outer scopes. Multiple precision statements for the same basic type can appear inside the same scope, with later statements overriding earlier statements within that scope.

The vertex language has the following predeclared globally scoped default precision statements:

```cpp
precision highp float;
precision highp int;
```

The fragment language has the following predeclared globally scoped default precision statement:

```cpp
precision mediump int;
```

The fragment language has no default precision qualifier for floating point types. Hence for float, floating point vector and matrix variable declarations, either the declaration must include a precision qualifier or the default float precision must have been previously declared.

4.5.4 Available Precision Qualifiers

The built-in macro GL_FRAGMENT_PRECISION_HIGH is defined to 1:

```cpp
#define GL_FRAGMENT_PRECISION_HIGH 1
```

This macro is available in both the vertex and fragment languages.

4.6 Variance and the Invariant Qualifier

In this section, variance refers to the possibility of getting different values from the same expression in different programs. For example, say two vertex shaders, in different programs, each set gl_Position with the same expression in both shaders, and the input values into that expression are the same when both shaders run. It is possible, due to independent compilation of the two shaders, that the values assigned to gl_Position are not exactly the same when the two shaders run. In this example, this can cause problems with alignment of geometry in a multi-pass algorithm.

In general, such variance between shaders is allowed. When such variance does not exist for a particular output variable, that variable is said to be invariant.
4.6.1 The Invariant Qualifier

To ensure that a particular output variable is invariant, it is necessary to use the `invariant` qualifier. It can either be used to qualify a previously declared variable as being invariant

```glsl
invariant gl_Position;  // make existing gl_Position be invariant

varying out vec3 Color;
invariant Color;         // make existing Color be invariant
```

or as part of a declaration when a variable is declared

```glsl
invariant varying centroid out vec3 Color;
```

The invariant qualifier must appear before any interpolation qualifiers or storage qualifiers (`varying`) when combined with a declaration. Only variables output from a vertex shader can be candidates for invariance. This includes user-defined `varying output` variables and the built-in vertex side `varying output` variables, and the special vertex variables `gl_Position` and `glPointSize`. For varying variables leaving a vertex shader and coming into a fragment shader with the same name, the `invariant` keyword has to be used in both the vertex and fragment shaders.

The `invariant` keyword can be followed by a comma separated list of previously declared identifiers. All uses of `invariant` must be at the global scope, and before any use of the variables being declared as invariant.

To guarantee invariance of a particular output variable across two programs, the following must also be true:

- The output variable is declared as invariant in both programs.
- The same values must be input to all shader input variables consumed by expressions and flow control contributing to the value assigned to the output variable.
- The texture formats, texel values, and texture filtering are set the same way for any texture function calls contributing to the value of the output variable.
- All input values are all operated on in the same way. All operations in the consuming expressions and any intermediate expressions must be the same, with the same order of operands and same associativity, to give the same order of evaluation. Intermediate variables and functions must be declared as the same type with the same explicit or implicit precision qualifiers. Any control flow affecting the output value must be the same, and any expressions consumed to determine this control flow must also follow these invariance rules.
- All the data flow and control flow leading to setting the invariant output variable reside in a single compilation unit.

Essentially, all the data flow and control flow leading to an invariant output must match.

Initially, by default, all output variables are allowed to be variant. To force all output variables to be invariant, use the pragma
#pragma STDGL invariant(all)

before all declarations in a shader. If this pragma is used after the declaration of any variables or functions, then the set of outputs that behave as invariant is undefined. It is an error to use this pragma in a fragment shader.

Generally, invariance is ensured at the cost of flexibility in optimization, so performance can be degraded by use of invariance. Hence, use of this pragma is intended as a debug aid, to avoid individually declaring all output variables as invariant.

## 4.6.2 Invariance of Constant Expressions

Invariance must be guaranteed for constant expressions. A particular constant expression must evaluate to the same result if it appears again in the same shader or a different shader. This includes the same expression appearing in both a vertex and fragment shader or the same expression appearing in different vertex or fragment shaders.

Constant expressions must evaluate to the same result when operated on as already described above for invariant variables.

## 4.7 Order of Qualification

When multiple qualifications are present, they must follow a strict order. This order is as follows.

- `invariant-qualifier`
- `interpolation-qualifier`
- `storage-qualifier`
- `precision qualifier`

- `storage-qualifier`
- `parameter-qualifier`
- `precision qualifier`
# 5 Operators and Expressions

## 5.1 Operators

The OpenGL Shading Language has the following operators. **Those marked reserved are illegal.**

<table>
<thead>
<tr>
<th>Precedence</th>
<th>Operator Class</th>
<th>Operators</th>
<th>Associativity</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (highest)</td>
<td>parenthetical grouping</td>
<td>( )</td>
<td>NA</td>
</tr>
<tr>
<td>2</td>
<td>array subscript function call and constructor structure field or method selector, swizzler post fix increment and decrement</td>
<td>[ ] ( ) . ++ --</td>
<td>Left to Right</td>
</tr>
<tr>
<td>3</td>
<td>prefix increment and decrement unary (tilde is reserved)</td>
<td>++ -- + - ~ !</td>
<td>Right to Left</td>
</tr>
<tr>
<td>4</td>
<td>multiplicative (modulus reserved)</td>
<td>* / %</td>
<td>Left to Right</td>
</tr>
<tr>
<td>5</td>
<td>additive</td>
<td>+ -</td>
<td>Left to Right</td>
</tr>
<tr>
<td>6</td>
<td>bit-wise shift-(reserved)</td>

<tr>
<td>17 (lowest)</td>
<td>sequence</td>
<td>,</td>
<td>Left to Right</td>
</tr>
</tbody>
</table>

There is no address-of operator nor a dereference operator. There is no typecast operator, constructors are used instead.
5.2 **Array Operations**
These are now described in Section 5.7 “Structure and Array Operations”.

5.3 **Function Calls**
If a function returns a value, then a call to that function may be used as an expression, whose type will be the type that was used to declare or define the function.

Function definitions and calling conventions are discussed in Section 6.1 “Function Definitions”.

5.4 **Constructors**
Constructors use the function call syntax, where the function name is a type, and the call makes an object of that type. Constructors are used the same way in both initializers and expressions. (See Section 9 “Shading Language Grammar” for details.) The parameters are used to initialize the constructed value. Constructors can be used to request a data type conversion to change from one scalar type to another scalar type, or to build larger types out of smaller types, or to reduce a larger type to a smaller type.

In general, constructors are not built-in functions with predetermined prototypes. For arrays and structures, there must be exactly one argument in the constructor for each element or field. For the other types, the arguments must provide a sufficient number of components to perform the initialization, and it is an error to include so many arguments that they cannot all be used. Detailed rules follow. The prototypes actually listed below are merely a subset of examples.

5.4.1 **Conversion and Scalar Constructors**
Converting between scalar types is done as the following prototypes indicate:

```plaintext
int(bool) // converts a Boolean value to an int
int(float) // converts a float value to an int
float(bool) // converts a Boolean value to a float
float(int) // converts an unsigned integer value to a float
bool(float) // converts a float value to a Boolean
bool(int) // converts an unsigned integer value to a Boolean
uint(bool) // converts a Boolean value to an unsigned integer
uint(float) // converts a float value to an unsigned integer
uint(int) // converts an unsigned integer value to an unsigned integer
int(uint) // converts an unsigned integer value to a signed integer
bool(uint) // converts an unsigned integer value to a Boolean value
float(uint) // converts an unsigned integer value to a float value
```

When constructors are used to convert a `float` to an `int` or `uint`, the fractional part of the floating-point value is dropped. **It is undefined to convert a negative floating point value to an uint.**

When a constructor is used to convert an `int`, `uint`, or a `float` to a `bool`, 0 and 0.0 are converted to `false`, and non-zero values are converted to `true`. When a constructor is used to convert a `bool` to an `int`, `uint`, or `float`, `false` is converted to 0 or 0.0, and `true` is converted to 1 or 1.0.
The constructor `int(uint)` preserves the bit pattern in the argument, which will change the argument’s value if its sign bit is set. The constructor `uint(int)` preserves the bit pattern in the argument, which will change its value if it is negative.

Identity constructors, like `float(float)` are also legal, but of little use.

Scalar constructors with non-scalar parameters can be used to take the first element from a non-scalar. For example, the constructor `float(vec3)` will select the first component of the `vec3` parameter.

### 5.4.2 Vector and Matrix Constructors

Constructors can be used to create vectors or matrices from a set of scalars, vectors, or matrices. This includes the ability to shorten vectors.

If there is a single scalar parameter to a vector constructor, it is used to initialize all components of the constructed vector to that scalar’s value. If there is a single scalar parameter to a matrix constructor, it is used to initialize all the components on the matrix’s diagonal, with the remaining components initialized to 0.0.

If a vector is constructed from multiple scalars, one or more vectors, or one or more matrices, or a mixture of these, the vectors’ components will be constructed in order from the components of the arguments. The arguments will be consumed left to right, and each argument will have all its components consumed, in order, before any components from the next argument are consumed. Similarly for constructing a matrix from multiple scalars or vectors, or a mixture of these. Matrix components will be constructed and consumed in column-major order. In these cases, there must be enough components provided in the arguments to provide an initializer for every component in the constructed value. It is an error to provide extra arguments beyond this last used argument.

If a matrix is constructed from a matrix, then each component (column $i$, row $j$) in the result that has a corresponding component (column $i$, row $j$) in the argument will be initialized from there. All other components will be initialized to the identity matrix. If a matrix argument is given to a matrix constructor, it is an error to have any other arguments.

If the basic type (`bool`, `int`, or `float`) of a parameter to a constructor does not match the basic type of the object being constructed, the scalar construction rules (above) are used to convert the parameters.

Some useful vector constructors are as follows:
vec3(float)  // initializes each component of with the float
vec4(ivec4)  // makes a vec4 with component-wise conversion
vec4(mat2)   // the vec4 is column 0 followed by column 1

vec2(float, float) // initializes a vec2 with 2 floats
ivec3(int, int, int) // initializes an ivec3 with 3 ints
bvec4(int, int, float, float) // uses 4 Boolean conversions

vec2(vec3)    // drops the third component of a vec3
vec3(vec4)    // drops the fourth component of a vec4

vec3(vec2, float) // vec3.x = vec2.x, vec3.y = vec2.y, vec3.z = float
vec3(float, vec2) // vec3.x = float, vec3.y = vec2.x, vec3.z = vec2.y
vec4(vec3, float)
vec4(float, vec3)
vec4(vec2, vec2)

Some examples of these are:

vec4 color = vec4(0.0, 1.0, 0.0, 1.0);
vec4 rgba  = vec4(1.0);  // sets each component to 1.0
vec3 rgb   = vec3(color); // drop the 4th component

To initialize the diagonal of a matrix with all other elements set to zero:

mat2(float)
mat3(float)
mat4(float)

That is, result[i][j] is set to the float argument for all i = j and set to 0 for all i ≠ j.

To initialize a matrix by specifying vectors or scalars, the components are assigned to the matrix elements in column-major order.
5 Operators and Expressions

mat2(vec2, vec2);             // one column per argument
mat3(vec3, vec3, vec3);       // one column per argument
mat4(vec4, vec4, vec4, vec4); // one column per argument
mat3x2(vec2, vec2, vec2);     // one column per argument
mat2(float, float, float, float); // first column
                        // second column
mat3(float, float, float, float, float, float); // first column
                        // second column
                        // third column
mat4(float, float, float, float, float, float, float, float); // first column
                        // second column
                        // third column
                        // fourth column
mat2x3(vec2, float, vec2, float); // first column
                        // second column

A wide range of other possibilities exist, to construct a matrix from vectors and scalars, as long as enough components are present to initialize the matrix. To construct a matrix from a matrix:

mat3x3(mat4x4);  // takes the upper-left 3x3 of the mat4x4
mat2x3(mat4x2);  // takes the upper-left 2x2 of the mat4x4, last row is 0,0
mat4x4(mat3x3);  // puts the mat3x3 in the upper-left, sets the lower right
                        // component to 1, and the rest to 0

5.4.3 Structure Constructors

Once a structure is defined, and its type is given a name, a constructor is available with the same name to construct instances of that structure. For example:

struct light {
    float intensity;
    vec3 position;
};

light lightVar = light(3.0, vec3(1.0, 2.0, 3.0));

The arguments to the constructor will be used to set the structure's fields, in order, using one argument per field. Each argument must be the same type as the field it sets, or be a type that can be converted to the field's type according to Section 4.1.10 “Implicit Conversions.”

Structure constructors can be used as initializers or in expressions.

