NVIDIA OpenGL Extension Specifications

February 22, 2008

This document is an abridged collection of OpenGL extension specifications limited to those extensions for *new* OpenGL functionality introduced by the GeForce 8 Series (G8*x*) architecture. See the unabridged document "NVIDIA OpenGL Extension Specifications" for a complete collection.

NVIDIA-specific OpenGL extension specifications, possibly more up-to-date, can be found at:

http://developer.nvidia.com/view.asp?IO=nvidia_opengl_specs

Other OpenGL extension specifications can be found at:

http://oss.sgi.com/projects/ogl-sample/registry/

Corrections? Email opengl-specs@nvidia.com

Table of Contents

Table of NVIDIA OpenGL Extension Support

Extension	NV1*x*	NV2*x*	*NV3x*	*NV4x*	*G8x*	Notes
ARB_color_buffer_float				R75	X	
ARB_depth_texture		R25+	X	X	X	1.4 functionality
ARB_draw_buffers				R75	X	2.0 functionality
ARB_fragment_program			X	X	X	
ARB_fragment_program_shadow			R55	X	X	
ARB_fragment_shader			R60	X	X	2.0 functionality, GLSL
ARB_half_float_pixel			R75	R75	X	
ARB_imaging	R10	X	X	X	X	1.2 imaging subset
ARB_multisample		X	X	X	X	1.3 functionality
ARB_multitexture	X	X	X	X	X	1.3 functionality
ARB_occlusion_query		R50	R50	R50	X	1.5 functionality
ARB_pixel_buffer_object	R80	R80	R80	R80	X	2.1 functionality

Key for table entries:

X = *supported*

Q = *requires particularly Quadro cards*

sw = *supported by software rasterization (expect poor performance)*

Nf = *Extension advertised but rendering functionality not available*

R10 = *introduced in the Release 10 OpenGL driver (not supported by earlier drivers)*

R20 = *introduced in the Detanator XP (also known as Release 20) OpenGL driver (not supported by earlier drivers)*

R20+ = *introduced after the Detanator XP (also known as Release 20) OpenGL driver (not supported by earlier drivers)*

R25 = *introduced in the GeForce4 launch (also known as Release 25) OpenGL driver (not supported by earlier drivers)*

R25+ = *introduced after the GeForce4 launch (also known as Release 25) OpenGL driver (not supported by earlier drivers)*

R35 = *post-GeForce4 launch OpenGL driver release (not supported by earlier drivers)*

R40 = Detonator 40 release, August 2002.

R40+ = *introduced after the Detanator 40 (also known as Release 40) OpenGL driver (not supported by earlier drivers)*

R50 = Detonator 50 release

R55 = Detonator 55 release

R60 = Detonator 60 release, May 2004

R65 = Release 65

R70 = Release 70

R80 = Release 80

R95 = Release 95

no spec = *no suitable specification available*

Discontinued = earlier drivers (noted by 25% gray entries) supported this extension but support for the extension is discontinued in current and future drivers

Notices:

Emulation: While disabled by default, older GPUs can support extensions supported in hardware by newer GPUs through a process called emulation though any functionality unsupported by the older GPU must be emulated via software. For more details see: http://developer.nvidia.com/object/nvemulate.html

Warning: The extension support columns are based on the latest & greatest NVIDIA driver release (unless otherwise noted). Check your GL_EXTENSIONS string with glGetString at run-time to determine the specific supported extensions for a particular driver version.

Discontinuation of support: NVIDIA drivers from release 95 no longer support NV1x- and NV2x-based GPUs.

Status

    Complete. Appprove by the ARB on October 22, 2004.

Version

    Based on the ATI_pixel_format_float extension, verion 5
    Enables based on work by Pat Brown from the color_clamp_control proposal

    Last Modified Date: February 7, 2006
    Version   6

Number

    ARB Extension #39

Dependencies

    This extension is written against the OpenGL 2.0 Specification
    but will work with the OpenGL 1.5 Specification.

    WGL_ARB_pixel_format is required.

    This extension interacts with ARB_fragment_program.

    This extension interacts with ARB_fragment_shader.

    This extension interacts with NV_float_buffer.

    This extension interacts with ATI_pixel_format_float.

Overview

    The standard OpenGL pipeline is based on a fixed-point pipeline.
    While color components are nominally floating-point values in the

pipeline, components are frequently clamped to the range [0,1] to accomodate the fixed-point color buffer representation and allow for fixed-point computational hardware.

This extension adds pixel formats or visuals with floating-point RGBA color components and controls for clamping of color components within the pipeline.

For a floating-point RGBA pixel format, the size of each float components is specified using the same attributes that are used for defining the size of fixed-point components. 32-bit floating-point components are in the standard IEEE float format. 16-bit floating-point components have 1 sign bit, 5 exponent bits, and 10 mantissa bits.

Clamping control provides a way to disable certain color clamps and allow programs, and the fixed-function pipeline, to deal in unclamped colors. There are controls to modify clamping of vertex colors, clamping of fragment colors throughout the pipeline, and for pixel return data.

The default state for fragment clamping is "FIXED_ONLY", which has the behavior of clamping colors for fixed-point color buffers and not clamping colors for floating-pont color buffers.

Vertex colors are clamped by default.

IP Status

SGI owns US Patent #6,650,327, issued November 18, 2003. SGI believes this patent contains necessary IP for graphics systems implementing floating point (FP) rasterization and FP framebuffer capabilities.

SGI will not grant the ARB royalty-free use of this IP for use in OpenGL, but will discuss licensing on RAND terms, on an individual basis with companies wishing to use this IP in the context of conformant OpenGL implementations. SGI does not plan to make any special exemption for open source implementations.

Contact Doug Crisman at SGI Legal for the complete IP disclosure.

Issues

1. *How is this extension different from the ATI_pixel_format_float extension?*

   RESOLVED: By default, this extension behaves like the ATI_pixel_format_float, but also adds additional controls for color clamping.

2. *Should the clamp controls be automatically inferred based on the format of the color buffer or textures used?*

   RESOLVED: Explicit controls should be supported -- this allows the use of floating-point buffers to emulate fixed-point operation, and allows for operating on unclamped values even when rendering to a fixed-point framebuffer.

However, a default clamping mode called "FIXED_ONLY" is defined that enables clamping only when rendering to a fixed-point color buffer, which is the default for fragment processing. This is done to maintain compatibility with previous extensions (ATI_pixel_format_float), and to allow applications to switch between fixed- and floating-point color buffers without having to change the clamping mode on each switch.

3. *How does the clamping control affect the blending equation?*

   RESOLVED: For fixed-point color buffers, the inputs and the result of the blending equation are clamped. For floating-point color buffers, no clamping occurs.

4. *Should the requirements for the representable range of color components be increased?*

   RESOLVED: No. Such a spec change would be complicated, since the required precision may vary based on color buffer precision. Despite the fact that there is no spec requirement, GL implementations should have at least as much precision/range in their colors as can be found in the framebuffer.

5. *Should the vertex color clamping control apply to RasterPos? WindowPos?*

   RESOLVED: Yes to both. RasterPos is processed just like a vertex, so the vertex color clamping control applies automatically. The WindowPos language in the OpenGL 2.0 specification explicitly refers to color clamping. Instead, we modify the language to perform normal processing, but with lighting forced off. This will result in the color clamping logic applying.

6. *What control should apply to DrawPixels RGBA components?*

   RESOLVED: The fragment color clamp control.

7. *Should this extension modify the clamping of the texture environment color components? TEXTURE_ENV_COLOR components are currently specified to be clamped to [0,1] when TexEnv is called.*

   RESOLVED: Yes. The texture environment color is no longer clamped when specified. If fragment color clamping is enabled, it will be clamped to [0,1] on use.

8. *In texture environment application, should color components used as an interpolation factor (e.g., alpha) be clamped to [0,1]?*

   RESOLVED: No. For interpolation-type blends, the weighting factor is normally in the range [0,1]. But the math is well-defined in the cases where it falls outside this range. When fragment color clamping is enabled, all sources are clamped to [0,1], so this is not an issue.

9. In the COMBINE texture environment mode, should any of the source argument operands be clamped to [0,1] even when fragment clamping is disabled? For example, ONE_MINUS_* mappings are simple in a fixed-point pipeline are simple, but more complicated in a floating-point one.

RESOLVED: No. The math behind ONE_MINUS_* is well-defined for all inputs.

10. Should the clamping controls affect the texture comparison mode for shadow mapping?

RESOLVED: No. The r coordinate should still be clamped to [0,1] to match the depth texture. The result of the comparison will naturally lie in the range [0,1].

11. Should the clamping controls affect the result of color sum?

RESOLVED: Yes.

12. Should the clamping controls affect the computed fog factor?

RESOLVED: No. The fog factor is not a color -- it is used to blend between the fragment color and the fog color. The factor should always be clamped to [0,1].

13. Should this extension modify the clamping of the fog color components? FOG_COLOR components are specified to be clamped to [0,1] when Fogfv is called.

RESOLVED: Yes. Fog color components are no longer clamped when specified, but will be clamped when fog is applied if fragment color clamping is enabled.

14. How does this extension interact with antialiasing application (Section 3.12 of the OpenGL 2.0 spec)?

RESOLVED: Multiply floating-point alpha by coverage, even if the alpha value is not being used as opacity. If applications don't want this multiplication, they should not render antialiased primitives. No spec language changes are needed here.

15. How does this extension interact with multisample point fade (Section 3.13 of the OpenGL 2.0 spec)?

RESOLVED: Multiply floating-point alpha by the fade factor, even if the alpha value is not being used as opacity. If applications don't want this multiplication, they should not use multisample point fade. No spec language changes are needed here.

16. *Should this extension modify the clamping of the alpha test reference value?*

    RESOLVED: Yes. The reference value is not clamped when specified, by may be clamped when it is used.

17. *Should this extension modify the clamping of the constant blend color components?*

    RESOLVED: Yes. The blend color is not clamped when specified. When rendering to a fixed-point framebuffer, the blend color will be clamped as part of the blending operation.

18. *Should this extension modify the clamping of clear colors?*

    RESOLVED: Yes. The clear color is not clamped when specified. When clearing color buffers, the clear color is converted to the format of the color buffer.

19. *Should we provide a control to disable implicit clamping of ReadPixels data? If so, how should it be specified?*

    RESOLVED: Yes. It is explicitely controlled by the target CLAMP_READ_COLOR_ARB of the ClampColorARB function and clamps the color during the final conversion.

20. *How does this extension interact with CopyPixels?*

    RESOLVED: It has no special interaction. CopyPixels is specified as roughly a ReadPixels/DrawPixels sequence, but the read color clamp modified by this specification occur during final conversion and therefore would not apply. The fragment color clamp does affect the DrawPixels portion of the operation, however. The net result is that calling CopyPixels with a floating-point framebuffer will clamp color components if fragment color clamping is enabled.

21. *Should these clamping controls interact with PushAttrib and PopAttrib? If so, what group should they belong to?*

    RESOLVED: For consistency, yes. Historically, all enables are pushed and popped with both the enable bit and a second bit corresponding to the function performed by the enable. The present spec calls for pushing the vertex color clamp with the lighting group and the fragment and read color clamp with the color-buffer group (for lack of a better choice).

22. *Should this extension require a floating-point color buffer or texture?*

    RESOLVED: No. This extension provides the ability to pass an unclamped color between vertex and fragment programs/shaders, which may be useful. This was possible prior to this extension, by passing the color data as texture coordinates or named varying variables (for vertex/fragment shaders).

23. *Does this extension interact with the ARB_vertex_program or ARB_vertex_shader extensions?*

    RESOLVED: Only in the most trivial way. Both of these extensions refer to the color clamping logic (Section 2.14.6 in the OpenGL 2.0 specification). This extension modifies that logic to be under control of the CLAMP_VERTEX_COLOR_ARB enable. It follows that this enable also controls the clamping of vertex program or vertex shader results.

24. *Does this extension interact with the ARB_fragment_program or ARB_fragment_shader extensions?*

    RESOLVED: Yes. The only interaction is that the fragment color clamp enable determines if the final color(s) produced by the fragment program/shader has its components clamped to [0,1].

    However, the fragment color clamp enable affects only the final result; it does NOT affect any computations performed during program execution. Note that the same clamping can be done explicitly in a fragment program or shader. ARB_fragment_program provides the "_SAT" opcode suffix to clamp instruction results to [0,1].

25. *Should this extension modify the clamping of the texture border color components?*

    RESOLVED: Not by this extension. See the ARB_texture_float extension.

26. *When using vertex and fragment programs/shaders, should color clamping be specified in the shader instead?*

    RESOLVED: No. All the existing program/shader extensions call for the color outputs to be clamped to [0,1], except that previous floating-point color buffer extensions disabled the clamp of fragment program/shader outputs.

    While it would be straightforward to have required that vertex or fragment programs manually clamp their outputs if desired, adding such a requirement at this point would pose compatibility issues. It would probably require introduction of a special directive to indicate that colors are unclamped.