5.4.4 Array Constructors

Array types can also be used as constructor names, which can then be used in expressions or initializers. For example,
const float c[3] = float[3](5.0, 7.2, 1.1);
const float d[3] = float[]{}(5.0, 7.2, 1.1);

float g;
...
float a[5] = float[5](g, 1, g, 2.3, g);
float b[3];
    b = float[3](g, g + 1.0, g + 2.0);

There must be exactly the same number of arguments as the size of the array being constructed. If no size is present in the constructor, then the array is explicitly sized to the number of arguments provided. The arguments are assigned in order, starting at element 0, to the elements of the constructed array. Each argument must be the same type as the element type of the array, or be a type that can be converted to the element type of the array according to Section 4.1.10 “Implicit Conversions.”

5.5 Vector Components

The names of the components of a vector are denoted by a single letter. As a notational convenience, several letters are associated with each component based on common usage of position, color or texture coordinate vectors. The individual components of a vector can be selected by following the variable name with period (.) and then the component name.

The component names supported are:

| {x, y, z, w} | Useful when accessing vectors that represent points or normals |
| {r, g, b, a} | Useful when accessing vectors that represent colors |
| {s, t, p, q} | Useful when accessing vectors that represent texture coordinates |

The component names x, r, and s are, for example, synonyms for the same (first) component in a vector.

Note that the third component of the texture coordinate set a texture, r in OpenGL, has been renamed p so as to avoid the confusion with r (for red) in a color.

Accessing components beyond those declared for the vector type is an error so, for example:

vec2 pos;
pos.x // is legal
pos.z // is illegal
The component selection syntax allows multiple components to be selected by appending their names (from the same name set) after the period (.)

```
vec4 v4;
v4.rgba; // is a vec4 and the same as just using v4,
v4.rgb;  // is a vec3,
v4.b;    // is a float,
v4.xy;   // is a vec2,
v4.xgba; // is illegal - the component names do not come from
          // the same set.
```

The order of the components can be different to swizzle them, or replicated:

```
vec4 pos = vec4(1.0, 2.0, 3.0, 4.0);
vec4 swiz = pos.wzyx; // swiz = (4.0, 3.0, 2.0, 1.0)
vec4 dup = pos.xxyy; // dup = (1.0, 1.0, 2.0, 2.0)
```

This notation is more concise than the constructor syntax. To form an r-value, it can be applied to any expression that results in a vector r-value.

The component group notation can occur on the left hand side of an expression.

```
vec4 pos = vec4(1.0, 2.0, 3.0, 4.0);
pos.xw = vec2(5.0, 6.0); // pos = (5.0, 2.0, 3.0, 6.0)
pos.wx = vec2(7.0, 8.0); // pos = (8.0, 2.0, 3.0, 7.0)
pos.xx = vec2(3.0, 4.0); // illegal - 'x' used twice
pos.xy = vec3(1.0, 2.0, 3.0); // illegal - mismatch between vec2 and vec3
```

To form an l-value, swizzling must be applied to an l-value of vector type, contain no duplicate components, and it results in an l-value of scalar or vector type, depending on number of components specified.

Array subscripting syntax can also be applied to vectors to provide numeric indexing. So in

```
vec4 pos;
pos[2] refers to the third element of pos and is equivalent to pos.z. This allows variable indexing into a
vector, as well as a generic way of accessing components. Any integer expression can be used as the
subscript. The first component is at index zero. Reading from or writing to a vector using a constant
integral expression with a value that is negative or greater than or equal to the size of the vector is illegal.
When indexing with non-constant expressions, behavior is undefined if the index is negative, or greater
than or equal to the size of the vector.

5.6 Matrix Components

The components of a matrix can be accessed using array subscripting syntax. Applying a single subscript
to a matrix treats the matrix as an array of column vectors, and selects a single column, whose type is a
vector of the same size as the matrix. The leftmost column is column 0. A second subscript would then
operate on the column resulting vector, as defined earlier for vectors. Hence, two subscripts select a
column and then a row.
mat4 m;
m[1] = vec4(2.0);        // sets the second column to all 2.0
m[0][0] = 1.0;           // sets the upper left element to 1.0
m[2][3] = 2.0;           // sets the 4th element of the third column to 2.0

Behavior is undefined when accessing a component outside the bounds of a matrix with a non-constant expression. It is an error to access a matrix with a constant expression that is outside the bounds of the matrix.

5.7 Structure and Array Operations

The fields of a structure and the length method of an array are selected using the period (.).

In total, only the following operators are allowed to operate on arrays and structures as whole entities:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field or method selector</td>
<td>.</td>
</tr>
<tr>
<td>equality</td>
<td>==  !=</td>
</tr>
<tr>
<td>assignment</td>
<td>=</td>
</tr>
<tr>
<td>indexing (arrays only)</td>
<td>[ ]</td>
</tr>
</tbody>
</table>

The equality operators and assignment operator are only allowed if the two operands are same size and type. Structure types must be of the same declared structure. Both array operands must be explicitly sized. When using the equality operators, two structures are equal if and only if all the fields are component-wise equal, and two arrays are equal if and only if all the elements are element-wise equal.

Array elements are accessed using the array subscript operator ( [ ] ). An example of accessing an array element is

```cpp
diffuseColor += lightIntensity[3] * NdotL;
```

Array indices start at zero. Array elements are accessed using an expression whose type is int or uint. Behavior is undefined if a shader subscripts an array with an index less than 0 or greater than or equal to the size the array was declared with.

Arrays can also be accessed with the method operator ( . ) and the length method to query the size of the array:

```cpp
lightIntensity.length()    // return the size of the array
```

5.8 Assignments

Assignments of values to variable names are done with the assignment operator ( = ) like

```cpp
lvalue-expression = rvalue-expression
```
The \textit{lvalue-expression} evaluates to an \textit{l-value}. The assignment operator stores the value of \textit{rvalue-expression} into \textit{lvalue} the \textit{l-value} and returns an \textit{r-value} with the type and precision of \textit{lvalue-expression}. The \textit{lvalue-expression} and \textit{rvalue-expression} must have the same type, or the expression must have a type in the table in Section 4.1.10 “Implicit Conversions” that converts to the type of \textit{lvalue-expression}, in which case an implicit conversion will be done on the expression \textit{rvalue-expression} before the assignment is done. Any other desired type-conversions must be specified explicitly via a constructor. \textit{l-values} must be writable. Variables that are built-in types, entire structures or arrays, structure fields, \textit{l-values} with the field selector (.) applied to select components or swizzles without repeated fields, \textit{l-values} within parentheses, and \textit{l-values} dereferenced with the array subscript operator ([ ] ) are all \textit{l-values}. Other binary or unary expressions, function names, swizzles with repeated fields, and constants cannot be \textit{l-values}. The ternary operator (?:) is also not allowed as an \textit{l-value}.

Expressions on the left of an assignment are evaluated before expressions on the right of the assignment. Other assignment operators are

The arithmetic assignments add into (+=), subtract from (-=), multiply into (*=), and divide into (/=), modulus into (%=), left shift by (<<=), right shift by (>>=), and into (&=), inclusive-or into (|=), and exclusive-or into (^=). The expression

\begin{verbatim}
lvalue op= expression
\end{verbatim}

is equivalent to

\begin{verbatim}
lvalue = lvalue op expression
\end{verbatim}

and the \textit{l-value} and expression must satisfy the semantic requirements of both \textit{op} and equals (=).

- The assignments modulus into (%=), left shift by (<<=), right shift by (>>=), inclusive or into (|=), and exclusive or into (^=) are reserved for future use.

Reading a variable before writing (or initializing) it is legal, however the value is undefined.

\section*{5.9 Expressions}

Expressions in the shading language are built from the following:

- Constants of type \texttt{bool}, \texttt{int}, \texttt{uint}, \texttt{float}, all vector types, and all matrix types.
- Constructors of all types.
- Variable names of all types.
- An array name with the length method applied.
- Subscripted array names.
- Function calls that return values.
- Component field selectors and array subscript results.
- Parenthesized expression. Any expression can be parenthesized. Parentheses can be used to group operations. Operations within parentheses are done before operations across parentheses.
The arithmetic binary operators add (+), subtract (-), multiply (*), and divide (/) operate on integer and floating-point scalars, vectors, and matrices. If one operand is floating-point based and the other is not, then the conversions from Section 4.1.10 “Implicit Conversions” are applied to the non-floating-point-based operand. If the operands are integer types, they must both be signed or both be unsigned. All arithmetic binary operators result in the same fundamental type (signed integer, unsigned integer, or floating-point) as the operands they operate on, after operand type conversion. After conversion, the following cases are valid:

- The two operands are scalars. In this case the operation is applied, resulting in a scalar.
- One operand is a scalar, and the other is a vector or matrix. In this case, the scalar operation is applied independently to each component of the vector or matrix, resulting in the same size vector or matrix.
- The two operands are vectors of the same size. In this case, the operation is done component-wise resulting in the same size vector.
- The operator is add (+), subtract (-), or divide (/), and the operands are matrices with the same number of rows and the same number of columns. In this case, the operation is done component-wise resulting in the same size matrix.
- The operator is multiply (*), where both operands are matrices or one operand is a vector and the other a matrix. A right vector operand is treated as a column vector and a left vector operand as a row vector. In all these cases, it is required that the number of columns of the left operand is equal to the number of rows of the right operand. Then, the multiply (*) operation does a linear algebraic multiply, yielding an object that has the same number of rows as the left operand and the same number of columns as the right operand. Section 5.10 “Vector and Matrix Operations” explains in more detail how vectors and matrices are operated on.

All other cases are illegal.

Dividing by zero does not cause an exception but does result in an unspecified value. Use the built-in functions dot, cross, matrixCompMult, and outerProduct, to get, respectively, vector dot product, vector cross product, matrix component-wise multiplication, and the matrix product of a column vector times a row vector.

- The operator modulus (%) is reserved for future use. Operates on signed or unsigned integers or integer vectors. The operand types must both be signed or both be unsigned. The operands cannot be vectors of differing size. If one operand is a scalar and the other vector, then the scalar is applied component-wise to the vector, resulting in the same type as the vector. If both are vectors of the same size, the result is computed component-wise. The resulting value is undefined for any component computed with a second operand that is zero, while results for other components with non-zero second operands remain defined. If both operands are non-negative, then the remainder is non-negative. Results are undefined if one or both operands are negative. The operator modulus (%) is not defined for any other data types (non-integer types).
5 Operators and Expressions

- The arithmetic unary operators negate (-), post- and pre-increment and decrement (\(--\) and \(++\)) operate on integer or floating-point values (including vectors and matrices). All unary operators work component-wise on their operands. These result with the same type they operated on. For post- and pre-increment and decrement, the expression must be one that could be assigned to (an l-value). Pre-increment and pre-decrement add or subtract 1 or 1.0 to the contents of the expression they operate on, and the value of the pre-increment or pre-decrement expression is the resulting value of that modification. Post-increment and post-decrement expressions add or subtract 1 or 1.0 to the contents of the expression they operate on, but the resulting expression has the expression’s value before the post-increment or post-decrement was executed.

- The relational operators greater than (\(>\)), less than (\(<\)), greater than or equal (\(\geq\)), and less than or equal (\(\leq\)) operate only on scalar integer and scalar floating-point expressions. The result is scalar Boolean. Either the operands’ types must match, or the conversions from Section 4.1.10 “Implicit Conversions” will be applied to the integer operand, after which the types must match. To do component-wise relational comparisons on vectors, use the built-in functions \texttt{lessThan}, \texttt{lessThanEqual}, \texttt{greaterThan}, and \texttt{greaterThanEqual}.

- The equality operators equal (\(==\)), and not equal (\(!=\)) operate on all types. They result in a scalar Boolean. If the operand types do not match, then there must be a conversion from Section 4.1.10 “Implicit Conversions” applied to one operand that can make them match, in which case this conversion is done. For vectors, matrices, structures, and arrays, all components, fields, or elements of one operand must equal the corresponding components, fields, or elements in the other operand for the operands to be considered equal. To get a vector of component-wise equality results for vectors, use the built-in functions \texttt{equal} and \texttt{notEqual}.

- The logical binary operators and (\(\&\&\)), or (\(|\|\)), and exclusive or (\(^{\wedge}\)) operate only on two Boolean expressions and result in a Boolean expression. And (\(\&\&\)) will only evaluate the right hand operand if the left hand operand evaluated to \texttt{true}. Or (\(|\|\)) will only evaluate the right hand operand if the left hand operand evaluated to \texttt{false}. Exclusive or (\(^{\wedge}\)) will always evaluate both operands.

- The logical unary operator not (\(\!\)). It operates only on a Boolean expression and results in a Boolean expression. To operate on a vector, use the built-in function \texttt{not}.

- The sequence (, ) operator that operates on expressions by returning the type and value of the rightmost expression in a comma separated list of expressions. All expressions are evaluated, in order, from left to right.

- The ternary selection operator (?:). It operates on three expressions (\texttt{exp1 ? exp2 : exp3}). This operator evaluates the first expression, which must result in a scalar Boolean. If the result is true, it selects to evaluate the second expression, otherwise it selects to evaluate the third expression. Only one of the second and third expressions is evaluated. The second and third expressions can be any type, as long their types match, or there is a conversion in Section 4.1.10 “Implicit Conversions” that can be applied to one of the expressions to make their types match. This resulting matching type is the type of the entire expression.

- Operators and (\&), or (\(|\|\)), exclusive or (\(^{\wedge}\)), not (\(\!\)), right-shift (\(\gg\)), left-shift (\(\ll\)). These operators are reserved for future use.

- The one's complement operator (\(\sim\)). The operand must be of type signed or unsigned integer or integer vector, and the result is the one's complement of its operand; each bit of each component is complemented, including any sign bits.
• **The shift operators (<<) and (>>).** For both operators, the operands must be signed or unsigned integers or integer vectors. One operand can be signed while the other is unsigned. In all cases, the resulting type will be the same type as the left operand. If the first operand is a scalar, the second operand has to be a scalar as well. If the first operand is a vector, the second operand must be a scalar or a vector, and the result is computed component-wise. The result is undefined if the right operand is negative, or greater than or equal to the number of bits in the left expression's base type. The value of E1 << E2 is E1 (interpreted as a bit pattern) left-shifted by E2 bits. The value of E1 >> E2 is E1 right-shifted by E2 bit positions. If E1 is a signed integer, the right-shift will extend the sign bit. If E1 is an unsigned integer, the right-shift will zero-extend.

• **The bitwise operators and (&), exclusive-or (^), and inclusive-or (|).** The operands must be of type signed or unsigned integers or integer vectors. The operands cannot be vectors of differing size. If one operand is a scalar and the other a vector, the scalar is applied component-wise to the vector, resulting in the same type as the vector. The fundamental types of the operands (signed or unsigned) must match, and will be the resulting fundamental type. For and (&), the result is the bitwise-and function of the operands. For exclusive-or (^), the result is the bitwise exclusive-or function of the operands. For inclusive-or (|), the result is the bitwise inclusive-or function of the operands.

For a complete specification of the syntax of expressions, see Section 9 “Shading Language Grammar.”

### 5.10 Vector and Matrix Operations

With a few exceptions, operations are component-wise. Usually, when an operator operates on a vector or matrix, it is operating independently on each component of the vector or matrix, in a component-wise fashion. For example,