    If a GL implementation internally performs color clamping in a vertex or fragment program, it may be necessary to recompile the program if the corresponding clamp enable changes.

27. *If certain colors in the OpenGL state vector were clamped in previous versions of the spec, but now have the clamping removed, do queries need to return clamped values for compatibility with older GL versions? Should we add new query tokens to return unclamped values?*

    RESOLVED: To minimize impact on this specification while allowing for compatibility with older GL versions, the values of the vertex/fragment color clamp enables should affect queries of such state. If the corresponding color clamp is enabled, components will be clamped to [0,1] when returned. Since color clamping is enabled by default for fixed-point color buffers, the removal of the clamps will not be observable by applications unless they disable one or both clamps or choose a floating-point buffer (which will not happen for "old" applications).

Note that this spec relaxes the clamp on the current raster color, but we don't need to add a clamp on the corresponding query. The current raster color is clamped when the GL computes it, unless vertex color clamping is disabled by the application.

28. *At what precision should alpha test be carried out? At the precision of the framebuffer? Or some other unspecified precision? What happens if you have a framebuffer with no alpha?*

RESOLVED: No specific precision requirements are added, except that the reference value used in the alpha test should be converted to the same precision and in the same manner as the fragment's alpha. This requirement is intended to avoid cases where the act of converting the alpha value of a fragment to fixed-point (or lower-precision floating-point) might change the result of the test.

29. *How does this extension interact with accumulation buffers?*

RESOLVED: This extension does not modify the nature of accumulation buffers. Adding semantics for floating-point accumulation buffers is left for a possible future extension. The clamp on the RETURN operation is controlled by the fragment color clamp enable.

30. *How does this extension interact with OpenGL FEEDBACK mode?*

RESOLVED: OpenGL FEEDBACK mode returns colors after clipping, which is done after the vertex color clamping. Therefore, the colors returned will be clamped to [0,1] if and only if vertex color clamping is enabled. No spec language changes are necessary.

31. *Should we relax the language in Section 2.14.9 (Final Color Processing) to not require conversion to fixed-point?*

RESOLVED: Adding floating-point vertex colors requires that this language be modified. Even for the clamped case, it seems reasonable for implementations to simply clamp a floating-point value to [0,1] without converting to a fixed-point representation. This specification makes converting colors to fixed-point optional. Colors will obviously still be converted to fixed-point eventually if the framebuffer is fixed-point.

32. *What should be done about the "preserving the bits" requirement for Color*{ub,us,ui} commands in Section 2.14.9?*

RESOLVED: If colors are represented as floats internally and the frame-buffer is fixed-point, do we require that the MSBs of fixed-point colors that don't go through lighting, and non-trivial interpolation, or any non-trivial fragment operations show up in the MSBs of the framebuffer?

33. *How does this extension interact with multisample ALPHA_TO_COVERAGE, where an alpha value expected to be in the range [0,1] is turned into a set of coverage bits?*

    UNRESOLVED: For the purposes of generating sample coverage from fragment alpha, the alpha values are effectively clamped to [0,1]. Negative alpha values correspond to no coverage; alpha values greater than one correspond to full coverage.

34. *What happens if there are no color buffers in the framebuffer and a clamp control is set to FIXED_ONLY?*

    RESOLVED: The present language treats a zero-bit color buffer as fixed-point.

35. *Should the clamping of fragment shader output gl_FragData[n] be controlled by the fragment color clamp.*

    RESOLVED: Since the destination of the FragData is a color buffer, the fragment color clamp control should apply.

36. *Should logical operations be disabled for floating-point color buffers.*

    RESOLVED: Yes. This matches the behavior in the ATI specification.

37. *Is it expected that a floating-point color read from a floating-point color buffer exactly match a floating-point color in a fragment? Will the alpha test of GL_EQUAL be expected to work?*

    RESOLVED: This behavior is not required by this extension. Floating-point data may have different precision at different parts of the pipeline.

38. *How does this extension handle the case where a floating-point and a fixed-point buffer exists?*

    RESOLVED: For vertex colors, clamping occurs if any color buffer are floating point. Fragment colors are handled based on the format (fixed or float) of the color buffer that they will be drawn to.

New Procedures and Functions

```
    void ClampColorARB(enum target, enum clamp);
```

New Tokens

```
    Accepted by the <pname> parameters of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

        RGBA_FLOAT_MODE_ARB                         0x8820

    Accepted by the <target> parameter of ClampColorARB and the <pname>
    parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev.

        CLAMP_VERTEX_COLOR_ARB                      0x891A
        CLAMP_FRAGMENT_COLOR_ARB                    0x891B
        CLAMP_READ_COLOR_ARB                        0x891C

    Accepted by the <clamp> parameter of ClampColorARB.

        FIXED_ONLY_ARB                              0x891D
        FALSE
        TRUE

    Accepted as a value in the <piAttribIList> and <pfAttribFList>
    parameter arrays of wglChoosePixelFormatARB, and returned in the
    <piValues> parameter array of wglGetPixelFormatAttribivARB, and the
    <pfValues> parameter array of wglGetPixelFormatAttribfvARB:

        WGL_TYPE_RGBA_FLOAT_ARB                     0x21A0

    Accepted as values of the <render_type> arguments in the
    glXCreateNewContext and glXCreateContext functions

        GLX_RGBA_FLOAT_TYPE                         0x20B9

    Accepted as a bit set in the GLX_RENDER_TYPE variable

        GLX_RGBA_FLOAT_BIT                          0x00000004
```

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

```
    Add a new Section 2.1.2, (p. 6):
```

2.1.2 16-Bit Floating-Point Numbers

```
    A 16-bit floating-point number has a 1-bit sign (S), a 5-bit
    exponent (E), and a 10-bit mantissa (M).  The value of a 16-bit
    floating-point number is determined by the following:

        (-1)^S * 0.0,                        if E == 0 and M == 0,
        (-1)^S * 2^-14 * (M / 2^10),         if E == 0 and M != 0,
        (-1)^S * 2^(E-15) * (1 + M/2^10),    if 0 < E < 31,
        (-1)^S * INF,                        if E == 31 and M == 0, or
        NaN,                                 if E == 31 and M != 0,

    where

        S = floor((N mod 65536) / 32768),
        E = floor((N mod 32768) / 1024), and
        M = N mod 1024.
```

Implementations are also allowed to use any of the following alternative encodings:

```
    (-1)^S * 0.0,                        if E == 0 and M != 0,
    (-1)^S * 2^(E-15) * (1 + M/2^10),    if E == 31 and M == 0, or
    (-1)^S * 2^(E-15) * (1 + M/2^10),    if E == 31 and M != 0,
```

Any representable 16-bit floating-point value is legal as input to a GL command that accepts 16-bit floating-point data. The result of providing a value that is not a floating-point number (such as infinity or NaN) to such a command is unspecified, but must not lead to GL interruption or termination. Providing a denormalized number or negative zero to GL must yield predictable results.

Modify Section 2.13 (Current Raster Position), p. 54

(modify last paragraph on p. 55) Lighting, texture coordinate generation and transformation, and clipping are not performed by the WindowPos functions. Instead, in RGBA mode, the current raster color and secondary color are obtained from the current color and secondary color, respectively. If vertex color clamping is enable, the current raster color and secondary color are clamped to [0, 1]. In color index mode, the current raster color index is set to the current color index. The current raster texture coordinates are set to the current texture coordinates, and the valid bit is set.

Modify Section 2.14 (Colors and Coloring), p. 57

(modify last paragraph on p.57) ... After lighting, RGBA colors are optionally clamped to the range [0,1]. ...

Modify Section 2.14.6 (Clamping or Masking), p. 69

(modify first and second paragraphs of section) When the GL is in RGBA mode and vertex color clamping is enabled, all components of both primary and secondary colors are clamped to the range [0,1] after lighting. If color clamping is disabled, the primary and secondary colors are unmodified. Vertex color clamping is controlled by calling

```
    void ClampColorARB(enum target, enum clamp)
```

with a <target> set to CLAMP_VERTEX_COLOR_ARB. If <clamp> is TRUE, vertex color clamping is enabled; if <clamp> is FALSE, vertex color clamping is disabled. If <clamp> is FIXED_ONLY_ARB, vertex color clamping is enabled if all enabled color buffers have fixed-point components.

For a color index, the index is first converted to...

(add paragraph at the end of the section) The state required for color clamping is an enumerant. Vertex color clamping is initially TRUE.

Replace Section 2.14.9 (Final Color Processing), p. 71

In RGBA mode with vertex color clamping disabled, the floating-point RGBA components are not modified.

In RGBA mode with vertex clamping enabled, each color component (already clamped to [0,1]) may be converted (by rounding to nearest) to a fixed-point value with m bits. We assume that the fixed-point representation used represents each value k/(2^m - 1), with k in the set {0, 1, . . . , 2^m - 1}, as k (e.g. 1.0 is represented in binary as a string of all ones). m must be at least as large as the number of bits in the corresponding component of the framebuffer. m must be at least 2 for A if the framebuffer does not contain an A component, or if there is only 1 bit of A in the framebuffer. GL implementations are not required to convert clamped color components to fixed-point.

Because a number of the form k/(2^m - 1) may not be represented exactly as a limited-precision floating-point quantity, we place a further requirement on the fixed-point conversion of RGBA components. Suppose that lighting is disabled, the color associated with a vertex has not been clipped, and one of Colorub, Colorus, or Colorui was used to specify that color. When these conditions are satisfied, an RGBA component must convert to a value that matches the component as specified in the Color command: if m is less than the number of bits b with which the component was specified, then the converted value must equal the most significant m bits of the specified value; otherwise, the most significant b bits of the converted value must equal the specified value.

In color index mode, a color index is converted (by rounding to nearest) to a fixed-point value with at least as many bits as there are in the color index portion of the framebuffer.

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

Modify Section 3.6.4 (Rasterization of Pixel Rectangles), p. 126

(modify next-to-last paragraph, p.136, "Final Conversion") ... For RGBA components, if fragment color clamping is enabled, each element is clamped to [0,1], and may be converted to fixed-point according to the rules given in section 2.14.9 (Final Color Processing). If fragment color clamping is disabled, RGBA components are unmodified. Fragment color clamping is controlled using ClampColorARB, as described in section 2.14.6, with a <target> of CLAMP_FRAGMENT_COLOR_ARB.

(add new paragraph at the end of "Final Conversion", p.137) The state required for fragment color clamping is an enumerant. Fragment color clamping is initially set to FIXED_ONLY_ARB.

Modify Section 3.8.13 (Texture Environments and Functions), p.182

(modify third paragraph, p. 183, removing clamping language) ...TEXTURE_ENV_COLOR is set to an RGBA color by providing four single-precision floating-point values. If integers are provided for TEXTURE ENV COLOR, then they are converted to floating-point as specified in table 2.9 for signed integers.

(replace the sixth paragraph of p. 183) If fragment color clamping is enabled, all of these color values, including the results, are clamped to the range [0,1]. If fragment color clamping is disabled, the values are not clamped. The texture functions are specified in tables 3.22, 3.23, and 3.24.

(modify seventh paragraph of p. 183) ... ALPHA_SCALE, respectively. If fragment color clamping is enabled, the arguments and results used in table 3.24 are clamped to [0,1]. Otherwise, the results are unmodified.

Modify Section 3.9 (Color Sum), p. 191

(modify second paragraph) ... the A component of c_sec is unused. If color sum is disabled, then c_pri is assigned to c. The components of c are then clamped to the range [0,1] if and only if fragment color clamping is enabled.

Modify Section 3.10 (Fog), p. 191

(modify fourth paragraph, p. 192, removing clamping language) ...If these are not floating-point values, then they are converted to floating-point using the conversion given in table 2.9 for signed integers. If fragment color clamping is enabled, the components of C_r and C_f and the result C are clamped to the range [0,1] before the fog blend is performed.

Modify Section 3.11.2 (Shader Execution), p. 194

(modify Shader Inputs, first paragraph, p. 196) The built-in variables gl_Color and gl_SecondaryColor hold the R, G, B, and A components, respectively, of the fragment color and secondary color. If the primary color or the secondary color components are represented by the GL as fixed-point values, they undergo an implied conversion to floating-point. This conversion must leave the values 0 and 1 invariant. Floating-point color components (resulting from a disabled vertex color clamp) are unmodified.

(modify Shader Outputs, first paragraph, p. 196) ... These are gl_FragColor, gl_FragData[n], and gl_FragDepth. If fragment clamping is enabled, the final fragment color values or the final fragment data values written by a fragment shader are clamped to the range [0, 1] and then may be converted to fixed-point as described in section 2.14.9. If fragment clamping is disabled, the final fragment color values or the final fragment data values are not modified. The final fragment depth...

Additions to Chapter 4 of the OpenGL 2.0 Specification (Per-Fragment Operations and the Framebuffer)

Modify Chapter 4 Introduction, (p. 198)

(modify third paragraph, p. 198) Color buffers consist of either unsigned integer color indices, R, G, B and optionally A unsigned integer values, or R, G, B, and optionally A floating-point values. The number of bitplanes...

Modify Section 4.1.3 (Multisample Fragment Operations), p. 200

(modify last paragraph, p. 200) ...and all 0's corresponding to all alpha values being 0. The alpha values used to generate a coverage value are clamped to the range [0,1]. It is also intended ...

Modify Section 4.1.5 (Alpha Test), p. 201

(modify first paragraph of section, deleting clamping of reference value) ... The test is controlled with

```
   void AlphaFunc(enum func, float ref);
```

func is a symbolic constant indicating the alpha test function; ref is a reference value. When performing the alpha test, the GL will convert the reference value to the same representation as the the fragment's alpha value (floating-point or fixed-point). For fixed-point, the reference value is converted according to the rules given for an A component in section 2.14.9 and the fragment's alpha value is rounded to the nearest integer. The possible ...

Modify Section 4.1.8 (Blending), p. 205

(modify first paragraph, p. 206) Source and destination values are combined according to the blend equation, quadruplets of source and destination weighting factors determined by the blend functions, and a constant blend color to obtain a new set of R, G, B, and A values, as described below.

If the color buffer is fixed-point, the components of the source and destination values and blend factors are clamped to [0, 1] prior to evaluating the blend equation, the components of the blending result are clamped to [0,1] and converted to fixed-point values in the manner described in section 2.14.9. If the color buffer is floating-point, no clamping occurs. The resulting four values are sent to the next operation.

(modify fifth paragraph, p. 206) Fixed-point destination (framebuffer) components are taken to be fixed-point values represented according to the scheme given in section 2.14.9 (Final Color Processing). Constant color components, floating-point destination components, and source (fragment) components are taken to be floating point values. If source components are represented internally by the GL as either fixed-point values they are also interepreted according to section 2.14.9.

(modify Blend Color section removing the clamp, p. 209) The constant color C_c to be used in blending is specified with the command

```
   void BlendColor(float red, float green, float blue, float alpha);
```

The constant color can be used in both the source and destination blending functions.

Replace Section 4.1.9 (Dithering), p. 209

Dithering selects between two representable color values or indices. A representable value is a value that has an exact representation in the color buffer. In RGBA mode dithering selects, for each color component, either the most positive representable color value (for that particular color component) that is less than or equal to the incoming color component value, c, or the most negative representable color value that is greater than or equal to c. The selection may depend on the x_w and y_w coordinates of the pixel, as well as on the exact value of c. If one of the two values does not exist, then the selection defaults to the other value.

In color index mode dithering selects either the largest representable index that is less than or equal to the incoming color value, c, or the smallest representable index that is greater than or equal to c. If one of the two indices does not exist, then the selection defaults to the other value.

Many dithering selection algorithms are possible, but an individual selection must depend only on the incoming color index or component value and the fragment's x and y window coordinates. If dithering is disabled, then each incoming color component c is replaced with the most positive representable color value (for that particular component) that is less than or equal to c, or by the most negative representable value, if no representable value is less than or equal to c; a color index is rounded to the nearest representable index value.

Dithering is enabled with Enable and disabled with Disable using the symbolic constant DITHER. The state required is thus a single bit. Initially dithering is enabled.

Section 4.1.10 (Logical Operation), p. 210

(insert after the first sentence, p. 210) Logical operation has no effect on a floating-point destination color buffer. However, if COLOR_LOGIC_OP is enabled, blending is still disabled.

Modify Section 4.2.3 (Clearing the Buffers), p. 215

(modify second paragraph, p. 216, removing clamp of clear color)

```
   void ClearColor(float r, float g, float b, float a);
```

sets the clear value for the color buffers in RGBA mode.

(add to the end of first partial paragraph, p. 217) ... then a Clear directed at that buffer has no effect. Fixed-point RGBA color buffers are cleared to a color values derived by taking the clear color, clamping to [0,1], and converting to fixed-point according to the rules of section 2.14.9.

Modify Section 4.2.4 (The Accumulation Buffer), p. 217

(modify second paragraph in section, p. 217) ... Using ACCUM obtains R, G, B, and A components from the color buffer currently selected for reading (section 4.3.2). If the color buffer is fixed-point, each component is considered as a fixed-point value in [0,1] (see section 2.14.9) and is converted to floating-point. Each result is then multiplied ...

(modify second paragraph on p. 218) The RETURN operation takes each color value from the accumulation buffer and multiplies each of the R, G, B, and A components by <value>. If fragment color clamping is enabled, the results are then clamped to the range [0,1]. ...

Modify Section 4.3.2 (Reading Pixels), p. 219

(modify paragraph at top of page, p. 222) ... For a fixed-point color buffer, each element is taken to be a fixed-point value in [0, 1] with m bits, where m is the number of bits in the corresponding color component of the selected buffer (see section 2.14.9). For floating-point color buffer, the elements are unmodified.

(modify second paragraph of "Final Conversion", p. 222) For an RGBA color, if <type> is not FLOAT, or if the CLAMP_READ_COLOR_ARB is TRUE, or CLAMP_READ_COLOR_ARB is FIXED_ONLY_ARB and the selected color buffer is a fixed-point buffer, each component is first clamped to [0,1]. Then the appropriate conversion...

Additions to Chapter 5 of the OpenGL 2.0 Specification (Special Functions)

None

Additions to Chapter 6 of the OpenGL 2.0 Specification (State and State Requests)

Modify Section 6.1.2, Data Conversions, p. 245

(add new paragraph at the end of the section, p. 245) If fragment color clamping is enabled, querying of the texture border color, texture environment color, fog color, alpha test reference value, blend color, and RGBA clear color will clamp the corresponding state values to [0,1] before returning them. This behavior provides compatibility with previous versions of the GL that clamped these values when specified.

Additions to Chapter 1 of the GLX 1.3 Specification (Overview)

None

Additions to Chapter 2 of the GLX 1.3 Specification (GLX Operation)

None

Additions to Chapter 3 of the GLX 1.3 Specification (Functions and Errors)

Replace Section 3.3.3 (p.12) Paragraph 4 to:

The attribute GLX_RENDER_TYPE has as its value a mask indicating what type of GLXContext a drawable created with the corresponding GLXFBConfig can be bound to. The following bit settings are supported: GLX_RGBA_BIT, GLX_RGBA_FOAT_BIT, GLX_COLOR_INDEX_BIT. If combinations of bits are set in the mask then drawables created with the GLXFBConfig can be bound to those corresponding types of rendering contexts.

Add to Section 3.3.3 (p.15) after first paragraph:

Note that floating point rendering is only supported for GLXPbuffer drawables. The GLX_DRAWABLE_TYPE attribute of the GLXFBConfig must have the GLX_PBUFFER_BIT bit set and the GLX_RENDER_TYPE attribute must have the GLX_RGBA_FLOAT_BIT set.

Modify Section 3.3.7 (p.25 Rendering Contexts) remove period at end of second paragraph and replace with:

; if render_type is set to GLX_RGBA_FLOAT_TYPE then a context that supports floating point RGBA rendering is created.

Additions to Chapter 4 of the GLX 1.3 Specification (Encoding on the X Byte Stream)

None

Additions to Chapter 5 of the GLX 1.3 Specification (Extending OpenGL)

None

Additions to Chapter 6 of the GLX 1.3 Specification (GLX Versions)

None

Additions to Chapter 7 of the GLX 1.3 Specification (Glossary)

None

Additions to the GLX Specification

Modify the bit field GLX_RENDER_TYPE to:

GLX_RENDER_TYPE
The type of pixel data. This bit field can have the following bit set: GLX_RGBA_BIT, GLX_RGBA_FLOAT_BIT, GLX_COLOR_INDEX_BIT

```
    Adds to the accepted values of the <render_type> argument
    in the glXCreateNewContext and glXCreateContextWithSGIX
    functions to:

    <render_type>
    Type of rendering context requested.  This argument
    can have the following values: GLX_RGBA_TYPE,
    GLX_RGBA_FLOAT_TYPE, GLX_COLOR_INDEX_TYPE
```

GLX Protocol

```
    The following rendering commands are sent to the server as part
    of a glXRender request:

    ClampColorARB
        2           12              rendering command length
        2           234             rendering command opcode
        4           CARD32          target
        4           CARD32          clamp
```

Additions to the WGL Specification

```
    Modify the values accepted by WGL_PIXEL_TYPE_ARB to:

        WGL_PIXEL_TYPE_ARB
        The type of pixel data. This can be set to WGL_TYPE_RGBA_ARB,
        WGL_TYPE_RGBA_FLOAT_ARB, or WGL_TYPE_COLORINDEX_ARB.
```

Dependencies on WGL_ARB_pixel_format

```
    The WGL_ARB_pixel_format extension must be used to determine a
    pixel format with float components.
```

Dependencies on ARB_fragment_program

```
    (modify 2nd paragraph of Section 3.11.4.4 language) If fragment
    color clamping is enabled, the fragment's color components are first
    clamped to the range [0,1] and are optionally converted to fixed
    point as in section 2.14.9.  If the fragment program does not write
    result.color, the color will be undefined in subsequent stages.
```

Dependencies on ARB_fragment_shader

```
    (modify 1st paragraph of Section 3.11.6 language) ... are
    gl_FragColor and gl_FragDepth.  If fragment color clamping is
    enabled, the final fragment color values written by a fragment
    shader are clamped to the range [0,1] and are optionally converted
    to fixed-point as described in section 2.14.9, Final Color
    Processing.  ...
```

Dependencies on NV_float_buffer

```
    Note that the WGL/GLX enumerants for the NV and ARB extensions
    do not have the same values, so it is possible to distinguish
    between "NV" and "ARB" pixel formats.
```

If NV_float_buffer and ARB_color_buffer_float are both supported, restrictions imposed by NV_float_buffer are removed. In particular, antialiasing application, multisample fragment operations, alpha test, and blending are all performed as specified in this extension. Additionally, it is not necessary to use a fragment program or shader to render to a floating-point color buffer allocated using the NV_float_buffer extension.

Note also that vertex color clamp portion of this extension does not interact with NV_float_buffer.

Dependencies on ATI_pixel_format_float

The basic policy of ATI_pixel_format_float regarding clamping is that vertex color clamping is unaffected (still enabled) and that fragment color clamping is automatically disabled when rendering to floating-point color buffers.

This extension is designed so that the defaults are compatible with the ATI_pixel_format_float, so there is no need for separate "ATI" and "ARB" floating-point pixel formats.

Errors

Revision History

Rev.	Date	Author	Changes
1	2/26/04	Kirkland	Initial version based on the ATI extension.

2	3/11/04	Kirkland	Changed spec to be both a GL and WGL spec. Updated language for float16 number handling. Added bit encodings for half values. Removed the clamped color query. Updated the language for dithering.
3	7/23/04	Kirkland	Added alternative encodings options for float16 format.
4	9/17/04	Kirkland	Merged the color clamp control spec with this spec. Updated to reference the OpenGL 2.0 spec. Added the specification for GLX.
5	10/1/04	Kirkland	Updated IP section. Reviewed by the ARB and closed all UNRESOLVED issues. Added an invariant that discusses the handling of the alpha test.
6	2/6/07	Jon Leech	Fix typos in enum naming.

Name

ARB_depth_texture

Name Strings

GL_ARB_depth_texture

Status

Complete. Approved by ARB on February 14, 2002.

Version

Last Modified Date: 13 May 2004

Number

ARB Extension #22

Dependencies

OpenGL 1.1 is required.
This extension is written against the OpenGL 1.3 Specification.

Overview

This is a clarification of the GL_SGIX_depth_texture extension. The original overview follows:

This extension defines a new depth texture format. An important application of depth texture images is shadow casting, but separating this from the shadow extension allows for the potential use of depth textures in other applications such as image-based rendering or displacement mapping. This extension does not define new depth-texture environment functions, such as filtering or applying the depth values computed from a texture but leaves this to other extensions, such as the shadow extension.

IP Status

None.

Issues

(1) How is this extension different from GL_SGIX_depth_texture?

This extension defines support for texture border values, querying depth texel resolution, and behavior when a depth texture is bound to a texture unit that's expecting RGBA texels.

(2) What about texture borders and the border value?

Texture borders are supported. The texture border value used for depth textures is the first component of TEXTURE_BORDER_COLOR.

(3) What happens when a depth texture is currently bound but RGBA texels are expected by the texture unit?

The depth texture is treated as if it were a LUMINANCE texture. It's sometimes useful to render a depth component texture as a grayscale texture.

(4) What happens when an RGBA texture is currently bound but depth texels are expected by the texture unit?

We do texturing in the normal way for an RGBA texture.

(5) What about 1D, 3D and cube maps textures? Should depth textures be supported?