```c
vec3 v, u;
float f;

v = u + f;
```

will be equivalent to

```c
v.x = u.x + f;
v.y = u.y + f;
v.z = u.z + f;
```

And

```c
vec3 v, u, w;
w = v + u;
```

will be equivalent to

```c
w.x = v.x + u.x;
w.y = v.y + u.y;
w.z = v.z + u.z;
```

and likewise for most operators and all integer and floating point vector and matrix types. The exceptions are matrix multiplied by vector, vector multiplied by matrix, and matrix multiplied by matrix. These do not operate component-wise, but rather perform the correct linear algebraic multiply.
vec3 v, u;
mat3 m;

u = v * m;

is equivalent to

u.x = dot(v, m[0]); // m[0] is the left column of m
u.y = dot(v, m[1]); // dot(a, b) is the inner (dot) product of a and b
u.z = dot(v, m[2]);

And

u = m * v;

is equivalent to

u.x = m[0].x * v.x + m[1].x * v.y + m[2].x * v.z;
u.y = m[0].y * v.x + m[1].y * v.y + m[2].y * v.z;
u.z = m[0].z * v.x + m[1].z * v.y + m[2].z * v.z;

And

mat3 m, n, r;

r = m * n;

is equivalent to

r[0].x = m[0].x * n[0].x + m[1].x * n[0].y + m[2].x * n[0].z;
r[1].x = m[0].x * n[1].x + m[1].x * n[1].y + m[2].x * n[1].z;
r[2].x = m[0].x * n[2].x + m[1].x * n[2].y + m[2].x * n[2].z;

r[0].y = m[0].y * n[0].x + m[1].y * n[0].y + m[2].y * n[0].z;
r[1].y = m[0].y * n[1].x + m[1].y * n[1].y + m[2].y * n[1].z;
r[2].y = m[0].y * n[2].x + m[1].y * n[2].y + m[2].y * n[2].z;

r[0].z = m[0].z * n[0].x + m[1].z * n[0].y + m[2].z * n[0].z;
r[1].z = m[0].z * n[1].x + m[1].z * n[1].y + m[2].z * n[1].z;
r[2].z = m[0].z * n[2].x + m[1].z * n[2].y + m[2].z * n[2].z;

and similarly for other sizes of vectors and matrices.
The fundamental building blocks of the OpenGL Shading Language are:

- statements and declarations
- function definitions
- selection (if-else and switch-case-default)
- iteration (for, while, and do-while)
- jumps (discard, return, break, and continue)

The overall structure of a shader is as follows:

```
translation-unit:
global-declaration
translation-unit global-declaration
global-declaration:
function-definition
declaration
```

That is, a shader is a sequence of declarations and function bodies. Function bodies are defined as

```
function-definition:
  function-prototype { statement-list }
statement-list:
  statement
  statement-list statement
statement:
  compound-statement
  simple-statement
```

Curly braces are used to group sequences of statements into compound statements.

```
compound-statement:
  { statement-list }
```
6 Statements and Structure

\[
\text{simple-statement:}
\]
\[
\text{declaration-statement}
\]
\[
\text{expression-statement}
\]
\[
\text{selection-statement}
\]
\[
\text{iteration-statement}
\]
\[
\text{jump-statement}
\]

Simple declaration, expression, and jump statements end in a semi-colon.

This above is slightly simplified, and the complete grammar specified in Section 9 “Shading Language Grammar” should be used as the definitive specification.

Declarations and expressions have already been discussed.

6.1 Function Definitions

As indicated by the grammar above, a valid shader is a sequence of global declarations and function definitions. A function is declared as the following example shows:

\[
\text{// prototype}
\]
\[
\text{returnType functionName (type0 arg0, type1 arg1, ..., typen argn);}
\]

and a function is defined like

\[
\text{// definition}
\]
\[
\text{returnType functionName (type0 arg0, type1 arg1, ..., typen argn)}
\]
\[
\{
\text{// do some computation}
\text{return returnValuc;}
\}
\]

where \text{returnType} must be present and include a type. Each of the \text{typeN} must include a type and can optionally include a parameter qualifier and/or \text{const}.

A function is called by using its name followed by a list of arguments in parentheses.

Arrays are allowed as arguments and as the return type. In both cases, the array must be explicitly sized. An array is passed or returned by using just its name, without brackets, and the size of the array must match the size specified in the function's declaration.

Structures are also allowed as argument types. The return type can also be structure.

See Section 9 “Shading Language Grammar” for the definitive reference on the syntax to declare and define functions.

All functions must be either declared with a prototype or defined with a body before they are called. For example:

\[
\text{float myfunc (float f, \quad // f is an input parameter}
\text{out float g); \quad // g is an output parameter}
\]
Functions that return no value must be declared as `void`. Functions that accept no input arguments need not use `void` in the argument list because prototypes (or definitions) are required and therefore there is no ambiguity when an empty argument list "( )" is declared. The idiom "(void)" as a parameter list is provided for convenience.

Function names can be overloaded. The same function name can be used for multiple functions, as long as the parameter types differ. If a function name is declared twice with the same parameter types, then the return types and all qualifiers must also match, and it is the same function being declared. When function calls are resolved, an exact type match for all the arguments is sought. If an exact match is found, all other functions are ignored, and the exact match is used. If no exact match is found, then the implicit conversions in Section 4.1.10 “Implicit Conversions” will be applied to find a match. Mismatched types on input parameters (in ou in or default) must have a conversion from the calling argument type to the formal parameter type. Mismatched types on output parameters (out ou inout) must have a conversion from the formal parameter type to the calling argument type. When argument conversions are used to find a match, it is a semantic error if there are multiple ways to apply these conversions to make the call match more than one function.

For example,

```cpp
vec4 f(in vec4 x, out vec4 y);
vec4 f(in vec4 x, out ivec4 y); // okay, different argument type
int f(in vec4 x, out ivec4 y); // error, only return type differs
vec4 f(in vec4 x, in ivec4 y); // error, only qualifier differs
int f(const in vec4 x, out ivec4 y); // error, only qualifier differs
```

Calling the first two functions above with the following argument types yields

```cpp
f(vec4, vec4) // exact match of vec4 f(in vec4 x, out vec4 y)
f(vec4, ivec4) // exact match of vec4 f(in vec4 x, out ivec4 y)
f(ivec4, vec4) // error, convertible to both
f(ivec4, ivec4) // okay, convertible only to vec4 f(in vec4 x, out ivec4 y)
```

User-defined functions can have multiple declarations, but only one definition. A shader can redefine built-in functions. If a built-in function is redeclared in a shader (i.e. a prototype is visible) before a call to it, then the linker will only attempt to resolve that call within the set of shaders that are linked with it.

The function `main` is used as the entry point to a shader executable. A shader need not contain a function named `main`, but one shader in a set of shaders linked together to form a single shader executable must. This function takes no arguments, returns no value, and must be declared as type `void`:

```cpp
void main()
{
    ...
}
```

The function `main` can contain uses of `return`. See Section 6.4 “Jumps” for more details.

It is an error to declare or define a function `main` with any other parameters or return type.
6.1.1 Function Calling Conventions

Functions are called by value-return. This means input arguments are copied into the function at call time, and output arguments are copied back to the caller before function exit. Because the function works with local copies of parameters, there are no issues regarding aliasing of variables within a function. At call time, input arguments are evaluated in order, from left to right. However, the order in which output parameters are copied back to the caller is undefined. To control what parameters are copied in and/or out through a function definition or declaration:

- The keyword `in` is used as a qualifier to denote a parameter is to be copied in, but not copied out.
- The keyword `out` is used as a qualifier to denote a parameter is to be copied out, but not copied in. This should be used whenever possible to avoid unnecessarily copying parameters in.
- The keyword `inout` is used as a qualifier to denote the parameter is to be both copied in and copied out.
- A function parameter declared with no such qualifier means the same thing as specifying `in`.

All arguments are evaluated at call time, exactly once, in order, from left to right. Evaluation of an `in` parameter results in a value that is copied to the formal parameter. Evaluation of an `out` parameter results in an l-value that is used to copy out a value when the function returns. Evaluation of an `inout` parameter results in both a value and an l-value; the value is copied to the formal parameter at call time and the l-value is used to copy out a value when the function returns.

The order in which output parameters are copied back to the caller is undefined.

If the function matching described in the previous section required argument type conversions, these conversions are applied at copy-in and copy-out times.

In a function, writing to an input-only parameter is allowed. Only the function’s copy is modified. This can be prevented by declaring a parameter with the `const` qualifier.

When calling a function, expressions that do not evaluate to l-values cannot be passed to parameters declared as `out` or `inout`.

No qualifier is allowed on the return type of a function.