RESOLVED: For 1D textures, yes, for orthogonality. For 3D and cube map textures, no. In both cases, the R coordinate that would be ordinarily be used for a shadow comparison is needed for texture lookup and won't contain a useful value. In theory, the shadow functionality could be extended to provide useful behavior for such targets, but this enhancement is left to a future extension.

(6) Why "depth" textures instead of a generic, extended-precision, single-channel texture format?

RESOLVED: We need a depth format so that glCopyTex[Sub]Image() can copy data from the depth buffer to the texture memory.

(7) Is there any particular reason that depth textures should only be used as LUMINANCE textures?

RESOLVED: Add DEPTH_TEXTURE_MODE to allow depth textures to be used as LUMINANCE, INTENSITY or ALPHA textures.

(8) It is very unlikely that depth textures when used as LUMINANCE, INTENSITY or ALPHA textures are used at their full storage precision. Should there be a query for the actual number of bits used for depth textures?

RESOLVED: No. OpenGL does not have queries for internal precision. Instead of adding it randomly for one feature, it should be looked in the broader context of providing it for more features.

(9) How should GetTexImage work for depth textures?

RESOLVED: Since GetTexImage is modeled on ReadPixels, reading depth components should require the DEPTH_COMPONENT format. Specifying a color format when querying a texture image with a DEPTH_COMPONENT base internal format should be an invalid operation. Likewise, specifying a DEPTH_COMPONENT format when querying a texture image with a color internal format should be an invalid operation. This is not only consistent with ReadPixels but how the EXT_paletted_texture and NV_texture_shader extensions amend GetTexImage to return non-color texture image data.

New Procedures and Functions

    None

New Tokens

    Accepted by the <internalFormat> parameter of TexImage1D, TexImage2D,
    CopyTexImage1D and CopyTexImage2D:

```
    DEPTH_COMPONENT
    DEPTH_COMPONENT16_ARB       0x81A5  (same as DEPTH_COMPONENT16_SGIX)
    DEPTH_COMPONENT24_ARB       0x81A6  (same as DEPTH_COMPONENT24_SGIX)
    DEPTH_COMPONENT32_ARB       0x81A7  (same as DEPTH_COMPONENT32_SGIX)
```

    Accepted by the <format> parameter of GetTexImage, TexImage1D,
    TexImage2D, TexSubImage1D, and TexSubImage2D:

```
    DEPTH_COMPONENT
```

    Accepted by the <pname> parameter of GetTexLevelParameterfv and
    GetTexLevelParameteriv:

```
    TEXTURE_DEPTH_SIZE_ARB      0x884A
```

    Accepted by the <pname> parameter of TexParameterf, TexParameteri,
    TexParameterfv, TexParameteriv, GetTexParameterfv, and GetTexParameteriv:

```
    DEPTH_TEXTURE_MODE_ARB      0x884B
```

Additions to Chapter 2 of the 1.3 Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the 1.3 Specification (Rasterization)

    Section 3.8.1, Texture Image Specification, p. 116, change last
    sentence of first paragraph to:

        "The format STENCIL_INDEX is not allowed."

    Section 3.8.1, Texture Image Specification, p. 116, change final
    paragraph to read:

        "The selected groups are processed exactly as for DrawPixels, stopping
        just before final conversion. Each R, G, B, A or depth component (D)
        value so generated is clamped to [0,1]."

    Section 3.8.1, Texture Image Specification, p. 117, modify beginning of
    the first paragraph:

        "Components are then selected from the resulting R, G, B, A, or D
        values to obtain a texture with the base internal format specified
        by..."

Section 3.8.1, Texture Image Specification, p. 117, add two new paragraphs after the beginning of the first paragraph:

"Textures with a base internal format of DEPTH_COMPONENT are supported by texture image specification commands only if <target> is TEXTURE_1D, TEXTURE_2D, PROXY_TEXTURE_1D or PROXY_TEXTURE_2D. Using this format in conjunction with any other <target> will result in an INVALID_OPERATION error."

"Textures with a base internal format of DEPTH_COMPONENT require depth component data; textures with other base internal formats require RGBA component data. The error INVALID_OPERATION is generated if the base internal format is DEPTH_COMPONENT and format is not DEPTH_COMPONENT, or if the base internal format is not DEPTH_COMPONENT and format is DEPTH_COMPONENT."

Section 3.8.1, Texture Image Specification, p. 117, modify the last paragraph, which flows to p. 118:

"... If a sized internal format is specified, the mapping of the R, G, B, A, and D values to texture components is equivalent to ..."

(on p. 118) "... If a compressed internal format is specified, the mapping of the R, G, B, A, and D values to texture components is equivalent to..."

Section 3.8.1, Texture Image Specification, p. 118, add a new row to Table 3.15.

Base Internal Format	RGBA Values	Internal Components
DEPTH_COMPONENT	D	D

Section 3.8.1, Texture Image Specification, p. 118, add three new rows and one new column to Table 3.16.

Sized Internal Format	Base Int. Format	...	D bits
DEPTH_COMPONENT16_ARB	DEPTH_COMPONENT		16
DEPTH_COMPONENT24_ARB	DEPTH_COMPONENT		24
DEPTH_COMPONENT32_ARB	DEPTH_COMPONENT		32

Section 3.8.2, Alternate Texture Image Specification Commands, p. 125, modify first paragraph to read:

... "The image is taken from the framebuffer exactly as if these arguments were passed to CopyPixels, with argument <type> set to COLOR or DEPTH_COMPONENT, depending on <internalformat>, stopping after pixel transfer processing is complete. RGBA data is taken from the current color buffer while depth component data is taken from the depth buffer. If no depth buffer is present, the error INVALID_OPERATION is generated. Subsequent processing is identical to that described for TexImage2D, beginning with clamping of the R, G, B, A, or depth values from the resulting pixel groups." ...

    Section 3.8.4, Texture Parameters, p. 133, append table 3.19 with the
    following:

Name	Type	Legal Values
DEPTH_TEXTURE_MODE_ARB	enum	LUMINANCE, INTENSITY, ALPHA

    Before current section 3.8.5, Texture Wrap Modes, p. 134, insert the
    following new section. Renumber subsections of 3.8 appropriately.

        "3.8.5 Depth Component Textures

        Depth textures can be treated as LUMINANCE, INTENSITY or ALPHA
        textures during texture filtering and application. Initially,
        depth textures are interpreted as LUMINANCE."

    Modify section 3.8.7, Texture Minification, p. 139. Modify the last
    paragraph before the "Mipmapping" section to read:

        "If any of the selected tauijk, tauij, or taui in the above
        equations refer to a border texel with i < -bs, j < bs, k < -bs,
         i >= ws-bs, j >= hs-bs, or k >= ds-bs, then the border values
        given by the current setting of TEXTURE_BORDER_COLOR is used
        instead of the unspecified value or values. If the texture
        contains color components, the components of the
        TEXTURE_BORDER_COLOR vector are interpreted as an RGBA color
        to match the texture's internal format in a manner consistent
        with table 3.15. If the texture contains depth components,
        the R component of the TEXTURE_BORDER_COLOR vector is
        interpreted as the depth component value."

Additions to Chapter 4 of the 1.3 Specification (Per-Fragment Operations and the Frame Buffer)

    None

Additions to Chapter 5 of the 1.3 Specification (Special Functions)

    None

Additions to Chapter 6 of the 1.3 Specification (State and State Requests)

    Section 6.1.3, Enumerated Queries, p. 200, edit paragraph two as follows:

        ..."Queries of TEXTURE_RED_SIZE, TEXTURE_GREEN_SIZE,
        TEXTURE_BLUE_SIZE, TEXTURE_ALPHA_SIZE, TEXTURE_LUMINANCE_SIZE,
        TEXTURE_INTENSITY_SIZE, and TEXTURE_DEPTH_SIZE_ARB return the
        actual resolutions of the stored image array components, not
        the resolutions specified when the image array was defined.

    Section 6.1.4, Texture Queries, p. 201, replace the sentence two of
    paragraph two as follows:

        "Calling GetTexImage with a color format when the internal
        format of the texture image is not a color format causes the error
        INVALID_OPERATION. Likewise, calling GetTexImage with a format
        of GL_DEPTH_COMPONENT when the internal format of the texture

        image is not a depth format cause the error INVALID_OPERATION.
        If the internal format of the texture image level is a color
        format (one of RED, GREEN, BLUE, ALPHA, RGB, RGBA, LUMINANCE, or
        LUMINANCE_ALPHA), then the components are assigned among R, G,
        B, and A according to Table 6.1, starting with the first group
        in the first row, and continuing by obtaining groups in order
        from each row and proceeding from the first row to the last, and
        from the first image to the last for three-dimensional textures.
        If the internal format of the texture image level is a depth
        format (DEPTH_COMPONENT), then each depth component is assigned
        with the same ordering of rows and images."

Replace the last sentence of paragraph four with:

"Calling GetTexImage with format of COLOR_INDEX or STENCIL_INDEX causes the error INVALID_ENUM."

Section 1.6.7, Color Table Query, p.203, replace sentence two of paragraph one with:

"format and type accept the same values as do the corresponding parameters of GetTexImage except that a format of DEPTH_COMPONENT causes the error INVALID_ENUM."

Section 1.6.8, Convolution Query, p.204, replace sentence two of paragraph one with:

"format and type accept the same values as do the corresponding parameters of GetTexImage except that a format of DEPTH_COMPONENT causes the error INVALID_ENUM."

Section 1.6.9, Histogram Query, p.205, replace sentence two of paragraph one with:

"format and type accept the same values as do the corresponding parameters of GetTexImage except that a format of DEPTH_COMPONENT causes the error INVALID_ENUM."

Section 1.6.10, Minmax Query, p.205, replace sentence two of paragraph one with:

"format and type accept the same values as do the corresponding parameters of GetTexImage except that a format of DEPTH_COMPONENT causes the error INVALID_ENUM."

Additions to the GLX Specification

None

Errors

INVALID_OPERATION is generated by TexImage2D or CopyTexImage2D if <target> is not TEXTURE_2D or PROXY_TEXTURE_2D and <internalFormat> is DEPTH_COMPONENT, DEPTH_COMPONENT16_ARB, DEPTH_COMPONENT24_ARB, or DEPTH_COMPONENT32_ARB.

```
    INVALID_OPERATION is generated by TexImage1D or CopyTexImage1D if
    <target> is not TEXTURE_1D or PROXY_TEXTURE_1D and <internalFormat>
    is DEPTH_COMPONENT, DEPTH_COMPONENT16_ARB, DEPTH_COMPONENT24_ARB, or
    DEPTH_COMPONENT32_ARB.

    INVALID_OPERATION is generated by TexImage1D or TexImage2D if <format>
    is DEPTH_COMPONENT and <internalFormat> is not DEPTH_COMPONENT,
    DEPTH_COMPONENT16_ARB, DEPTH_COMPONENT24_ARB, or DEPTH_COMPONENT32_ARB.

    INVALID_OPERATION is generated by TexImage1D or TexImage2D if
    <internalFormat> is DEPTH_COMPONENT, DEPTH_COMPONENT16_ARB,
    DEPTH_COMPONENT24_ARB, or DEPTH_COMPONENT32_ARB, and <format> is not
    DEPTH_COMPONENT.

    INVALID_OPERATION is generated by TexSubImage1D or TexSubImage2D if
    <format> is DEPTH_COMPONENT and the base internal format of the
    texture is not DEPTH_COMPONENT, DEPTH_COMPONENT16_ARB,
    DEPTH_COMPONENT24_ARB, or DEPTH_COMPONENT32_ARB.

    INVALID_OPERATION is generated by TexSubImage1D or TexSubImage2D if
    <format> is not DEPTH_COMPONENT and the base internal format of
    the texture is DEPTH_COMPONENT, DEPTH_COMPONENT16_ARB,
    DEPTH_COMPONENT24_ARB, or DEPTH_COMPONENT32_ARB.

    INVALID_OPERATION is generated by TexImage3D if <internalFormat>
    is DEPTH_COMPONENT, DEPTH_COMPONENT16_ARB, DEPTH_COMPONENT24_ARB,
    or DEPTH_COMPONENT32_ARB.

    INVALID_OPERATION is generated by CopyTexImage1D or CopyTexImage2D if
    <internalFormat> is DEPTH_COMPONENT, DEPTH_COMPONENT16_ARB,
    DEPTH_COMPONENT24_ARB, or DEPTH_COMPONENT32_ARB, and there is no depth
    buffer.

    INVALID_OPERATION is generated by CopyTexSubImage1D or CopyTexSubImage2D
    if the base internal format of the texture is DEPTH_COMPONENT and there
    is no depth buffer.

    INVALID_ENUM is generated if TexParameter[if] parameter <pname>
    is DEPTH_TEXTURE_MODE_ARB and parameter <param> is not ALPHA,
    LUMINANCE, or INTENSITY.

    INVALID_OPERATION is generated if GetTexImage parameter <format>
    is one of RED, GREEN, BLUE, ALPHA, RGB, RGBA, BGR, BGRA, LUMINANCE,
    or LUMINANCE_ALPHA but the internal format of the texture level
    image is not a color format.

    INVALID_OPERATION is generated if GetTexImage parameter <format>
    is DEPTH_COMPONENT but the internal format of the texture level
    image is not a depth format.

    Eliminate the INVALID_ENUM generated if GetTexImage parameter
    <format> is DEPTH_COMPONENT.  (but this should still be an error for
    GetColorTable, GetConvolutionFilter, GetHistogram, and GetMinmax).
```