```
function-prototype :
    type function-name(const-qualifier parameter-qualifier type name array-specifier, ... )

type :
    any basic type, array type, structure name, or structure definition

const-qualifier :
    empty
    const

parameter-qualifier :
    empty
    in
    out
    inout
```
name :
  empty
  identifier

array-specifier :
  empty
  [ integral-constant-expression ]

However, the const qualifier cannot be used with out or inout. The above is used for function declarations (i.e. prototypes) and for function definitions. Hence, function definitions can have unnamed arguments.

Recursion is not allowed, not even statically. Static recursion is present if the static function call graph of the program contains cycles.

### 6.2 Selection

Conditional control flow in the shading language is done by either if, or if-else, or switch statements:

```
if (bool-expression)
  true-statement

or

if (bool-expression)
  true-statement
else
  false-statement
```

Where `switch-statement-list` is a list of zero or more `switch-statement` and other statements defined by the language, where `switch-statement` adds labels. That is

```
  switch-statement-list :
    switch-statement
    switch-statement-list switch-statement
```

If the an if-expression evaluates to true, then the first true-statement is executed. If it evaluates to false and there is an else part then false-the second statement is executed.
Any expression whose type evaluates to a Boolean can be used as the conditional expression bool-expression. Vector types are not accepted as the expression to if.

Conditionals can be nested.

The type of init-expression in a switch statement must be a scalar integer. If a case label has a constant-expression of equal value, then execution will continue after that label. Otherwise, if there is a default label, execution will continue after that label. Otherwise, execution skips the rest of the switch statement. It is an error to have more than one default or a replicated constant-expression. A break statement not nested in a loop or other switch statement (either not nested or nested only in if or if-else statements) will also skip the rest of the switch statement. Fall through labels are allowed, but it is an error to have no statement between a label and the end of the switch statement.

No case or default labels can be nested inside other flow control nested within their corresponding switch.

6.3 Iteration

For, while, and do loops are allowed as follows:

```markdown
for (init-expression; condition-expression; loop-expression)
  sub-statement

while (condition-expression)
  sub-statement

do
  statement
while (condition-expression)
```

See Section 9 “Shading Language Grammar” for the definitive specification of loops.

The for loop first evaluates the init-expression, then the condition-expression. If the condition-expression evaluates to true, then the body of the loop is executed. After the body is executed, a for loop will then evaluate the loop-expression, and then loop back to evaluate the condition-expression, repeating until the condition-expression evaluates to false. The loop is then exited, skipping its body and skipping its loop-expression. Variables modified by the loop-expression maintain their value after the loop is exited, provided they are still in scope. Variables declared in init-expression or condition-expression are only in scope until the end of the sub-statement of the for loop.

The while loop first evaluates the condition-expression. If true, then the body is executed. This is then repeated, until the condition-expression evaluates to false, exiting the loop and skipping its body. Variables declared in the condition-expression are only in scope until the end of the sub-statement of the while loop.

The do-while loop first executes the body, then executes the condition-expression. This is repeated until condition-expression evaluates to false, and then the loop is exited.

Expressions for condition-expression must evaluate to a Boolean.
6 Statements and Structure

Both the condition-expression and the init-expression can declare and initialize a variable, except in the do-while loop, which cannot declare a variable in its condition-expression. The variable’s scope lasts only until the end of the sub-statement that forms the body of the loop.

Loops can be nested.

Non-terminating loops are allowed. The consequences of very long or non-terminating loops are platform dependent.

6.4 Jumps

These are the jumps:

\[
\text{jump}_{-}\text{statement}: \\
\text{continue; } \\
\text{break; } \\
\text{return; } \\
\text{return expression; } \\
\text{discard; }  \quad \text{// in the fragment shader language only}
\]

There is no “goto” nor other non-structured flow of control.

The continue jump is used only in loops. It skips the remainder of the body of the inner most loop of which it is inside. For while and do-while loops, this jump is to the next evaluation of the loop condition-expression from which the loop continues as previously defined. For for loops, the jump is to the loop-expression, followed by the condition-expression.

The break jump can also be used only in loops and switch statements. It is simply an immediate exit of the inner-most loop or switch statements containing the break. No further execution of condition-expression, or loop-expression, or switch-statement is done.

The discard keyword is only allowed within fragment shaders. It can be used within a fragment shader to abandon the operation on the current fragment. This keyword causes the fragment to be discarded and no updates to any buffers will occur. It would typically be used within a conditional statement, for example:

\[
\text{if (intensity < 0.0)} \\
\text{discard;}
\]

A fragment shader may test a fragment’s alpha value and discard the fragment based on that test. However, it should be noted that coverage testing occurs after the fragment shader runs, and the coverage test can change the alpha value.

The return jump causes immediate exit of the current function. If it has expression then that is the return value for the function.

The function main can use return. This simply causes main to exit in the same way as when the end of the function had been reached. It does not imply a use of discard in a fragment shader. Using return in main before defining outputs will have the same behavior as reaching the end of main before defining outputs.
7 Built-in Variables

7.1 Vertex Shader Special Variables

Some OpenGL operations still continue to occur in fixed functionality between the vertex processor and the fragment processor. Other OpenGL operations continue to occur in fixed functionality after the fragment processor. Shaders communicate with the fixed functionality of OpenGL through the use of built-in variables.

These built-in vertex shader variables for communicating with fixed functionality are intrinsically declared as follows:

```glsl
out vec4 gl_Position;  // must be written to
out float gl_PointSize; // may be written to
in int gl_VertexID;
out float gl_ClipDistance[]; // may be written to
out vec4 gl_ClipVertex;  // may be written to, deprecated
```

The variable `gl_Position` is available only in the vertex language and is intended for writing the homogeneous vertex position. All executions of a well-formed vertex shader executable must write a value into this variable. It can be written at any time during shader execution. It may also be read back by a vertex shader after being written. This value will be used by primitive assembly, clipping, culling, and other fixed functionality operations that operate on primitives after vertex processing has occurred. Compilers may generate a diagnostic message if they detect `gl_Position` is not written, or read before being written, but not all such cases are detectable. Its value is undefined if the vertex shader executable and does not write `gl_Position`.

The variable `gl_PointSize` is available only in the vertex language and is intended for a vertex shader to write the size of the point to be rasterized. It is measured in pixels.

The variable `gl_VertexID` is a vertex shader an input variable that holds an integer index for the vertex, as defined by the OpenGL Graphics System Specification. While the variable `gl_VertexID` is always present, its value is not always defined. For details on when it is defined, see the "Shader Inputs" subsection of section 2.20.3 "Shader Execution" of the OpenGL Graphics System Specification, Version 3.0.

The variable `gl_ClipDistance` provides the forward compatible mechanism in the vertex shader for controlling user clipping. To use this, a vertex shader is responsible for maintaining a set of clip planes, computing the distance from the vertex to each clip plane, and storing distances to the plane in `gl_ClipDistance[i]` for each plane `i`. A distance of 0 means the vertex is on the plane, a positive distance means the vertex is inside the clip plane, and a negative distance means the point is outside the clip plane. The clip distances will be linearly interpolated across the primitive and the portion of the primitive with interpolated distances less than 0 will be clipped.
The `gl_ClipDistance` array is predeclared as unsized, and must be sized by the shader either redeclaring it with a size or indexing it only with integral constant expressions. This needs to size the array to include all the clip planes that are enabled via the OpenGL API; if the size does not include all enabled planes, results are undefined. The size can be at most `gl_MaxClipDistances`. The number of varying components (see `gl_MaxVaryingComponents`) consumed by `gl_ClipDistance` will match the size of the array, no matter how many planes are enabled. The shader must also set all values in `gl_ClipDistance` that have been enabled via the OpenGL API, or results are undefined. Values written into `gl_ClipDistance` for planes that are not enabled have no effect.

The variable `gl_ClipVertex` is deprecated. It is available only in the vertex language and provides a place for vertex shaders to write the coordinate to be used with the user clipping planes. The user must ensure the clip vertex and user clipping planes are defined in the same coordinate space. User clip planes work properly only under linear transform. It is undefined what happens under non-linear transform.

If a linked set of shaders forming the vertex stage contains no static write to `gl_ClipVertex` or `gl_ClipDistance`, but the application has requested clipping against user clip planes through the API, then the coordinate written to `gl_Position` is used for comparison against the user clip planes. This behavior is also deprecated. Writing to `gl_ClipDistance` is the preferred method for user clipping. It is an error for a shader to statically write both `gl_ClipVertex` and `gl_ClipDistance`.

If `gl_PointSize` or `gl_ClipVertex` are not written to, their values are undefined. If `gl_PointSize` is not written to, its value is undefined in subsequent pipe stages.

Any of these variables can be read back by the shader after writing to them, to retrieve what was written. Reading them before writing them results in undefined behavior. If they are written more than once, it is the last value written that is consumed by the subsequent operations.

These built-in variables have global scope.

### 7.2 Fragment Shader Special Variables

The built-in `special` variables that are accessible from a fragment shader are intrinsically declared as follows:

```glsl
in vec4  gl_FragCoord;
in bool  gl_FrontFacing;
in float gl_ClipDistance[];
out vec4  gl_FragColor;  // deprecated
out vec4  gl_FragData[gl_MaxDrawBuffers];  // deprecated
out float gl_FragDepth;
```

Except as noted below, they behave as other input and output variables.

The output of the fragment shader executable is processed by the fixed function operations at the back end of the OpenGL pipeline.

Fragment shaders output values to the OpenGL pipeline using the built-in variables `gl_FragColor`, `gl_FragData`, and `gl_FragDepth`, unless the `discard` keyword statement is executed. Both `gl_FragColor` and `gl_FragData` are deprecated; the preferred usage is to explicitly declare these outputs in the fragment shader using the `out` storage qualifier.
These variables may be written to more than once. If so, the last value assigned is the one used in the subsequent fixed function pipeline. The values written to these variables may be read back after writing them. Reading from these variables before writing to them results in an undefined value.

The fixed functionality computed depth for a fragment may be obtained by reading \texttt{gl\_FragCoord.z}, described below.

**Deprecated:** Writing to \texttt{gl\_FragColor} specifies the fragment color that will be used by the subsequent fixed functionality pipeline. If subsequent fixed functionality consumes fragment color and an execution of the fragment shader executable does not write a value to \texttt{gl\_FragColor} then the fragment color consumed is undefined.

If the frame buffer is configured as a color index buffer then behavior is undefined when using a fragment shader.

Writing to \texttt{gl\_FragDepth} will establish the depth value for the fragment being processed. If depth buffering is enabled, and no shader writes \texttt{gl\_FragDepth}, then the fixed function value for depth will be used as the fragment’s depth value. If a shader statically assigns a value to \texttt{gl\_FragDepth}, and there is an execution path through the shader that does not set \texttt{gl\_FragDepth}, then the value of the fragment’s depth may be undefined for executions of the shader that take that path. That is, if the set of linked fragment shaders statically contain a write to \texttt{gl\_FragDepth}, then it is responsible for always writing it.

(A shader contains a static assignment to a variable \texttt{x} if, after pre-processing, the shader contains a statement that would write to \texttt{x}, whether or not run-time flow of control will cause that statement to be executed.) [This moved to the previous section.]

**Deprecated:** The variable \texttt{gl\_FragData} is an array. Writing to \texttt{gl\_FragData[n]} specifies the fragment data that will be used by the subsequent fixed functionality pipeline for data \texttt{n}. If subsequent fixed functionality consumes fragment data and an execution of a fragment shader executable does not write a value to it, then the fragment data consumed is undefined.

If a shader statically assigns a value to \texttt{gl\_FragColor}, it may not assign a value to any element of \texttt{gl\_FragData}. If a shader statically writes a value to any element of \texttt{gl\_FragData}, it may not assign a value to \texttt{gl\_FragColor}. That is, a shader may assign values to either \texttt{gl\_FragColor} or \texttt{gl\_FragData}, but not both. Multiple shaders linked together must also consistently write just one of these variables. Similarly, if user declared output variables are in use (statically assigned to), then the built-in variables \texttt{gl\_FragColor} and \texttt{gl\_FragData} may not be assigned to. These incorrect usages all generate compile time errors.

If a shader executes the \texttt{discard} keyword, the fragment is discarded, and the values of any user-defined fragment outputs, \texttt{gl\_FragDepth}, \texttt{gl\_FragColor}, and \texttt{gl\_FragData} become irrelevant.

The variable \texttt{gl\_FragCoord} is available as a read-only input variable from within fragment shaders and it holds the window relative coordinates \texttt{x}, \texttt{y}, \texttt{z}, and \texttt{1/w} values for the fragment. If multi-sampling, this value can be for any location within the pixel, or one of the fragment samples. The use of \texttt{centroid\_in\_varyings} does not further restrict this value to be inside the current primitive. This value is the result of the fixed functionality that interpolates primitives after vertex processing to generate fragments. The \texttt{z} component is the depth value that would be used for the fragment’s depth if no shader contained \texttt{any} writes to \texttt{gl\_FragDepth}. This is useful for invariance if a shader conditionally computes \texttt{gl\_FragDepth} but otherwise wants the fixed functionality fragment depth.
Fragment shaders have access to the read-only built-in variable `gl_FrontFacing`, whose value is `true` if the fragment belongs to a front-facing primitive. One use of this is to emulate two-sided lighting by selecting one of two colors calculated by a vertex shader.

The built-in input variable `gl_ClipDistance` array contains linearly interpolated values for the vertex values written by the vertex shader to the `gl_ClipDistance` vertex output variable. This array must be sized in the fragment shader either implicitly or explicitly to be the same size as it was sized in the vertex shader. Only elements in this array that have clipping enabled will have defined values.

However, they do not behave like variables with no storage qualifier; their behavior is as described above. These built-in variables have global scope.

### 7.3 Vertex Shader Built-In Attributes Inputs

**Deprecated:** The following attribute predeclared input names built into the OpenGL are vertex language and can be used from within a vertex shader to access the current values of attributes declared by OpenGL state. All page numbers and notations are references to the OpenGL 1.4 specification.