New State

In table 6.12, Texture Objects, p. 202, add the following:

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
TEXTURE_DEPTH_SIZE	Z+	GetTexLevelParameter	0	xD texture image i's depth resolution	3.8	-

In table 6.16, Texture Objects, p. 224, add the following:

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
DEPTH_TEXTURE_MODE_ARB	Z_3	GetTexParameter[if]v	LUMINANCE	depth texture mode	3.8.13	texture

New Implementation Dependent State

None

Revision History

```
    19 March 2001
        - initial version
    22 June 2001
        - added 1D textures to issue 4
    16 November 2001
        - removed TEXTURE_BORDER_DEPTH.  use the first component of
          TEXTURE_BORDER_COLOR to specify the depth border value.
        - Added new language in section 3.8.5 to describe how
          TEXTURE_BORDER_COLOR is used with depth textures.
        - Inserted new issue item #4.
    17 November 2001
        - Changed issue 4 resolution.
        - Rewrote section 3.8.4
    12 December 2001 (Pat Brown)
        - Retargeted against the OpenGL 1.3 specification.
        - Depth textures are allowed only on 1D and 2D targets.  Shadowing is
          problematic for 3D and cube map textures.
        - Updated base and sized internal format tables.
        - Documented a couple missing error conditions for TexImage and
          TexSubImage calls where <format> and the texture internal format are
          incompatible.
        - Minor cleanups to provide for depth components in wording that
          formerly assumed RGBA components only.
    13 December 2001
        - Removed a few lingering references to glTexImage3D.
        - Rewrite the first and last error conditions to be clearer.
        - replace "1.2" with "1.3" in a few places.
    - fixed a few more error conditions (Pat Brown)
    11 January 2002
        - fixed "intented" typo
        - added sentence saying that TEXTURE_LUMINANCE_SIZE may be used
          to query the effective resolution of a depth textures when it's
          interpreted as a luminance texture.
    18 January 2002
        - Allow depth textures to be used as LUMINANCE, INTENSITY or ALPHA
          textures (Bimal Poddar)
```

```
21 January 2002
    - Added issue #8 to deal with actual depth texture precision.
      Fixed error to be INVALID_ENUM instead of INVALID_OPERATION.
13 May 2004 (mjk)
    - Document GetTexImage behavior when depth texture formats are
      supported.
    - Document that GetColorTable, GetConvolutionFilter, GetHistogram,
      and GetMinmax now differ from GetTexImage in that
      DEPTH_COMPONENT is (still) not a legal format for these
      queries.
    - Document in "New Tokens" that DEPTH_COMPONENT is a newly accepted
      token for the <internalFormat> parameter of TexImage1D,
      TexImage2D, CopyTexImage1D and CopyTexImage2D; and the <format>
      parameter of GetTexImage, TexImage1D, TexImage2D, TexSubImage1D,
      and TexSubImage2D.
    - Fix mangled sentence in 3.8.5
```

    Last Modified Date: July 26, 2004
    Revision: 14

Number

    ARB Extension #37

Dependencies

    The extension is written against the OpenGL 1.5 Specification.

    OpenGL 1.3 is required.

    ARB_fragment_program affects the definition of this extension.

    ARB_fragment_shader affects the definition of this extension.

Overview

    This extension extends ARB_fragment_program and ARB_fragment_shader
    to allow multiple output colors, and provides a mechanism for
    directing those outputs to multiple color buffers.

Issues

(1) How many GL_DRAW_BUFFER#_ARB enums should be reserved?

      RESOLVED: We only need 4 currently, but for future expandability
      it would be nice to keep the enums in sequence. We'll specify
      16 for now, which will be more than enough for a long time.

```
    (2) How should multisample work when there are multiple output
        colors being rendered to multiple draw buffers?

      Basic options are:
        (a) Color 0 is written to the multisample buffer and then the
            multisample buffer is resolved to all the color buffers.
            This option would be consistent with GL's idea of a single
            multisample buffer, but would be really useless and defeat
            the purpose of multiple output colors.
        (b) Have a separate multisample color buffer for each output
            color/draw buffer.  This would be useful but would all
            implementations be able to handle it?
        (c) Don't allow multiple output colors and multisampling to
            be combined by restricting MAX_DRAW_BUFFERS_ARB to 1
            for contexts with multisample buffers.  This is simple
            and would allow a future extension to allow (b).

      RESOLUTION: (b) and (c).  Samples will contain separate color
      values for each output color.  Implementations that can not
      support this can restrict MAX_DRAW_BUFFERS_ARB to 1 for contexts
      with multisample buffers.

    (3) Should gl_FragColor be aliased to gl_FragData[0]?

      RESOLUTION: No.  A shader should write either gl_FragColor, or
      gl_FragData[n], but not both.

      Writing to gl_FragColor will write to all draw buffers specified
      with DrawBuffersARB.

    (4) Should gl_FragData[n] be clamped?

      RESOLUTION: They will be clamped if fragment color clamping is
      enabled.
```

New Procedures and Functions

```
    void DrawBuffersARB(sizei n, const enum *bufs);
```

New Tokens

```
    Accepted by the <pname> parameters of GetIntegerv, GetFloatv,
    and GetDoublev:

        MAX_DRAW_BUFFERS_ARB                        0x8824
        DRAW_BUFFER0_ARB                            0x8825
        DRAW_BUFFER1_ARB                            0x8826
        DRAW_BUFFER2_ARB                            0x8827
        DRAW_BUFFER3_ARB                            0x8828
        DRAW_BUFFER4_ARB                            0x8829
        DRAW_BUFFER5_ARB                            0x882A
        DRAW_BUFFER6_ARB                            0x882B
        DRAW_BUFFER7_ARB                            0x882C
        DRAW_BUFFER8_ARB                            0x882D
        DRAW_BUFFER9_ARB                            0x882E
        DRAW_BUFFER10_ARB                           0x882F
```

DRAW_BUFFER11_ARB	0x8830
DRAW_BUFFER12_ARB	0x8831
DRAW_BUFFER13_ARB	0x8832
DRAW_BUFFER14_ARB	0x8833
DRAW_BUFFER15_ARB	0x8834

Additions to Chapter 2 of the OpenGL 1.5 Specification (OpenGL Operation)

None

Additions to Chapter 3 of the OpenGL 1.5 Specification (Rasterization)

Modify Section 3.2.1, Multisampling (p. 71)

(replace the second paragraph with)

An additional buffer, called the multisample buffer, is added to the framebuffer. Pixel sample values, including color, depth, and stencil values, are stored in this buffer. Samples contain separate color values for each output color. When the framebuffer includes a multisample buffer, it does not include depth or stencil buffers, even if the multisample buffer does not store depth or stencil values. Color buffers (left, right, front, back, and aux) do coexist with the multisample buffer, however.

Modify Section 3.11.2, Fragment Program Grammar and Semantic Restrictions (ARB_fragment_program)

(replace <resultBinding> grammar rule with these rules)

```
<resultBinding>        ::= "result" "." "color" <optOutputColorNum>
                         | "result" "." "depth"

<optOutputColorNum>    ::= ""
                         | "[" <outputColorNum> "]"

<outputColorNum>       ::= <integer> from 0 to MAX_DRAW_BUFFERS_ARB-1
```

Modify Section 3.11.3.4, Fragment Program Results

(modify Table X.3)

Binding	Components	Description
result.color[n]	(r,g,b,a)	color n
result.depth	(*,*,*,d)	depth coordinate

Table X.3: Fragment Result Variable Bindings. Components labeled "*" are unused. "[n]" is optional -- color <n> is used if specified; color 0 is used otherwise.

(modify third paragraph) If a result variable binding matches "result.color[n]", updates to the "x", "y", "z", and "w" components of the result variable modify the "r", "g", "b", and "a" components, respectively, of the fragment's corresponding output color. If "result.color[n]" is not both bound by the fragment program and written by some instruction of the program, the output color <n> of the fragment program is undefined.

Add a new Section 3.11.4.5.3 (ARB_fragment_program)

3.11.4.5.3 Draw Buffers Program Option

If a fragment program specifies the "ARB_draw_buffers" option, it will generate multiple output colors, and the result binding "result.color[n]" is allowed, as described in section 3.11.3.4, and with modified grammar rules as set forth in section 3.11.2. If this option is not specified, a fragment program that attempts to bind "result.color[n]" will fail to load, and only "result.color" will be allowed.

Add a new section 3.11.6 (ARB_fragment_shader)

Section 3.11.6 Fragment Shader Output

The OpenGL Shading Language specification describes the values that may be output by a fragment shader. These are gl_FragColor, gl_FragData[n], and gl_FragDepth. If fragment color clamping is enabled, the final fragment color values or the final fragment data values written by a fragment shader are clamped to the range [0,1] and then converted to fixed-point as described in section 2.13.9, Final Color Processing.

The final fragment depth written by a fragment shader is first clamped to [0,1] then converted to fixed-point as if it were a window z value. See Section 2.10.1, Controlling the Viewport. Note that the depth range computation is NOT applied here, only the conversion to fixed-point.

The OpenGL Shading Language specification defines what happens when color and/or depth are not written. Those rules are repeated here.

Writing to gl_FragColor specifies the fragment color that will be used by the subsequent fixed functionality pipeline. If subsequent fixed functionality consumes fragment color and an execution of a fragment shader does not write a value to gl_FragColor then the fragment color consumed is undefined.

Writing to gl_FragData[n] specifies the fragment data that will be used by the subsequent fixed functionality pipeline. If subsequent fixed functionality consumes fragment data and an execution of a fragment shader does not write a value to gl_FragData[n] then the fragment data consumed is undefined.

If a shader statically assigns a value to gl_FragColor, it may not assign a value to gl_FragData[n]. If a shader statically writes a value to gl_FragData[n], it may not assign a value to gl_FragColor. That is, a shader may assign values to either gl_FragColor or gl_FragData[n], but not both.

Writing to gl_FragDepth will establish the depth value for the fragment being processed. If depth buffering is enabled, and a shader does not write gl_FragDepth, then the fixed function value for depth will be used as the fragment's depth value. If a shader statically assigns a value to gl_FragDepth, and there is an execution path through the shader that does not set gl_FragDepth, then the value of the fragment's depth may be undefined for some executions of the shader. That is, if a shader statically writes gl_FragDepth, then it is responsible for always writing it.

Note, statically assigning a value to gl_FragColor, gl_FragData[n] or gl_FragDepth means that there is a line of code in the fragment shader source that writes a value to gl_FragColor, gl_FragData[n] or gl_FragDepth, respectively, even if that line of code is never executed.

Additions to Chapter 4 of the OpenGL 1.5 Specification (Per-Fragment Operations and the Frame Buffer)

Replace Section 4.2.1, Selecting a Buffer for Writing (p. 183)

4.2.1 Selecting Color Buffers for Writing

The first such operation is controlling the color buffers into which each of the output colors are written. This is accomplished with either DrawBuffer or DrawBuffersARB.

The command

```
  void DrawBuffer(enum buf);
```

defines the set of color buffers to which output color 0 is written. <buf> is a symbolic constant specifying zero, one, two, or four buffers for writing. The constants are NONE, FRONT_LEFT, FRONT_RIGHT, BACK_LEFT, BACK_RIGHT, FRONT, BACK, LEFT, RIGHT, FRONT_AND_BACK, and AUX0 through AUXn, where n + 1 is the number of available auxiliary buffers.

The constants refer to the four potentially visible buffers front left, front right, back left, and back right, and to the auxiliary buffers. Arguments other than AUXi that omit reference to LEFT or RIGHT refer to both left and right buffers. Arguments other than AUXi that omit reference to FRONT or BACK refer to both front and back buffers. AUXi enables drawing only to auxiliary buffer i. Each AUXi adheres to AUXi = AUX0 + i. The constants and the buffers they indicate are summarized in Table 4.3. If DrawBuffer is supplied with a constant (other than NONE) that does not indicate any of the color buffers allocated to the GL context, the error INVALID_OPERATION results.

symbolic constant	front left	front right	back left	back right	aux i
NONE					
FRONT_LEFT	*				
FRONT_RIGHT		*			
BACK_LEFT			*		
BACK_RIGHT				*	
FRONT	*	*			

BACK			*	*	
LEFT	*		*		
RIGHT		*		*	
FRONT_AND_BACK	*	*	*	*	
AUXi					*

Table 4.3: Arguments to DrawBuffer and the buffers that they indicate.