```glsl
// Vertex Attributes, p. 19.
//
attribute vec4 gl_Color;       // deprecated
attribute vec4 gl_SecondaryColor; // deprecated
attribute vec3 gl_Normal;     // deprecated
attribute vec4 gl_Vertex;     // deprecated
attribute vec4 gl_MultiTexCoord0; // deprecated
attribute vec4 gl_MultiTexCoord1; // deprecated
attribute vec4 gl_MultiTexCoord2; // deprecated
attribute vec4 gl_MultiTexCoord3; // deprecated
attribute vec4 gl_MultiTexCoord4; // deprecated
attribute vec4 gl_MultiTexCoord5; // deprecated
attribute vec4 gl_MultiTexCoord6; // deprecated
attribute vec4 gl_MultiTexCoord7; // deprecated
attribute float gl_FogCoord;  // deprecated
```

### 7.4 Built-In Constants

The following built-in constants are provided to vertex and fragment shaders. The actual values used are implementation dependent, but must be at least the value shown. Some are deprecated, as indicated in comments.

```glsl
//
// Implementation dependent constants. The example values below
// are the minimum values allowed for these maximums.
//
const int gl_MaxLights = 8;                     // GL 1.0
const int gl_MaxTextureUnits = 16;              // GL 1.3
const int gl_MaxVertexAttribs = 16;             // ARB_vertex_shader
const int gl_MaxVertexUniformComponents = 512;  // ARB_vertex_shader
const int gl_MaxVaryingFloats = 64;             // ARB_vertex_shader
```
7 Built-in Variables

```c
const int gl_MaxVaryingComponents = 64; // ARB_vertex_shader
const int gl_MaxVertexTextureImageUnits = 16; // ARB_vertex_shader
const int gl_MaxCombinedTextureImageUnits = 16; // ARB_vertex_shader
const int gl_MaxTextureImageUnits = 16; // ARB_vertex_shader
const int gl_MaxFragmentUniformComponents = 64; // ARB_vertex_shader
const int gl_MaxDrawBuffers = 18; // proposed
const int gl_MaxClipDistances = 8; // deprecated

// The following are deprecated.
const int gl_MaxClipPlanes = 68; // deprecated
const int gl_MaxTextureCoords = 28; // deprecated
```

7.5 Built-In Uniform State

As an aid to accessing OpenGL processing state, the following uniform variables are built into the OpenGL Shading Language. All page section numbers and notations are references to the OpenGL Graphics System Specification, Version 3.0.

```
// Depth range in window coordinates, section 2.12.1 33 p.
struct gl_DepthRangeParameters {
    float near; // n
    float far;  // f
    float diff; // f - n
};
uniform gl_DepthRangeParameters gl_DepthRange;
```

The following state is deprecated:

```
// Deprecated Matrix state. p. 31, 32, 37, 39, 40.
uniform mat4 gl_ModelViewMatrix;
uniform mat4 gl_ProjectionMatrix;
uniform mat4 gl_ModelViewProjectionMatrix;
uniform mat4 gl_TextureMatrix[gl_MaxTextureCoords];
```

```
// Deprecated.
// Derived matrix state that provides inverse and transposed versions
// of the matrices above. Poorly conditioned matrices may result
// in unpredictable values in their inverse forms.
uniform mat3 gl_NormalMatrix; // transpose of the inverse of the
```
uniform mat4 gl_ModelViewMatrixInverse;
uniform mat4 gl_ProjectionMatrixInverse;
uniform mat4 gl_ModelViewProjectionMatrixInverse;
uniform mat4 gl_TextureMatrixInverse[gl_MaxTextureCoords];

uniform mat4 gl_ModelViewMatrixTranspose;
uniform mat4 gl_ProjectionMatrixTranspose;
uniform mat4 gl_ModelViewProjectionMatrixTranspose;
uniform mat4 gl_TextureMatrixTranspose[gl_MaxTextureCoords];

uniform mat4 gl_ModelViewMatrixInverseTranspose;
uniform mat4 gl_ProjectionMatrixInverseTranspose;
uniform mat4 gl_ModelViewProjectionMatrixInverseTranspose;
uniform mat4 gl_TextureMatrixInverseTranspose[gl_MaxTextureCoords];

//
//
uniform float gl_NormalScale;

//
//
uniform vec4 gl_ClipPlane[gl_MaxClipPlanes];

//
//
struct gl_PointParameters {
    float size;
    float sizeMin;
    float sizeMax;
    float fadeThresholdSize;
    float distanceConstantAttenuation;
    float distanceLinearAttenuation;
    float distanceQuadraticAttenuation;
};

uniform gl_PointParameters gl_Point;
```cpp
// Deprecated. Material State p. 50, 55.
struct gl_MaterialParameters {
    vec4 emission; // Ecm
    vec4 ambient;  // Acm
    vec4 diffuse;  // Dcm
    vec4 specular; // Scm
    float shininess; // Srm
};
uniform gl_MaterialParameters gl_FrontMaterial;
uniform gl_MaterialParameters gl_BackMaterial;

// Deprecated. Light State p. 50, 53, 55.
struct gl_LightSourceParameters {
    vec4 ambient;         // Acli
    vec4 diffuse;         // Dcli
    vec4 specular;        // Scli
    vec3 spotDirection;   // Sdl
    vec4 halfVector;      // Derived: Hi
    vec4 position;        // Ppl
    float spotExponent;   // Srl
    float spotCutoff;     // Cr
    float spotCosCutoff;  // Derived: cos(Cr)
        // (range: [0.0,90.0], 180.0)
    float constantAttenuation; // K0
    float linearAttenuation;  // K1
    float quadraticAttenuation; // K2
};
uniform gl_LightSourceParameters gl_LightSource[gl_MaxLights];

struct gl_LightModelParameters {
    vec4 ambient;  // Acs
};
uniform gl_LightModelParameters gl_LightModel;

// Deprecated.
// Derived state from products of light and material.
struct gl_LightModelProducts {
    vec4 sceneColor;    // Derived. Ecm + Acm * Acs
};
```
7 Built-in Variables

uniform gl_LightModelProducts gl_FrontLightModelProduct;
uniform gl_LightModelProducts gl_BackLightModelProduct;

struct gl_LightProducts {
  vec4  ambient;        // Acm * Acli
  vec4  diffuse;        // Dcm * Dcli
  vec4  specular;       // Scm * Scli
};

uniform gl_LightProducts gl_FrontLightProduct[gl_MaxLights];
uniform gl_LightProducts gl_BackLightProduct[gl_MaxLights];

//
uniform vec4  gl_TextureEnvColor[gl_MaxTextureUnits];
uniform vec4  gl_EyePlaneS[gl_MaxTextureCoords];
uniform vec4  gl_EyePlaneT[gl_MaxTextureCoords];
uniform vec4  gl_EyePlaneR[gl_MaxTextureCoords];
uniform vec4  gl_EyePlaneQ[gl_MaxTextureCoords];
uniform vec4  gl_ObjectPlaneS[gl_MaxTextureCoords];
uniform vec4  gl_ObjectPlaneT[gl_MaxTextureCoords];
uniform vec4  gl_ObjectPlaneR[gl_MaxTextureCoords];
uniform vec4  gl_ObjectPlaneQ[gl_MaxTextureCoords];

// Deprecated. Fog p. 161
//
struct gl_FogParameters {
  vec4  color;
  float density;
  float start;
  float end;
  float scale;   // Derived:  1.0 / (end - start)
};

uniform gl_FogParameters gl_Fog;

7.6 Built-In VaryingVertex Output and Fragment Input Variables

Unlike user-defined varying variables, the built-in varying variables don’t have a strict one-to-one correspondence between the vertex language and the fragment language.

Unlike user-defined interpolated variables, the mapping between the built-in vertex output variables to the built-in fragment input variables doesn't have a strict one-to-one correspondence. Two sets are provided, one for each language. Their relationship is described below.
It is deprecated to have the GL provide fixed functionality behavior for a programmable pipeline stage. For example, mixing a fixed functionality vertex stage with a programmable fragment stage is deprecated. Pipeline configurations where only a proper subset of stages are being used do not require the unused stages to have shaders.

The following built-in `varying` vertex output variables are available to write to in a vertex shader. A particular one should be written to if any functionality in a corresponding fragment shader or fixed pipeline uses it or state derived from it. Otherwise, behavior is undefined.

```glsl
varying out vec4 gl_FrontColor;
varying out vec4 gl_BackColor;
varying out vec4 gl_FrontSecondaryColor;
varying out vec4 gl_BackSecondaryColor;
```

The following are also present in a vertex shader, but are deprecated:

```glsl
varying out vec4 gl_TexCoord[];  // at most will be gl_MaxTextureCoords
varying out float gl_FogFragCoord;
```

For `gl_FogFragCoord` (deprecated), the value written will be used as the “c” value on page 160 in section 3.11 of the OpenGL 1.4 Specification: OpenGL Graphics System Specification, Version 3.0, by the fixed functionality pipeline. For example, if the z-coordinate of the fragment in eye space is desired as “c”, then that's what the vertex shader executable should write into `gl_FogFragCoord`.

As with all arrays, indices used to subscript `gl_TexCoord` (deprecated) must either be an integral constant expressions, or this array must be re-declared by the shader with a size. The size can be at most `gl_MaxTextureCoords`. Using indexes close to 0 may aid the implementation in preserving varying resources.

The following `varying` fragment input variables are available to read from in a fragment shader. The `gl_Color` and `gl_SecondaryColor` names are the same names as attributes passed to the vertex shader language. However, there is no name conflict, because attributes are visible only in vertex shaders and the following are only visible in a fragment shader.

```glsl
varying in vec4 gl_Color;
varying in vec4 gl_SecondaryColor;
varying in vec2 gl_PointCoord;
```

The following fragment inputs are also available in a fragment shader, but are deprecated:

```glsl
varying in float gl_FogFragCoord;
varying in vec4 gl_TexCoord[];
```

The values in `gl_Color` and `gl_SecondaryColor` will be derived automatically by the system from `gl_FrontColor`, `gl_BackColor`, `gl_FrontSecondaryColor`, and `gl_BackSecondaryColor` based on which face is visible. If fixed functionality is used for vertex processing, then `gl_FogFragCoord` will either be the z-coordinate of the fragment in eye space, or the interpolation of the fog coordinate, as described in section 3.11 3-10 of the OpenGL 1.4 Specification: OpenGL Graphics System Specification, Version 3.0. The `gl_TexCoord[]` values are the interpolated `gl_TexCoord[]` values from a vertex shader or the texture coordinates of any fixed pipeline based vertex functionality.
Indices to the fragment shader $gl\_TexCoord$ array are as described above in the vertex shader text.

The values in $gl\_PointCoord$ are two-dimensional coordinates indicating where within a point primitive the current fragment is located, when point sprites are enabled. They range from 0.0 to 1.0 across the point. If the current primitive is not a point, or if point sprites are not enabled, then the values read from $gl\_PointCoord$ are undefined.
8 Built-in Functions

The OpenGL Shading Language defines an assortment of built-in convenience functions for scalar and vector operations. Many of these built-in functions can be used in more than one type of shader, but some are intended to provide a direct mapping to hardware and so are available only for a specific type of shader.

The built-in functions basically fall into three categories:

- They expose some necessary hardware functionality in a convenient way such as accessing a texture map. There is no way in the language for these functions to be emulated by a shader.
- They represent a trivial operation (clamp, mix, etc.) that is very simple for the user to write, but they are very common and may have direct hardware support. It is a very hard problem for the compiler to map expressions to complex assembler instructions.
- They represent an operation graphics hardware is likely to accelerate at some point. The trigonometry functions fall into this category.

Many of the functions are similar to the same named ones in common C libraries, but they support vector input as well as the more traditional scalar input.

Applications should be encouraged to use the built-in functions rather than do the equivalent computations in their own shader code since the built-in functions are assumed to be optimal (e.g., perhaps supported directly in hardware).

User code can replace built-in functions with their own if they choose, by simply re-declaring and defining the same name and argument list. Because built-in functions are in a more outer scope than user built-in functions, doing this will hide all built-in functions with the same name as the re-declared function.

When the built-in functions are specified below, where the input arguments (and corresponding output) can be float, vec2, vec3, or vec4, genType is used as the argument. Where the input arguments (and corresponding output) can be int, ivec2, ivec3, or ivec4, genIType is used as the argument. Where the input arguments (and corresponding output) can be uint, uvec2, uvec3, or uvec4, genUType is used as the argument. For any specific use of a function, the actual type substituted for genType, genIType, or genUType has to be the same for all arguments and for the return type. Similarly for mat, which can be any matrix basic type.
8.1 Angle and Trigonometry Functions

Function parameters specified as *angle* are assumed to be in units of radians. In no case will any of these functions result in a divide by zero error. If the divisor of a ratio is 0, then results will be undefined.

These all operate component-wise. The description is per component.

<table>

<tr>
<td>genType <strong>atan</strong> (genType <em>y</em>, genType <em>x</em>)</td>
<td>Arc tangent. Returns an angle whose tangent is (y/x). The signs of <em>x</em> and <em>y</em> are used to determine what quadrant the angle is in. The range of values returned by this function is ( [-\pi, \pi] ). Results are undefined if <em>x</em> and <em>y</em> are both 0.</td>
</tr>
<tr>
<td>genType <strong>atan</strong> (genType <em>y_over_x</em>)</td>
<td>Arc tangent. Returns an angle whose tangent is (y_{\overline{x}}). The range of values returned by this function is ( \left[ -\frac{\pi}{2}, \frac{\pi}{2} \right] ).</td>
</tr>
</tbody>
</table>
### 8.1 Sine, Cosine, and Tangent Functions

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>genType sinh (genType x)</code></td>
<td>Returns the hyperbolic sine function ( \frac{e^x - e^{-x}}{2} )</td>
</tr>
<tr>
<td><code>genType cosh (genType x)</code></td>
<td>Returns the hyperbolic cosine function ( \frac{e^x + e^{-x}}{2} )</td>
</tr>
<tr>
<td><code>genType tanh (genType x)</code></td>
<td>Returns the hyperbolic tangent function ( \frac{\sinh(x)}{\cosh(x)} )</td>
</tr>
</tbody>
</table>

### 8.2 Exponential Functions

These all operate component-wise. The description is per component.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>genType pow (genType x, genType y)</code></td>
<td>Returns ( x ) raised to the ( y ) power, i.e., ( x^y )</td>
</tr>
<tr>
<td></td>
<td>Results are undefined if ( x &lt; 0 ).</td>
</tr>
<tr>
<td></td>
<td>Results are undefined if ( x = 0 ) and ( y &lt;= 0 ).</td>
</tr>
<tr>
<td><code>genType exp (genType x)</code></td>
<td>Returns the natural exponentiation of ( x ), i.e., ( e^x ).</td>
</tr>
<tr>
<td><code>genType log (genType x)</code></td>
<td>Returns the natural logarithm of ( x ), i.e., returns the value ( y )</td>
</tr>
<tr>
<td></td>
<td>which satisfies the equation ( x = e^y ).</td>
</tr>
<tr>
<td></td>
<td>Results are undefined if ( x &lt;= 0 ).</td>

<tr>
<td><code>genType exp2 (genType x)</code></td>
<td>Returns 2 raised to the ( x ) power, i.e., ( 2^x ).</td>
</tr>
<tr>
<td><code>genType log2 (genType x)</code></td>
<td>Returns the base 2 logarithm of ( x ), i.e., returns the value ( y )</td>
</tr>
<tr>
<td></td>
<td>which satisfies the equation ( x = 2^y ).</td>
</tr>
<tr>
<td></td>
<td>Results are undefined if ( x &lt;= 0 ).</td>
</tr>
</tbody>
</table>
8.3 Common Functions

These all operate component-wise. The description is per component.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>genType <strong>sqrt</strong> (genType x)</td>
<td>Returns $\sqrt{x}$. Results are undefined if $x &lt; 0$.</td>
</tr>
<tr>
<td>genType <strong>inversesqrt</strong> (genType x)</td>
<td>Returns $\frac{1}{\sqrt{x}}$. Results are undefined if $x \leq 0$.</td>
</tr>
<tr>
<td>genType <strong>abs</strong> (genType x)</td>
<td>Returns x if $x \geq 0$, otherwise it returns $-x$.</td>
</tr>
<tr>
<td>genIType <strong>abs</strong> (genIType x)</td>
<td>Returns 1.0 if $x &gt; 0$, 0.0 if $x = 0$, or $-1.0$ if $x &lt; 0$.</td>
</tr>
<tr>
<td>genType <strong>sign</strong> (genType x)</td>
<td>Returns 1.0 if $x &gt; 0$, 0.0 if $x = 0$, or $-1.0$ if $x &lt; 0$.</td>
</tr>
<tr>
<td>genIType <strong>sign</strong> (genIType x)</td>
<td>Returns a value equal to the nearest integer that is less than or equal to $x$.</td>
</tr>
<tr>
<td>genType <strong>floor</strong> (genType x)</td>
<td>Returns a value equal to the nearest integer to $x$ whose absolute value is not larger than the absolute value of $x$.</td>
</tr>
<tr>
<td>genType <strong>trunc</strong> (genType x)</td>
<td>Returns a value equal to the nearest integer to $x$. The fraction 0.5 will round in a direction chosen by the implementation, presumably the direction that is fastest. This includes the possibility that <strong>round</strong>($x$) returns the same value as <strong>roundEven</strong>($x$) for all values of $x$.</td>
</tr>
<tr>
<td>genType <strong>round</strong> (genType x)</td>
<td>Returns a value equal to the nearest integer to $x$. A fractional part of 0.5 will round toward the nearest even integer. (Both 3.5 and 4.5 for $x$ will return 4.0.)</td>
</tr>
<tr>
<td>genType <strong>roundEven</strong> (genType x)</td>
<td>Returns a value equal to the nearest integer that is greater than or equal to $x$.</td>
</tr>
<tr>
<td>genType <strong>ceil</strong> (genType x)</td>
<td>Returns $x - \text{floor} (x)$.</td>
</tr>
<tr>
<td>Syntax</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>genType mod (genType x, float y)</code></td>
<td>Modulus. Returns $x - y \times \text{floor}(x/y)$.</td>
</tr>
<tr>
<td><code>genType mod (genType x, genType y)</code></td>
<td>Returns the fractional part of $x$ and sets $i$ to the integer part (as a whole number floating point value). Both the return value and the output parameter will have the same sign as $x$.</td>
</tr>
<tr>
<td><code>genType modf (genType x, out genType i)</code></td>
<td>Returns $y$ if $y &lt; x$, otherwise it returns $x$.</td>
</tr>
<tr>
<td><code>genType min (genType x, genType y)</code></td>
<td>Returns $y$ if $y &lt; x$, otherwise it returns $x$.</td>
</tr>
<tr>
<td><code>genType max (genType x, genType y)</code></td>
<td>Returns $x$ if $x &lt; y$, otherwise it returns $x$.</td>
</tr>
<tr>
<td><code>genType clamp (genType x, genType minVal, genType maxVal)</code></td>
<td>Returns $\text{min}(\text{max}(x, \text{minVal}), \text{maxVal})$. Results are undefined if $\text{minVal} &gt; \text{maxVal}$.</td>
</tr>
<tr>
<td>Syntax</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>genType mix (genType x, genType y, genType a)</code></td>
<td>Returns the linear blend of ( x ) and ( y ), i.e. ( x (1-a) + y \cdot a )</td>
</tr>
<tr>
<td><code>genType mix (genType x, genType y, float a)</code></td>
<td>Selects which vector each returned component comes from. For a component of ( a ) that is <code>false</code>, the corresponding component of ( x ) is returned. For a component of ( a ) that is <code>true</code>, the corresponding component of ( y ) is returned. Components of ( x ) and ( y ) that are not selected are allowed to be invalid floating point values and will have no effect on the results. Thus, this provides different functionality than <code>genType mix(genType x, genType y, genType(a))</code> where ( a ) is a Boolean vector.</td>
</tr>
<tr>
<td><code>genType step (genType edge, genType x)</code></td>
<td>Returns 0.0 if ( x &lt; \text{edge} ), otherwise it returns 1.0.</td>
</tr>
</tbody>
</table>
| `genType step (float edge, genType x)` | Returns 0.0 if \( x \leq \text{edge0} \) and 1.0 if \( x \geq \text{edge1} \) and performs smooth Hermite interpolation between 0 and 1 when \( \text{edge0} < x < \text{edge1} \). This is useful in cases where you would want a threshold function with a smooth transition. This is equivalent to:  
   ```c
   genType t;
   t = clamp ((x – edge0) / (edge1 – edge0), 0, 1);
   return t * t * (3 – 2 * t);
   ```
   Results are undefined if \( \text{edge0} \geq \text{edge1} \). |
<p>| <code>bvec isnan (genType x)</code> | Returns <code>true</code> if ( x ) holds a NaN (not a number) representation in the underlying implementation's set of floating point representations. Returns <code>false</code> otherwise, including for implementations with no NaN representations. |</p>
<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bvec isinf (genType x)</code></td>
<td>Returns <code>true</code> if <code>x</code> holds a positive infinity or negative infinity representation in the underlying implementation's set of floating point representations. Returns <code>false</code> otherwise, including for implementations with no infinity representations.</td>
</tr>
</tbody>
</table>
8.4 Geometric Functions

These operate on vectors as vectors, not component-wise.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>float length (genType x)</td>
<td>Returns the length of vector x, i.e., $\sqrt{x[0]^2 + x[1]^2 + ...}$</td>
</tr>
<tr>
<td>float distance (genType p0, genType p1)</td>
<td>Returns the distance between p0 and p1, i.e. length (p0 – p1)</td>
</tr>
<tr>
<td>float dot (genType x, genType y)</td>
<td>Returns the dot product of x and y, i.e., $x[0] \cdot y[0] + x[1] \cdot y[1] + ...$</td>
</tr>
<tr>
<td>vec3 cross (vec3 x, vec3 y)</td>
<td>Returns the cross product of x and y, i.e. $\begin{bmatrix} x[1] \cdot y[2] - y[1] \cdot x[2] \ x[2] \cdot y[0] - y[2] \cdot x[0] \ x[0] \cdot y[1] - y[0] \cdot x[1] \end{bmatrix}$</td>
</tr>
<tr>
<td>genType normalize (genType x)</td>
<td>Returns a vector in the same direction as x but with a length of 1.</td>
</tr>
</tbody>
</table>
| vec4 ftransform() | Deprecated; use invariant. For vertex shaders only. This function will ensure that the incoming vertex value will be transformed in a way that produces exactly the same result as would be produced by OpenGL’s fixed functionality transform. It is intended to be used to compute gl_Position, e.g.,

$$\text{gl\_Position} = \text{ftransform}()$$

This function should be used, for example, when an application is rendering the same geometry in separate passes, and one pass uses the fixed functionality path to render and another pass uses programmable shaders. |
<p>| genType faceforward (genType N, genType I, genType Nref) | If dot(Nref, I) &lt; 0 return N, otherwise return –N. |</p>
<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
</table>
| genType `reflect` (genType `I`, genType `N`) | For the incident vector `I` and surface orientation `N`, returns the reflection direction:  
  \[ I \rightarrow 2 \cdot \text{dot}(N, I) \cdot N \]  
  `N` must already be normalized in order to achieve the desired result. |
| genType `refract` (genType `I`, genType `N`, float `eta`) | For the incident vector `I` and surface normal `N`, and the ratio of indices of refraction `eta`, return the refraction vector. The result is computed by  
  \[ k = 1.0 - \eta \cdot \eta \cdot (1.0 - \text{dot}(N, I) \cdot \text{dot}(N, I)) \]  
  if \( k < 0.0 \)  
    return genType(0.0)  
  else  
    return \( \eta \cdot I - (\eta \cdot \text{dot}(N, I) + \text{sqrt}(k)) \cdot N \)  
  The input parameters for the incident vector `I` and the surface normal `N` must already be normalized to get the desired results. |
### 8.5 Matrix Functions

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mat <code>matrixCompMult (mat x, mat y)</code></td>
<td>Multiply matrix <code>x</code> by matrix <code>y</code> component-wise, i.e., <code>result[i][j]</code> is the scalar product of <code>x[i][j]</code> and <code>y[i][j]</code>. Note: to get linear algebraic matrix multiplication, use the multiply operator (*)</td>
</tr>
<tr>
<td><code>mat2 outerProduct(vec2 c, vec2 r)</code></td>