DrawBuffer will set the draw buffer for output colors other than 0 to NONE.

The command

```
void DrawBuffersARB(sizei n, const enum *bufs);
```

defines the draw buffers to which all output colors are written. <n> specifies the number of buffers in <bufs>. <bufs> is a pointer to an array of symbolic constants specifying the buffer to which each output color is written. The constants may be NONE, FRONT_LEFT, FRONT_RIGHT, BACK_LEFT, BACK_RIGHT, and AUX0 through AUXn, where n + 1 is the number of available auxiliary buffers. The draw buffers being defined correspond in order to the respective output colors. The draw buffer for output colors beyond <n> is set to NONE.

Except for NONE, a buffer should not appear more then once in the array pointed to by <bufs>. Specifying a buffer more then once will result in the error INVALID_OPERATION.

If a fragment program is not using the "ARB_draw_buffers" option, DrawBuffersARB specifies a set of draw buffers into which output color 0 is written.

If a fragment shader writes to "gl_FragColor", DrawBuffersARB specifies a set of draw buffers into which the color written to "gl_FragColor" is written.

The maximum number of draw buffers is implementation dependent and must be at least 1. The number of draw buffers supported can be queried with the state MAX_DRAW_BUFFERS_ARB.

The constants FRONT, BACK, LEFT, RIGHT, and FRONT_AND_BACK that refer to multiple buffers are not valid for use in DrawBuffersARB and will result in the error INVALID_OPERATION.

If DrawBuffersARB is supplied with a constant (other than NONE) that does not indicate any of the color buffers allocated to the GL context, the error INVALID_OPERATION will be generated. If <n> is greater than MAX_DRAW_BUFFERS_ARB, the error INVALID_OPERATION will be generated.

Indicating a buffer or buffers using DrawBuffer or DrawBuffersARB causes subsequent pixel color value writes to affect the indicated buffers. If more than one color buffer is selected for drawing, blending and logical operations are computed and applied independently for each buffer. If there are multiple output colors being written to multiple buffers, the alpha used in alpha to coverage and alpha test is the alpha of output color 0.

Specifying NONE as the draw buffer for an output color will inhibit that output color from being written to any buffer.

Monoscopic contexts include only left buffers, while stereoscopic contexts include both left and right buffers. Likewise, single buffered contexts include only front buffers, while double buffered contexts include both front and back buffers. The type of context is selected at GL initialization.

The state required to handle color buffer selection is an integer for each supported output color. In the initial state, draw buffer for output color 0 is FRONT if there are no back buffers; otherwise it is BACK. The initial state of draw buffers for output colors other then 0 is NONE.

Additions to Chapter 5 of the OpenGL 1.5 Specification (Special Functions)

None

Additions to Chapter 6 of the OpenGL 1.5 Specification (State and State Requests)

None

Additions to Chapter 3 of the OpenGL Shading Language 1.10 Specification (Basics)

Add a new Section 3.3.1, GL_ARB_draw_buffers Extension (p. 13)

3.3.1 GL_ARB_draw_buffers Extension

To use the GL_ARB_draw_buffers extension in a shader it must be enabled using the #extension directive.

The shading language preprocessor #define GL_ARB_draw_buffers will be defined to 1, if the GL_ARB_draw_buffers extension is supported.

Dependencies on ARB_fragment_program

If ARB_fragment_program is not supported then all changes to section 3.11 of ARB_fragment_program and the fragment program specific part of section 4.2.1 are removed.

Dependencies on ARB_fragment_shader

If ARB_fragment_shader is not supported then all changes to section 3.11 of ARB_fragment_shader, section 3.3.1 of the Shading Language Specification, and the fragment shader specific part of section 4.2.1 are removed.

Interactions with possible future extensions

If there is some other future extension that defines multiple

    color outputs then this extension and glDrawBuffersARB could be
    used to define the destinations for those outputs. This extension
    need not be used only with ARB_fragment_program.

Errors

    The error INVALID_OPERATION is generated by DrawBuffersARB if a
    color buffer not currently allocated to the GL context is specified.

    The error INVALID_OPERATION is generated by DrawBuffersARB if <n>
    is greater than the state MAX_DRAW_BUFFERS_ARB.

    The error INVALID_OPERATION is generated by DrawBuffersARB if value
    in <bufs> does not correspond to one of the allowed buffers.

    The error INVALID_OPERATION is generated by DrawBuffersARB if a draw
    buffer other then NONE is specified more then once in <bufs>.

New State

    (table 6.19, p227) add the following entry:

Get Value	Type	Get Command	Initial Value	Description	Section	Attribute
DRAW_BUFFERi_ARB	Z10*	GetIntegerv	see 4.2.1	Draw buffer selected for output color i	4.2.1	color-buffer

New Implementation Dependent State

Get Value	Type	Get Command	Minimum Value	Description	Sec.	Attribute
MAX_DRAW_BUFFERS_ARB	Z+	GetIntegerv	1	Maximum number of active draw buffers	4.2.1	-

Revision History

```
   Date: 7/26/2004
   Revision: 14
      - Clarified interaction of gl_FragColor and multiple draw buffers.
      - Updated dependencies section.
      - Added real ARB extension #.

   Date: 7/22/2004
   Revision: 13
      - Converted from ATI_draw_buffers to ARB_draw_buffers.

   Date: 7/21/2004
   Revision: 12
      - Updated intro to mention ARB_fragment_shader.
      - Marked which sections modify ARB_fragment_program and
        ARB_fragment_shader.
      - Added "Dependencies on ARB_fragment_shader".
      - Added extension section 3.3.1 to Shading Language spec.
      - Resolved interaction with multisample (issue 2).
      - Fixed typos.

   Date: 6/9/2004
```

```
    Revision: 11
       - Added GLSL integration.

    Date: 4/27/2004
    Revision: 10
       - Replaced modification to section 4.2.1 with a complete
         replacement for the section, the individual modifications were
         getting too cumbersome.
       - Added issue (2) on multisampling.

    Date: 4/15/2004
    Revision: 9
       - Specified that it is the alpha of color 0 that is used for alpha
         test.

    Date: 12/30/2002
    Revision: 8
       - Clarified that DrawBuffersATI will set the set of draw buffers
         to write color output 0 to when the "ATI_draw_buffer" fragments
         program option is not in use.

    Date: 9/27/2002
    Revision: 7
       - Fixed confusion between meaning of color buffer and draw buffer
         in last revision.
       - Fixed mistake in when an error is generated based on the <n>
         argument of DrawBuffersATI.

    Date: 9/26/2002
    Revision: 6
       - Cleaned up and put in sync with latest ARB_fragment_program
         revision (#22).  Some meaningless changes made just in the name
         of consistency.

    Date: 9/11/2002
    Revision: 5
       - Added section 3.11.4.5.3.
       - Added enum numbers to New Tokens.

    Date: 9/9/2002
    Revision: 4
       - Changed error from MAX_OUTPUT_COLORS to MAX_DRAW_BUFFERS_ATI.
       - Changed 3.10 section numbers to 3.11 to match change to
         ARB_fragment_program spec.
       - Changed ARB_fragment_program from required to affects, and
         added section on interactions with it and future extensions
         that define multiple color outputs.

    Date: 9/6/2002
    Revision: 3
       - Changed error to INVALID OPERATION.
       - Cleaned up typos.

    Date: 8/19/2002
    Revision: 2
       - Added a paragraph that specifically points out that the
         constants that refer to multiple buffers are not allowed with
```

```
          DrawBuffersATI.
        - Changed bufs to <bufs> in a couple of places.

    Date: 8/16/2002
    Revision: 1
        - First draft for circulation.
```

    Last Modified Date: August 22, 2003
    Revision: 26

Number

    ARB Extension #27

Dependencies

    The extension is written against the OpenGL 1.3 Specification.

    OpenGL 1.3 is required.

    EXT_texture_lod_bias or OpenGL 1.4 is required.

    OpenGL 1.4 affects the definition of this extension.

    ARB_vertex_blend and EXT_vertex_weighting affect the definition of
    this extension.

    ARB_matrix_palette affects the definition of this extension.

    ARB_transpose_matrix affects the definition of this extension.

    EXT_fog_coord affects the definition of this extension.

    EXT_texture_rectangle affects the definition of this extension.

    ARB_shadow interacts with this extension.

    ARB_vertex_program interacts with this extension.

    ATI_fragment_shader interacts with this extension.

    NV_fragment_program interacts with this extension.

Overview

Unextended OpenGL mandates a certain set of configurable per-fragment computations defining texture application, texture environment, color sum, and fog operations. Several extensions have added further per-fragment computations to OpenGL. For example, extensions have defined new texture environment capabilities (ARB_texture_env_add, ARB_texture_env_combine, ARB_texture_env_dot3, ARB_texture_env_crossbar), per-fragment depth comparisons (ARB_depth_texture, ARB_shadow, ARB_shadow_ambient, EXT_shadow_funcs), per-fragment lighting (EXT_fragment_lighting, EXT_light_texture), and environment mapped bump mapping (ATI_envmap_bumpmap).

Each such extension adds a small set of relatively inflexible per-fragment computations.

This inflexibility is in contrast to the typical flexibility provided by the underlying programmable floating point engines (whether micro-coded fragment engines, DSPs, or CPUs) that are traditionally used to implement OpenGL's texturing computations. The purpose of this extension is to expose to the OpenGL application writer a significant degree of per-fragment programmability for computing fragment parameters.

For the purposes of discussing this extension, a fragment program is a sequence of floating-point 4-component vector operations that determines how a set of program parameters (not specific to an individual fragment) and an input set of per-fragment parameters are transformed to a set of per-fragment result parameters.

The per-fragment computations for standard OpenGL given a particular set of texture and fog application modes (along with any state for extensions defining per-fragment computations) is, in essence, a fragment program. However, the sequence of operations is defined implicitly by the current OpenGL state settings rather than defined explicitly as a sequence of instructions.

This extension provides an explicit mechanism for defining fragment program instruction sequences for application-defined fragment programs. In order to define such fragment programs, this extension defines a fragment programming model including a floating-point 4-component vector instruction set and a relatively large set of floating-point 4-component registers.

The extension's fragment programming model is designed for efficient hardware implementation and to support a wide variety of fragment programs. By design, the entire set of existing fragment programs defined by existing OpenGL per-fragment computation extensions can be implemented using the extension's fragment programming model.

Issues

This extension is closely related to ARB_vertex_program, and is in sync with revision 36 of that spec. ARB_fragment_program will continue to track changes made to ARB_vertex_program.

(1) Should we provide precision queries?

RESOLVED: We've decided not to include precision queries. Implementations are expected to meet or exceed the precision guidelines set forth in the core GL spec, section 2.1.1, p. 6, as ammended by this extension.

To summarize section 2.1.1, the maximum representable magnitude of colors must be at least 2^10, while the maximum representable magnitude of other floating-point values must be at least 2^32. The individual results of floating-point operations must be accurate to about 1 part in 10^5.

Here are the reasons why precision queries were not included:

1. It is unclear what the queries should be:
   a) min, max, [0,1) granularity
   b) min +, max +, min -, max -, [0,1) granularity
   c) IEEE mantissa bits, IEEE exponent bits
2. Due to instruction emulation, there is no way to query the actual precision that can be expected. Should the query return the best-case or worst-case precision?
3. Implementations may support multiple precisions, on a per-instruction basis or across the board. How would this be exposed?
4. Current implementations are able to meet the minimum requirements specified in the core GL, thanks to its sufficiently loose wording "... so that the individual results of floating-point operations are accurate to ABOUT 1 part in 10^5." (Emphasis added.)
5. A conformance test can act as watchdog to ensure implementations are not cutting corners on precision.
6. Adding precision queries would require a new entrypoint.

See issue 22 regarding reduced-precision modes.

(2) Should the LOD biased texture sample be optional?

RESOLVED: TXB support is mandatory. This exposes useful functionality which enables blurring and sharpening effects. It will be more useful to entirely override derivatives (scale factor) rather than just biasing the level-of-detail. This would be a future extension to fragment programs.

It should be noted here that the bias introduced per-fragment by TXB is added to any per-object or per-stage LOD bias. If per-fragment LOD bias is not necessary, using the per-object and/or per-stage LOD biases may perform better.

(3) Should we include the ability to bind to the color matrix? How about others? Program matrices?

RESOLVED: We will not specifically add anything that depends on the ARB_imaging subset. So we have not included matrix bindings to the color matrix (or parameter bindings to the color biases, etc.). However, we have included matrix binding support and support for all of the matrices present in ARB_vertex_program.

(4) Should we include the ability to bind to just a texcoord attribute's S,T components? (Or just S, or S,T,P for that matter?)

RESOLVED: No. Issue #15 below obviates this issue by making the texture coordinate usage within a program explicit, thereby making optimizations to reduce the number of interpolated texture coordinates something an implementation can do at compile time instead of having to do it during every texture target change.

(5) What other instructions should be added? Should any be removed?

RESOLVED: The differences between the ARB_vertex_program instruction set and the ARB_fragment_program instruction set are minimal. ARB_fragment_program removes the LOG and EXP rough approximation instructions and the ARL address register load instruction. ARB_fragment_program adds the SIN/COS/SCS trigonometric instructions, the LRP linear interpolation instruction, the CMP compare instruction, and the TEX/TXP/TXB/KIL texture instructions.

(6) Should depth output be a program option or a mandatory feature?

RESOLVED: Depth output capability should be mandatory.

(6a) How should per-vertex geometric depth clipping be handled when replacing depth in a fragment program?

RESOLVED: Per-vertex geometric depth clipping should be performed by the GL as usual, so no spec change is required. The ideal behavior would be to disable near and far clipping planes when replacing depth, but not all implementations can natively support disabling individual clip planes.

(6b) How should depth output from the fragment program be further processed before being handed to the per-fragment operations?

RESOLVED: Depth gets clamped by GL to [0,1]. App has access to depth range as a bindable parameter if it wants to either scale and bias its depth to fall within the depth range, or to kill fragments outside the depth range.

(7) If a fragment program does not write a color value, what should be the final color of the fragment?

RESOLVED: The final fragment color is undefined. Note that it may be perfectly reasonable to have a program that computes depth values but not colors. Fragment colors are often irrelevant if color writes are disabled (via ColorMask).

(7a) If a fragment program does not write a depth value, what should be the final depth value of the fragment?

RESOLVED: "Depth fly-over" (using the conventional depth produced by rasterization) should happen whenever a depth-replacing program is not in use. A depth-replacing program is defined as a program that writes to result.depth in at least one instruction. The presence of a depth declaration alone DOES NOT designate a depth-replacing program. The intention is that a future extension introducing conditional execution will still consider a program to be depth-replacing even if the instruction(s) writing to result.depth do(es) not execute.

Other considered definitions of depth-replacing program:

1. The presence of a depth declaration -OR- the use of result.depth as an instruction destination anywhere in the program designates a depth-replacing program.
2. Every program is a depth-replacing program, but the GL initializes the depth output to be the depth produced by rasterization. The app may then overwrite the depth output.
3. Every program is a depth-replacing program, and the app is solely responsible for copying the depth input to depth output if desired.

(8) Should relative addressing, like that defined in ARB_vertex_program, be supported in this spec?

RESOLVED: No, relative addressing won't be included in this spec.

(9) Should full-featured operand component swizzling, like that defined in ARB_vertex_program, be supported in this spec?

RESOLVED: Yes, full swizzling is mandatory.

(10) Should texture instructions contain specific limitations on operations that can be performed? For example, should write masks or operand component swizzling be disallowed?

RESOLVED: Texture instructions are specified to be very similar to ALU instructions. They have been given 3-letter names, they allow writemasking and saturation (which would be useful for floating-point texture formats), source swizzles and negates, and the ability to use parameters as sources.

(11) Should we standardize options for stencil or aux data buffer outputs?

RESOLVED: Stencil and aux data buffers will be saved for a possible future extension to fragment programs.

(12) Should depth output be pulled from the 3rd or 4th component?

RESOLVED: 3rd component, as the 3rd component is also used for depth input from the "fragment.position" attribute.

(13) Which stages are subsumed by fragment programs?

RESOLVED: Texturing, color sum, and fog.

(14) What should the minimum resource limits be?

RESOLVED: 10 attributes, 24 parameters, 4 texture indirections, 48 ALU instructions, 24 texture instructions, and 16 temporaries.

(15) OpenGL provides a hierarchy of texture enables (cube map, 3D, 2D, 1D). Should the texture sampling instructions here override that hierarchy and select specific texture targets?

RESOLVED: Yes. This removes a potential pitfall for developers: leaving the hierarchy of enables in an undesired state. It makes programs more readable as the intent of the sample is more obvious. Finally, it allows compilers to be more aggressive as to which texcoord components are "don't cares" without having to recompile programs when fixed-function texenables change. One drawback is that programs cannot be reused for both 2D and 3D texturing, for example, by simply changing the texture enables.

Texture sampling can be specified by instructions like

```
TEX myTexel, fragment.texcoord[1], texture[2], 3D;
```

which would indicate to use texture coordinate set number 1 to sample from the texture object bound to the TEXTURE_3D target on texture image unit 2.

Each texture unit can have only one "active" target. Programs are not allowed to reference different texture targets in the same texture image unit. In the example above, any other texture instructions using texture image unit 2 must specify the 3D texture target.

Note that every texture image unit always has a texture bound to every texture target, whether it is a named texture object or a default texture. However, the texture may not be complete as defined in section 3.8.9 of the core GL spec. See issue 23.

(16) Should aux texture units be additional units on top of existing full-featured texture units, or should this spec fully deprecate "legacy" texture units and only expose texture coordinate sets and texture image units?

Background: Some implementations are able to expose more "texture image units" (texture maps and associated parameters) than "texture coordinate sets" (current texcoords, texgen, and texture matrices). A conventional GL "texture unit" encompasses both a texture image unit and a texture coordinate set as well as texture environment state.

RESOLVED: Yes, deprecate "legacy" texture units. This is a more flexible model.

(17) Should fragment programs affect all fragments, or just those produced by the rasterization of points, lines, and triangles?

RESOLVED: Every fragment generated by the GL is subject to fragment program mode. This includes point, line, and polygon primitives as well as pixel rectangles and bitmaps.

(18) Should per-fragment position and fogcoord be bindable as fragment attributes?

RESOLVED: Yes, interpolated fogcoord will make per-fragment fog application possible, in addition to full fog stage subsummation. Interpolated window position, especially depth, enables interesting depth-replacing algorithms.

(19) What characters should be used to identify individual components in swizzle selectors and write masks?

RESOLVED: ARB_vertex_program provides "xyzw". This extension supports "xyzw" and also provides "rgba" for better readability when dealing with RGBA color values. Adding support for special identifiers for dealing with texture coordinates was considered and rejected. "strq" could be used to identify texture coordinate components, but the "r" would conflict with the "r" from "rgba". "stpq" would be another possibility, but could be a source of confusion.

(20) Should implementations be required to support all programs that fit within the exported limits on the number of resources (e.g., instructions, temporaries) that can be present in a program, even if it means falling back to software? Should implementations be required to reject programs that could never be accelerated?

RESOLVED: No and no. An implementation is allowed to fail ProgramStringARB due to the program exceeding native resources. Note that this failure must be invariant with respect to all other OpenGL state. In other words, a program cannot succeed to load with default state, but then fail to load when certain GL state is altered. However, an implementation is not required to fail when a program would exceed native resources, and is in fact encouraged to fallback to a software path. See issue 21 for a way of determining if this has happened.

This notable departure from ARB_vertex_program was made as an accommodation to vendors who could not justify implementing a software fallback path which would be relatively slow even compared to an ARB_vertex_program software fallback path.

Two issues with this decision:

1. The API limits become hints, and one can no longer tell by visual inspection whether or not a program will load on every implementation.
2. Program loading will now depend on the optimizer, which may vary from release to release of an implementation. A program that succeeded to load when an ISV first wrote it may fail to load in a future driver version, and vice versa.

(21) How can applications determine if their programs are too large to run on the native (likely hardware) implementation, and therefore may run with reduced performance?

RESOLVED: The following code snippet uses a native resource query to guarantee a program is loaded natively (or not at all):

```
GLboolean ProgramStringIsNative(GLenum target, GLenum format,
                                GLsizei len, const GLvoid *string)
{
    GLint errorPos, isNative;
    glProgramStringARB(target, format, len, string);
    glGetIntegerv(GL_PROGRAM_ERROR_POSITION_ARB, &errorPos);
    glGetProgramivARB(GL_FRAGMENT_PROGRAM_ARB,
        GL_PROGRAM_UNDER_NATIVE_LIMITS_ARB, &isNative);
    if ((errorPos == -1) && (isNative == 1))
        return GL_TRUE;
    else
        return GL_FALSE;
}
```

Note that a program that successfully loads, and falls under the native limits, is still not guaranteed to execute in hardware. Lack of other resources (e.g., texture memory) or the use of other OpenGL features not natively supported by the implementation (e.g., textures with borders) may also prevent the program from executing in hardware.

(22) Should we provide applications with a method to control the level of precision used to carry out fragment program computations?

RESOLVED: Yes. The GL implementation ultimately has control over the level of precision used for fragment program computations. However, the "ARB_precision_hint_fastest" and "ARB_precision_hint_nicest" program options allow applications to guide the GL implementation in its precision selection. The "fastest" option encourages the GL to minimize execution time, with possibly reduced precision. The "nicest" option encourages the GL to maximize precision, with possibly increased execution time.

If the precision hint is not "fastest", GL implementations should perform low-precision operations only if they could not appreciably affect the final results of the program. Regardless of the precision hint, GL implementations are discouraged from reducing the precision of computations so aggressively that final rendering results could be seriously compromised due to overflow of intermediate values or insufficient number of mantissa bits.

Some implementations may provide only a single level of precision, in which case these hints may have no effect. However, all implementations will accept these options, even if they are silently ignored.

More explicit control of precision, such as provided in "C" with data types such as "short", "int", "float", "double", may also be a desirable feature, but this level of detail is left to a separate extension.

(23) What is the result of a sample from an incomplete texture? The definition of texture completeness can be found in section 3.8.9 of the core GL spec.

RESOLVED: The result of a sample from an incomplete texture is the constant vector (0,0,0,1). The benefit of defining the result to be a constant is that broken apps are guaranteed to generate unexpected (black) results from their bad samples. If we were to leave the result undefined, some implementations may generate expected results some of the time, for example when magfiltering, giving app developers a false sense of correctness in their apps.

(24) What is a texture indirection, and how is it counted?

RESOLVED: On some implementations, fragment programs that have complex texture dependency chains may not be supported, even if the instruction counts fit within the exported limits. A texture dependency occurs when a texture instruction depends on the result of a previous instruction (ALU or texture) for use as its texture coordinate.

A texture indirection can be considered a node in the texture dependency chain. Each node contains a set of texture instructions which execute in parallel, followed by a sequence of ALU instructions. A dependent texture instruction is one that uses a temporary as an input coordinate rather than an attribute or a parameter. A program with no dependent texture instructions (or no texture instructions at all) will have a single node in its texture dependency chain, and thus a single indirection.

API-level texture indirections are counted by keeping track of which temporaries are read and written within the current node in the texture dependency chain. When a texture instruction is encountered, an indirection may be added and a new node started if either of the following two conditions is true:

1. the source coordinate of the texture instruction is a temporary that has already been written in the current node, either by a previous texture instruction or ALU instruction;

2. the result of the texture instruction is a temporary that has already been read or written in the current node by an ALU instruction.

The texture instruction provoking a new indirection and all subsequent instructions are added to the new node. This process is repeated until the end of the program is encountered. Below is some pseudo-code to describe this:

```
indirections = 1;
tempsOutput = 0;
aluTemps = 0;
while (i = getInst())
{
  if (i.type == TEX)
  {
    if (((i.input.type == TEMP) &&
          (tempsOutput & (1 << i.input.index))) ||
        ((i.op != KILL) && (i.output.type == TEMP) &&
          (aluTemps & (1 << i.output.index))))
    {
      indirections++;
      tempsOutput = 0;
      aluTemps = 0;
    }
  } else {
    if (i.input1.type == TEMP)
      aluTemps |= (1 << i.input1.index);
    if (i.input2 && i.input2.type == TEMP)
      aluTemps |= (1 << i.input2.index);
    if (i.input3 && i.input3.type == TEMP)
      aluTemps |= (1 << i.input3.index);
    if (i.output.type == TEMP)
      aluTemps |= (1 << i.output.index);
  }
  if ((i.op != KILL) && (i.output.type == TEMP))
    tempsOutput |= (1 << i.output.index);
}
```

    For example, the following programs would have 1, 2, and 3
    texture indirections, respectively:

```
      !!ARBfp1.0
      # No texture instructions, but always 1 indirection
      MOV result.color, fragment.color;
      END

      !!ARBfp1.0
      # A simple dependent texture instruction, 2 indirections
      TEMP myColor;
      MUL myColor, fragment.texcoord[0], fragment.texcoord[1];
      TEX result.color, myColor, texture[0], 2D;
      END

      !!ARBfp1.0
      # A more complex example with 3 indirections
      TEMP myColor1, myColor2;
      TEX myColor1, fragment.texcoord[0], texture[0], 2D;
      MUL myColor1, myColor1, myColor1;
      TEX myColor2, fragment.texcoord[1], texture[1], 2D;
      # so far we still only have 1 indirection
      TEX myColor2, myColor1, texture[2], 2D;      # This is #2
      TEX result.color, myColor2, texture[3], 2D;  # And #3
      END
```

Note that writemasks for the temporaries written and swizzles for the temporaries read are not taken into consideration when counting indirections. This makes hand-counting of indirections by a developer an easier task.