<td>Treats the first parameter <code>c</code> as a column vector (matrix with one column) and the second parameter <code>r</code> as a row vector (matrix with one row) and does a linear algebraic matrix multiply <code>c * r</code>, yielding a matrix whose number of rows is the number of components in <code>c</code> and whose number of columns is the number of components in <code>r</code>.</td>
</tr>
<tr>
<td><code>mat2x3 outerProduct(vec3 c, vec2 r)</code></td>
<td></td>
</tr>
<tr>
<td><code>mat3x2 outerProduct(vec2 c, vec3 r)</code></td>
<td></td>
</tr>
<tr>
<td><code>mat2x4 outerProduct(vec4 c, vec2 r)</code></td>

<tr>
<td>mat4x3 <code>transpose(mat3x4 m)</code></td>
<td></td>
</tr>
</tbody>
</table>
## 8.6 Vector Relational Functions

Relational and equality operators (<, <=, >, >=, ==, !=) are defined to produce scalar Boolean results. For vector results, use the following built-in functions. Below, “bvec” is a placeholder for one of `bvec2`, `bvec3`, or `bvec4`, “ivec” is a placeholder for one of `ivec2`, `ivec3`, or `ivec4`, “uvec” is a placeholder for `uvec2`, `uvec3`, or `uvec4`, and “vec” is a placeholder for `vec2`, `vec3`, or `vec4`. In all cases, the sizes of the input and return vectors for any particular call must match.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bvec lessThan(vec x, vec y)</code></td>
<td>Returns the component-wise compare of $x &lt; y$.</td>
</tr>
<tr>
<td><code>bvec lessThan(ivec x, ivec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec lessThan(uvec x, uvec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec lessThanEqual(vec x, vec y)</code></td>
<td>Returns the component-wise compare of $x \leq y$.</td>
</tr>
<tr>
<td><code>bvec lessThanEqual(ivec x, ivec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec lessThanEqual(uvec x, uvec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec greaterThan(vec x, vec y)</code></td>
<td>Returns the component-wise compare of $x &gt; y$.</td>
</tr>
<tr>
<td><code>bvec greaterThan(ivec x, ivec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec greaterThan(uvec x, uvec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec greaterThanEqual(vec x, vec y)</code></td>
<td>Returns the component-wise compare of $x \geq y$.</td>
</tr>
<tr>
<td><code>bvec greaterThanEqual(ivec x, ivec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec greaterThanEqual(uvec x, uvec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec equal(vec x, vec y)</code></td>
<td>Returns the component-wise compare of $x == y$.</td>
</tr>
<tr>
<td><code>bvec equal(ivec x, ivec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec equal(uvec x, uvec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec equal(bvec x, bvec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec notEqual(vec x, vec y)</code></td>
<td>Returns the component-wise compare of $x \neq y$.</td>
</tr>
<tr>
<td><code>bvec notEqual(ivec x, ivec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec notEqual(uvec x, uvec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bvec notEqual(bvec x, bvec y)</code></td>
<td></td>
</tr>
<tr>
<td><code>bool any(bvec x)</code></td>
<td>Returns true if any component of $x$ is <code>true</code>.</td>
</tr>
<tr>
<td><code>bool all(bvec x)</code></td>
<td>Returns true only if all components of $x$ are <code>true</code>.</td>
</tr>
<tr>
<td><code>bvec not(bvec x)</code></td>
<td>Returns the component-wise logical complement of $x$.</td>
</tr>
</tbody>
</table>
8.7 Texture Lookup Functions

Texture lookup functions are available to both vertex and fragment shaders. However, level of detail is not implicitly computed by fixed functionality for vertex shaders, so there are some differences in operation between vertex and fragment texture lookups. The functions in the table below provide access to textures through samplers, as set up through the OpenGL API. Texture properties such as size, pixel format, number of dimensions, filtering method, number of mipmap levels, depth comparison, and so on are also defined by OpenGL API calls. Such properties are taken into account as the texture is accessed.

Texture data can be stored by the GL as floating point, unsigned normalized integer, unsigned integer or signed integer data. This is determined by the type of the internal format of the texture. Texture lookups on unsigned normalized integer and floating point data return floating point values in the range [0, 1].

Texture lookup functions are provided that can return their result as floating point, unsigned integer or signed integer, depending on the sampler type passed to the lookup function. Care must be taken to use the right sampler type for texture access. The following table lists the supported combinations of sampler types and texture internal formats. Blank entries are unsupported. Doing a texture lookup will return undefined values for unsupported combinations.

<table>
<thead>
<tr>
<th>Internal Texture Format</th>
<th>Floating Point Sampler Types</th>
<th>Signed Integer Sampler Types</th>
<th>Unsigned Integer Sampler Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating point</td>
<td>Supported</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Normalized Integer</td>
<td></td>
<td>Supported</td>
<td></td>
</tr>
<tr>
<td>Signed Integer</td>
<td></td>
<td></td>
<td>Supported</td>
</tr>
<tr>
<td>Unsigned Integer</td>
<td></td>
<td></td>
<td>Supported</td>
</tr>
</tbody>
</table>

If an integer sampler type is used, the result of a texture lookup is an ivec4. If an unsigned integer sampler type is used, the result of a texture lookup is a uvec4. If a floating point sampler type is used, the result of a texture lookup is a vec4, where each component is in the range [0, 1].

In the prototypes below, the “g” in the return type “gvec4” is used as a placeholder for nothing. “i”, or “u”, making a return type of vec4, ivec4, or uvec4. In these cases, the sampler argument type also starts with “g”, indicating the same substitution done on the return type; it is either a floating point, signed integer, or unsigned integer sampler, matching the basic type of the return type, as described above.

For shadow forms (the sampler parameter is a shadow-type), a depth comparison lookup on the depth texture bound to sampler is done as described in section 3.9.14 of the OpenGL Graphics System Specification, Version 3.0. See the table below for which component specifies Dref. The texture bound to sampler must be a depth texture, or results are undefined. If a non-shadow texture call is made to a sampler that represents a depth texture with depth comparisons turned on, then results are undefined. If a shadow texture call is made to a sampler that represents a depth texture with depth comparisons turned off, then results are undefined. If a shadow texture call is made to a sampler that does not represent a depth texture, then results are undefined.
In all functions below, the *bias* parameter is optional for fragment shaders. The *bias* parameter is not accepted in a vertex shader. For a fragment shader, if *bias* is present, it is added to the **implicit** calculated level of detail prior to performing the texture access operation. If the *bias* parameter is not provided, then the implementation automatically selects level of detail.

The implicit level of detail is selected as follows: For a texture that is not mip-mapped, the texture is used directly. If it is mip-mapped and running in a fragment shader, the LOD computed by the implementation is used to do the texture lookup. If it is mip-mapped and running on the vertex shader, then the base texture is used.

For the “Lod” functions, *lod* is directly used as the level of detail. The built-ins suffixed with “Lod” are allowed only in a vertex shader.

Some texture functions (non-“Lod” and non-“Grad” versions) may require implicit derivatives. Implicit derivatives are undefined within non-uniform control flow and for vertex shader texture fetches.

For **Cube** forms, the direction of *P* is used to select which face to do a 2-dimensional texture lookup in, as described in section 3.9.6 in the OpenGL Graphics System Specification, Version 3.0.

For **Array** forms, the array layer used will be

\[
\text{max}(0, \min(d - 1, \text{floor}(\text{layer} + 0.5)))
\]

where *d* is the depth of the texture array and *layer* comes from the component indicated in the tables below.
<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int <code>textureSize</code> (gsampler1D sampler, int lod)</td>
<td>Returns the dimensions of level <code>lod</code> for the texture bound to <code>sampler</code>, as described in section 2.20.4 of the OpenGL Graphics System Specification, Version 3.0, under &quot;Texture Size Query&quot;. The components in the return value are filled in, in order, with the width, height, depth of the texture. For the array forms, the last component of the return value is the number of layers in the texture array.</td>
</tr>
<tr>
<td>ivec2 <code>textureSize</code> (gsampler2D sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec3 <code>textureSize</code> (gsampler3D sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec2 <code>textureSize</code> (gsamplerCube sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec2 <code>textureSize</code> (gsamplerCubeShadow sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec2 <code>textureSize</code> (gsampler1DArray sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec3 <code>textureSize</code> (gsampler2DArray sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec2 <code>textureSize</code> (sampler1DShadow sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec2 <code>textureSize</code> (sampler2DShadow sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec2 <code>textureSize</code> (samplerCubeShadow sampler, int lod)</td>
<td></td>

<tr>
<td>ivec2 <code>textureSize</code> (samplerCubeArrayShadow sampler, int lod)</td>
<td></td>
</tr>
<tr>
<td>ivec3 <code>textureSize</code> (sampler2DArrayShadow sampler, int lod)</td>
<td></td>
</tr>
</tbody>
</table>

| gvec4 `texture` (gsampler1D sampler, float P [, float bias]) | Use the texture coordinate `P` to do a texture lookup in the texture currently bound to `sampler`. The last component of `P` is used as `D_{ref}` for the shadow forms. For array forms, the array layer comes from the last component of `P` in the non-shadow forms, and the second to last component of `P` in the shadow forms. |
| gvec4 `texture` (gsampler2D sampler, vec2 P [, float bias]) |
| gvec4 `texture` (gsampler3D sampler, vec3 P [, float bias]) |
| gvec4 `texture` (gsamplerCube sampler, vec3 P [, float bias]) |
| gvec4 `texture` (gsamplerCubeShadow sampler, vec4 P [, float bias]) |
| gvec4 `texture` (gsampler1DArray sampler, vec2 P [, float bias]) |
| gvec4 `texture` (gsampler2DArray sampler, vec3 P [, float bias]) |
| gvec4 `texture` (gsampler1DArrayShadow sampler, vec3 P [, float bias]) |
| gvec4 `texture` (gsampler2DArrayShadow sampler, vec4 P) |

<p>| gvec4 <code>textureProj</code> (gsampler1D sampler, vec2 P [, float bias]) | Do a texture lookup with projection. The texture coordinates consumed from <code>P</code>, not including the last component of <code>P</code>, are divided by the last component of <code>P</code>. The resulting 3rd component of <code>P</code> in the shadow forms is used as <code>D_{ref}</code>. After these values are computed, texture lookup proceeds as in <code>texture</code>. |
| gvec4 <code>textureProj</code> (gsampler2D sampler, vec3 P [, float bias]) |
| gvec4 <code>textureProj</code> (gsampler3D sampler, vec4 P [, float bias]) |
| gvec4 <code>textureProj</code> (gsamplerCube sampler, vec4 P [, float bias]) |
| gvec4 <code>textureProj</code> (gsamplerCubeShadow sampler, vec4 P [, float bias]) |
| float <code>textureProj</code> (sampler1DShadow sampler, vec4 P [, float bias]) |
| float <code>textureProj</code> (sampler2DShadow sampler, vec4 P [, float bias]) |</p>
<table>

<td>gvec4 textureOffset (gsampler1D sampler, float P, int offset, float bias)</td>
<td>Do a texture lookup as in texture but with offset added to the ((u, v, w)) texel coordinates before looking up each texel. The offset value must be a constant expression. A limited range of offset values are supported; the minimum and maximum offset values are implementation-dependent and given by MIN_PROGRAM_TEXEL_OFFSET and MAX_PROGRAM_TEXEL_OFFSET, respectively. Note that offset does not apply to the layer coordinate for texture arrays. This is explained in detail in section 3.9.7 of the OpenGL Graphics System Specification, Version 3.0, where offset is ((\delta_u, \delta_v, \delta_w)). Note that texel offsets are also not supported for cube maps.</td>

## 8.8 Fragment Processing Functions

Fragment processing functions are only available in fragment shaders. Derivatives may be computationally expensive and/or numerically unstable. Therefore, an OpenGL implementation may approximate the true derivatives by using a fast but not entirely accurate derivative computation. Derivatives are undefined within non-uniform control flow.

The expected behavior of a derivative is specified using forward/backward differencing.

**Forward differencing:**

\[
F(x+dx) - F(x) \sim dFdx(x) \cdot dx \quad 1a
\]

\[
dFdx(x) \sim \frac{F(x+dx) - F(x)}{dx} \quad 1b
\]
8 Built-in Functions

Backward differencing:

\[
F(x - dx) - F(x) \sim -dFdx(x) \cdot dx
\]  

\[
dFdx(x) \sim \frac{F(x) - F(x - dx)}{dx}
\]

With single-sample rasterization, \(dx \leq 1.0\) in equations 1b and 2b. For multi-sample rasterization, \(dx < 2.0\) in equations 1b and 2b.

\(dFdy\) is approximated similarly, with \(y\) replacing \(x\).

A GL implementation may use the above or other methods to perform the calculation, subject to the following conditions:

1. The method may use piecewise linear approximations. Such linear approximations imply that higher order derivatives, \(dFdx(dFdx(x))\) and above, are undefined.

2. The method may assume that the function evaluated is continuous. Therefore derivatives within the body of a non-uniform conditional are undefined.

3. The method may differ per fragment, subject to the constraint that the method may vary by window coordinates, not screen coordinates. The invariance requirement described in section 3.24 of the OpenGL 1.4 specification, OpenGL Graphics System Specification, Version 3.0, is relaxed for derivative calculations, because the method may be a function of fragment location.

Other properties that are desirable, but not required, are:

4. Functions should be evaluated within the interior of a primitive (interpolated, not extrapolated).

5. Functions for \(dFdx\) should be evaluated while holding \(y\) constant. Functions for \(dFdy\) should be evaluated while holding \(x\) constant. However, mixed higher order derivatives, like \(dFdx(dFdy(y))\) and \(dFdy(dFdx(x))\) are undefined.

6. Derivatives of constant arguments should be 0.

In some implementations, varying degrees of derivative accuracy may be obtained by providing GL hints (section 5.6 of the OpenGL 1.4 specification, OpenGL Graphics System Specification, Version 3.0), allowing a user to make an image quality versus speed trade off.
8 Built-in Functions

<table>

</tr>
</tbody>
</table>

### 8.9 Noise Functions

Noise functions are available to both fragment and vertex shaders. They are stochastic functions that can be used to increase visual complexity. Values returned by the following noise functions give the appearance of randomness, but are not truly random. The noise functions below are defined to have the following characteristics:

- The return value(s) are always in the range \([-1.0,1.0]\), and cover at least the range \([-0.6, 0.6]\), with a Gaussian-like distribution.
- The return value(s) have an overall average of 0.0
- They are repeatable, in that a particular input value will always produce the same return value
- They are statistically invariant under rotation (i.e., no matter how the domain is rotated, it has the same statistical character)
- They have a statistical invariance under translation (i.e., no matter how the domain is translated, it has the same statistical character)
- They typically give different results under translation.
- The spatial frequency is narrowly concentrated, centered somewhere between 0.5 to 1.0.
- They are \(C^1\) continuous everywhere (i.e., the first derivative is continuous)

10 Issues

2. How do we do flat shading?
   
   Alternate Resolution: Add `flat` qualifier for varyings.
   
   Alternate Resolution: Add `flat` qualifier for varyings that obeys shade mode.
   
   Resolution: Add `flat`, but restrict it to `gl_*color varyings` with the same semantics as flat in 2.x. In the API, there is immutable state in the program object that sets the default. Also add `smooth` to the language for overriding when the default is `flat`.

3. What is the complete list of fundamental data types transparently exchangeable?
   
   Alternate Resolution: Just floating point types.
   
   Resolution: `float`, `int`, and `bool`.

4. Are there any cache flushing issues around writing to bound partitions? \(\rightarrow\) See issue 9.

5. Complex matrix \(\rightarrow\) matrix constructors.
   
   Resolution: Defer.

6. How do we do two-sided coloring? This interacts with clamping, because fixed hardware dealing with this would also clamp.
   
   No language impact.
   
   Resolution: A two-sided enable goes into program object as immutable state. It is not a link error if one-sided is enabled and back-color is written. All other mis-matches are just undefined.

7. Do we do clamping? How is this determined?
   
   No language impact.
   
   Resolution: Have immutable state in the program object that says whether color input to the rasterizer is clamped. Add another for fragment output.

9. What about cache flushing common blocks? Is it bound during writes? Do we expect all shader hardware to have to write to the same resource shaders read common blocks from?
   
   We might expect separate resources. But, this is part of a much bigger problem that needs to be resolved in the API.
   
   Alternative 1: Implementations use API calls like `draw` to be responsible for implicitly refreshing the resource.
   
   Alternative 2: Add an explicit call to say you are done changing it.
   
   Resolution: See API spec. resolution.

10. Problem with built-in texture function names, how do we reduce?
    
    - we will at least drop the texture type from the function name
10 Issues

- consider using named parameters
- consider using programs to specify the lookup

11. Do we want application named fragment-shader outputs.
   Resolution: Yes.

12. Should we switch to application-assigned slots for the varying linkage between vertex and fragment shaders?
   Alternate Resolution: No. Keep doing it the way 2.x does it.
   Resolution: This is an API issue. See API spec.

13. Can we query declared varyings?
   Resolution: Yes. This is an API issue. See API spec.

14. Are there any sRGB impacts to the language?
   Resolution: No. The shader pipe assumes linear space. sRGB is in filtering state going into the shader and in output space after leaving the shader.

15. How do you declare a flat varying? We said the only variables that can be flat are "gl_*color", but those are already declared.
   Resolution: Just like invariant, allow a built-in variable to be redeclared as long as the redeclaration just adds/changes the qualifiers. Note we also allow redeclarations to give an array explicit size.
   -> don't allow bad redeclarations of built-ins

16. Should allow variations in the value of a flat varying across a triangle? (For the case where real interpolators are still used and might not get exactly the same result for each pixel.)
   Resolution: No. The value is invariant across the triangle.

17. Do precision qualifiers have to match? If the intention is to aid porting, not really save space/power, it is actually more helpful if they don't have to match like they do in the ES spec.
   Alternate Resolution: No. Allow precision mismatches. This would imply all precisions are interchangeable, hence we could formalize that and just say the language recognizes the keywords, but they don't have any meaning. This means the specification is very simple and easy to understand.
   -> get the most recent ES spec to see what it does.
   Resolution: precision qualifiers have no semantics.

18. Does an application running on mixed hardware have the same layout for a common block for all shaders the common block is in? Different contexts can be for different adapters.
   Resolution: Offsets could be different on different hardware. But, if they are successfully created, then the offsets will match, and common blocks can be shared. Future could consider things like “packed common” or “vec4 common” ...

19. Do we support initializers inside of common blocks? How does the API handle them? We already chose the language syntax that makes it easy to provide.
   Resolution: Yes. Face-to-face strawpoll: for 9, against 3, abstain 5.
21. Does flat/smooth/default have to match across stages?

Alternate Resolution A. No. Exclude flat/smooth from other stage's languages, and say it's really a fragment shader control. Problem is that depends on implementation and where the interpolation happens.

Alternate Resolution B. It is interfaces whose sides have to match, not shaders. The output of one stage has to match the input of the next stage. The input to a stage does not have to match the output of that stage. Semantics have been, but can be more clearly stated as: the variable the shader is manipulating was copied in from the input interface at the beginning and copied out to the output interface at the end.

Alternate Resolution C. Build on B, take inout and in and out into account, with it's benefit of allowing reuse of names. That means allowing both “in color” and “out color” in the same shader to mean the same thing as “inout color”. Then, they can be decorated differently “in color” and “out flat color” without contradiction because the decorations are modifying the interface, not the variable the shader is manipulating. Note that even without this issue we need to say what happens with either “inout color” or “in color; out color”. See issue 24.

Resolution: Interfaces match. Inputs and outputs within a shader do not have to match.

22. Does invariant still have to match across stages?

Resolution: Yes.

23. Do we want to get rid of gl_DepthRange? Getting rid of it only really makes sense if it's the only remaining state that has to be tracked.

Resolution: No, keep it.

24. If a shader declares “inout color” and then does not use the variable color (but the previous and/or following stage did use color), what happens?

Alternate Resolution. There is an implicit copy from the input color to the output color. Note this is a corollary anyway of the idea that input variables are copied in at start of shader and copied out to the output at the end of the shader. Note the interaction with this and basing set of varyings off of declarations vs. static or active use.

Resolution: Remove inout. This also fixes interpolation qualifier ambiguities.

25. What API mechanism do we use to do #include.

Alternate Resolution A: Simple database of names mapped to include strings on the server in the context. Shader has includes that use those names, and compile time does string substitutions from the simple database.

Alternate Resolution B: Rob's proposal. Similar to A, but strings are stored as “text objects”. More differences... see Rob's email.

Alternative Resolution C: Pass in each time a mapping of names to strings that's used by that compile.

Alternative Resolution D:

Alternative Resolution E: No #include.

Alternative Resolution F: Re-use shader objects: give them names, include by name. Requires changing the semantics of shader object to not parse shaders that have a name. Shaders that are the roots of compile cannot have names.

Resolution: This is handled by the API spec., through new objects for storing text strings.

26. Do we want to restrict switch to something simpler than C?
Resolution: Yes. No case inside flow control.

27. Can precision qualifiers be specified to do nothing instead of ES functionality?
   Resolution: leave ES-like functionality to extensions.

30. Are diagnostics for included files identifying locations as a triple (name string, string number, line number) or a pair (name string, line number). The implication being that the API sets the included text either as an array of strings or a single string. What does __FILE__ return?
   Resolution: As a pair. __FILE__ can return a string or a number, depending on the context.

32. Are we allowing bool/int in common blocks now, just like we do for the default partition?
   Resolution: Yes, put bool/int back into common blocks.

35. Do we want to say “centroid in” or “in centroid”, and similarly for smooth and flat? May have implications to expressing aliasing of varying with longer chains of qualifiers.
   Resolution: “centroid in”

36. What packing rules go in the language spec.?
   Resolution: It depends on whether future mechanisms for influencing packing are in the API or in the language. For now, the language spec. will specify the packing rules if a common block contains nothing but vec4s.

37. Are we removing user clip planes? Need to remove gl_ClipVertex.
   Resolution: No. For 1.30, keep gl_ClipVertex with its previous semantics. If gl_ClipVertex is not statically written, then gl_Position is used instead for clipping against user planes if they've been enabled. Also, add gl_ClipDistance.

38. Do we need to add any guarantees of precision of pass through data? Like 16 bits of color?
   Resolution: Deferred.

39. int(uint) and uint(int) are not conversions, they are reinterprets. This is a poor consistency in the language.
   Resolution: These are constructors, not type casts, which can do what they want. In this case they reinterpret, even though in other cases they convert.

40. How should the number of clip distances be set? How does this relate to API side enables? How does it relate to sizing the gl_ClipDistance array in the language?
   Resolution: Use enables.

41. Do we need to specify the precision of integer division?

42. Is the API adding support for #include? If not, remove from language.
   Resolution: Remove.

43. Some gl_VertexID description seems like it does not belong in the language spec.
   Done.

44. What needs to be said about transform feedback of built-in vertex outputs?
   Resolution: Nothing.
45. Still need to finish some ES synchronization (a set of pretty small details).

46. Lacking a partition scheme that's memory efficient for the case of lots of inactive uniforms declared in a common block (partition).

   Resolution: This is unnecessary. Having just the default partition (non-common globals) support this space optimization is sufficient, as it is not for sharing between programs and offsets always have to be queried.

47. Need more clarity on the effects of \texttt{uint vs int}. It appears to allow binary operations between an int and a uint, but doesn't really say what happens.

   Resolution: No implicit conversions; some operators are defined to take mixed operands, most are not.

48. List deprecated features in one place.

   Resolution. Yes.

49. Should the token-pasting language say that that results of the token pasting are then further processed by the preprocessor?

   Resolution: Yes.

50. \texttt{flat, noperspective, centroid, smooth axes, combinations, etc.} Is there an issue here?

51. broader support for mixing signed and unsigned in an expression

   dup. of 47

52. deprecating \texttt{gl\_FragColor} deprecates broadcast. Is that okay?

   Resolution: Yes.

53. What does "Not having shaders for programming all programmable stages..." mean to commands like \texttt{DrawPixels} that today run a fragment shader without a vertex shader. Do you have to make up a dummy vertex shader? Of course, with fixed-function vertex attributes (and thus RasterPos attributes) gone, it seems like \texttt{DrawPixels} (and Bitmap) as we know and love (?) it today would have to go. Not having seen a list of deprecated features for OpenGL 3.0, I have no idea if it's already on the list.

   Resolution: All programmable stages that are being used must have shaders provided for those stages. (Don't mention programs.)

54. Should we remove \texttt{row\_major} from the language.

   Resolution: Yes.

55. Should we add \texttt{gl\_ClipDistance} as input to the fragment shader.

   Resolution: Yes.

56. Don't say 1.2 and 1.1 are not accepted.

   Resolution: Yes, accept 1.1 and 1.2.

57. Do we have user-defined flat variables?

   Resolution: Yes. Fix spec. inconsistency. Only way to have integer varyings.

58. Should we really remove functionality instead of deprecate it?
Resolution: Deprecate before remove. Read API spec. appendix.

59. Can a global out redeclare the same name as a global in?
   -Resolution: No.