Native texture indirections may be counted differently by an implementation to reflect its exact restrictions, to reflect the true dependencies taking into account writemasks and swizzles, and to reflect optimizations such as instruction reordering.

For implementations with no restrictions on the number of indirections, the maximum indirection count will equal the maximum texture instruction count.

(25) How can a program reduce SCS's scalar operand to the fundamental period [-PI,PI]?

RESOLVED: Unlike the individual SIN and COS instructions, SCS requires that its argument be reduced ahead of time to the fundamental period. The reason SCS doesn't perform this operation automatically is that it may make unnecessary redundant work for programs that already have their operand in the correct range. Other programs that do need to reduce their operand simply need to add a block of code before the SCS instruction:

```
     PARAM myParams = { 0.5, -3.14159, 6.28319, 0.15915 };
     MAD myOperand.x, myOperand.x, myParams.w, myParams.x; # a = (a/(2*PI))+0.5
     FRC myOperand.x, myOperand.x;                         # a = frac(a)
     MAD myOperand.x, myOperand.x, myParams.z, myParams.y  # a = (a*2*PI)-PI
     ...
     SCS myResult, myOperand.x;
```

(26) Is depth output from a fragment program guaranteed to be invariant with respect to depth produced via conventional rasterization?

RESOLVED: No. The floating-point representation of depth values output from a fragment program may lead to the output of depth with less precision than the depth output by convention GL rasterization. For example, a floating-point representation with 16 bits of mantissa will certainly produce depth with lesser precision than that of conventional rasterization used in conjunction with a 24-bit depth buffer, where all values are maintained as integers. Be aware of this when mixing conventional GL rendering with fragment program rendering.

(27) How can conventional GL fog application be achieved within a fragment program?

RESOLVED: Program options have been introduced that allow a program to request fog to be applied to the final clamped fragment color before being passed along to the antialiasing application stage. This makes it easy for:

1. developers to request conventional fog behavior
2. implementations with dedicated fog hardware to use it
3. implementations without dedicated fog hardware, so they need not track fog state after compilation, and constantly recompile when fog state changes.

The three mandatory options are ARB_fog_exp, ARB_fog_exp2, and ARB_fog_linear. As these options are mutually exclusive by nature, specifying more than one is not useful. If more than one is specified, the last one encountered in the <optionSequence> will be the one to actually modify the execution environment.

(28) Why have all of the enums, entrypoints, GLX protocol, and spec language shared with ARB_vertex_program been reproduced here?

RESOLVED: The two extensions are independent of one another, in so far as an implementation need not support both of them in order to support one of them. Everything needed to implement or make use of ARB_fragment_program is present in this spec without the need to refer to the ARB_vertex_program spec. When and if these two extensions are incorporated into the core OpenGL, the significant overlap of the two will be collapsed into a single instance of the shared parts.

(29) How might an implementation implement the fog options? To What does the extra resource consumption described in 3.11.4.5.1 correspond?

RESOLVED: The following code snippets reflect possible implementations of the fog options. While an implementation may use other instruction sequences to achieve the same result, or may use external fog hardware if available, all implementations must enforce the API-level resource consumption as described: 2 params, 1 temp, 1 attribute, and 3, 4, or 2 instructions. "finalColor" in the examples below is the color that would otherwise be

```
    "result.color", with components clamped to the range [0,1].
    "result.color.a" is assumed to have already been written, as fog
    blending does not affect the alpha component.

    EXP:
      # Exponential fog
      # f = exp(-d*z)
      #
      PARAM p = {DENSITY/LN(2), NOT USED, NOT USED, NOT USED};
      PARAM fogColor = state.fog.color;
      TEMP fogFactor;
      ATTRIB fogCoord = fragment.fogcoord.x;
      MUL fogFactor.x, p.x, fogCoord.x;
      EX2_SAT fogFactor.x, -fogFactor.x;
      LRP result.color.rgb, fogFactor.x, finalColor, fogColor;

    EXP2:
      #
      # 2nd-order Exponential fog
      # f = exp(-(d*z)^2)
      #
      PARAM p = {DENSITY/SQRT(LN(2)), NOT USED, NOT USED, NOT USED};
      PARAM fogColor = state.fog.color;
      TEMP fogFactor;
      ATTRIB fogCoord = fragment.fogcoord.x;
      MUL fogFactor.x, p.x, fogCoord.x;
      MUL fogFactor.x, fogFactor.x, fogFactor.x;
      EX2_SAT fogFactor.x, -fogFactor.x;
      LRP result.color.rgb, fogFactor.x, finalColor, fogColor;

    LINEAR:
      #
      # Linear fog
      # f = (end-z)/(end-start)
      #
      PARAM p = {-1/(END-START), END/(END-START), NOT USED, NOT USED};
      PARAM fogColor = state.fog.color;
      TEMP fogFactor;
      ATTRIB fogCoord = fragment.fogcoord.x;
      MAD_SAT fogFactor.x, p.x, fogCoord.x, p.y;
      LRP result.color.rgb, fogFactor.x, finalColor, fogColor;
```

(30) Why is the order of operands for the CMP instruction different than the order used by another popular graphics API?

RESOLVED: No other graphics API was used as a basis for the design of ARB_fragment_program except ARB_vertex_program, which did not have a CMP instruction. This independent evolution naturally led to differences in minor details such as order of operands. This discrepancy is noted here to help developers familiar with the other API to avoid this potential pitfall.

(31) Is depth offset applied to the window z value before it enters the fragment program?

RESOLVED: As in the base OpenGL specification, the depth offset generated by polygon offset is added during polygon rasterization.

    The depth value provided to shaders in the fragment.position.z
    attribute already includes polygon offset, if enabled. If the
    depth value is replaced by a fragment program, the polygon offset
    value will NOT be recomputed and added back after fragment program
    execution.

    NOTE: This is probably not desirable for fragment programs that
    modify depth values since the partials used to generate the offset
    may not match the partials of the computed depth value.

New Procedures and Functions

```
    void ProgramStringARB(enum target, enum format, sizei len,
                          const void *string);

    void BindProgramARB(enum target, uint program);

    void DeleteProgramsARB(sizei n, const uint *programs);

    void GenProgramsARB(sizei n, uint *programs);

    void ProgramEnvParameter4dARB(enum target, uint index,
                                  double x, double y, double z, double w);
    void ProgramEnvParameter4dvARB(enum target, uint index,
                                   const double *params);
    void ProgramEnvParameter4fARB(enum target, uint index,
                                  float x, float y, float z, float w);
    void ProgramEnvParameter4fvARB(enum target, uint index,
                                   const float *params);

    void ProgramLocalParameter4dARB(enum target, uint index,
                                    double x, double y, double z, double w);
    void ProgramLocalParameter4dvARB(enum target, uint index,
                                     const double *params);
    void ProgramLocalParameter4fARB(enum target, uint index,
                                    float x, float y, float z, float w);
    void ProgramLocalParameter4fvARB(enum target, uint index,
                                     const float *params);

    void GetProgramEnvParameterdvARB(enum target, uint index,
                                     double *params);
    void GetProgramEnvParameterfvARB(enum target, uint index,
                                     float *params);

    void GetProgramLocalParameterdvARB(enum target, uint index,
                                       double *params);
    void GetProgramLocalParameterfvARB(enum target, uint index,
                                       float *params);

    void GetProgramivARB(enum target, enum pname, int *params);

    void GetProgramStringARB(enum target, enum pname, void *string);

    boolean IsProgramARB(uint program);
```

New Tokens

```
    Accepted by the <cap> parameter of Disable, Enable, and IsEnabled,
    by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv,

Additions to Chapter 2 of the OpenGL 1.3 Specification (OpenGL Operation)

Modify Section 2.1.1, Floating-Point Computation (p. 6)

(modify first paragraph, p. 6) ... The maximum representable magnitude of a floating-point number used to represent position, normal, or texture coordinates must be at least 2^32; the maximum representable magnitude for colors must be at least 2^10. ...

Modify Section 2.7, Vertex Specification (p. 19)

(modify second paragraph, p. 20) Implementations support more than one set of texture coordinates. The commands

```
  void MultiTexCoord{1234}{sifd}(enum texture, T coords);
  void MultiTexCoord{1234}{sifd}v(enum texture, T coords);
```

take the coordinate set to be modified as the <texture> parameter. <texture> is a symbolic constant of the form TEXTUREi, indicating that texture coordinate set i is to be modified. The constants obey TEXTUREi = TEXTURE0 + i (i is in the range 0 to k-1, where k is the implementation-dependent number of texture units defined by MAX_TEXTURE_COORDS_ARB).

Modify Section 2.8, Vertex Arrays (p. 21)

(modify first paragraph, p. 21) ... The client may specify up to 5 plus the value of MAX_TEXTURE_COORDS_ARB arrays: one each to store vertex coordinates...

(modify first paragraph, p. 23) The command

```
  void ClientActiveTexture(enum texture);
```

is used to select the vertex array client state parameters to be modified by the TexCoordPointer command and the array affected by EnableClientState and DisableClientState with parameter TEXTURE_COORD_ARRAY. This command sets the client state variable CLIENT_ACTIVE_TEXTURE. Each texture coordinate set has a client state vector which is selected when this command is invoked. This state vector includes the vertex array state. This call also selects the texture coordinate set state used for queries of client state.

(modify first paragraph, p. 28) If the number of supported texture coordinate sets (the value of MAX_TEXTURE_COORDS_ARB) is k, ...

Modify Section 2.10.2, Matrices (p. 31)

(modify first paragraph, p. 31) The projection matrix and model-view matrix are set and modified with a variety of commands. The affected matrix is determined by the current matrix mode. The current matrix mode is set with

```
  void MatrixMode(enum mode);
```

which takes one of the pre-defined constants TEXTURE, MODELVIEW, COLOR, PROJECTION, or MATRIX<i>_ARB as the argument. In the case of MATRIX<i>_ARB, <i> is an integer between 0 and <n>-1 indicating one of <n> program matrices where <n> is the value of the implementation defined constant MAX_PROGRAM_MATRICES_ARB. Such program matrices are described in section 3.11.7. TEXTURE is described later in section 2.10.2, and COLOR is described in section 3.6.3. If the current matrix mode is MODELVIEW, then matrix operations apply to the model-view matrix; if PROJECTION, then they apply to the projection matrix.

(modify first paragraph, p. 34) For each texture coordinate set, a 4x4 matrix is applied to the corresponding texture coordinates...

(modify first and second paragraphs, p. 35) The command

```
  void ActiveTexture(enum texture);
```

specifies the active texture unit selector, ACTIVE_TEXTURE. Each texture unit contains up to two distinct sub-units: a texture coordinate processing unit (consisting of a texture matrix stack and texture coordinate generation state) and a texture image unit (consisting of all the texture state defined in Section 3.8). In implementations with a different number of supported texture coordinate sets and texture image units, some texture units may consist of only one of the two sub-units.

The active texture unit selector specifies the texture coordinate set accessed by commands involving texture coordinate processing. Such commands include those accessing the current matrix stack (if MATRIX_MODE is TEXTURE), TexGen (section 2.10.4), Enable/Disable (if any texture coordinate generation enum is selected), as well as queries of the current texture coordinates and current raster texture coordinates. If the texture coordinate set number corresponding to the current value of ACTIVE_TEXTURE is greater than or equal to the implementation-dependent constant MAX_TEXTURE_COORDS_ARB, the error INVALID_OPERATION is generated by any such command.

The active texture unit selector also selects the texture image unit accessed by commands involving texture image processing (section 3.8). Such commands include all variants of TexEnv, TexParameter, and TexImage commands, BindTexture, Enable/Disable for any texture target (e.g., TEXTURE_2D), and queries of all such state. If the texture image unit number corresponding to the current value of ACTIVE_TEXTURE is greater than or equal to the implementation-dependent constant MAX_TEXTURE_IMAGE_UNITS_ARB, the error INVALID_OPERATION is generated by any such command.

ActiveTexture generates the error INVALID_ENUM if an invalid <texture> is specified. <texture> is a symbolic constant of the form TEXTUREi, indicating that texture unit i is to be modified. The constants obey TEXTUREi = TEXTURE0 + i (i is in the range 0 to k-1, where k is the larger of the MAX_TEXTURE_COORDS_ARB and MAX_TEXTURE_IMAGE_UNITS_ARB). For compatibility with old OpenGL specifications, the implementation-dependent constant MAX_TEXTURE_UNITS specifies the number of conventional texture units supported by the implementation. Its value must be no larger than the minimum of MAX_TEXTURE_COORDS_ARB and MAX_TEXTURE_IMAGE_UNITS_ARB.

(modify last paragraph, p. 35) The state required to implement transformations consists of a <n>-value integer indicating the current matrix mode (where <n> is 4 + the number of supported texture and program matrices), a stack of at least two 4x4 matrices for each of COLOR, PROJECTION, and TEXTURE with associated stack pointers, <n> stacks (where <n> is at least 8) of at least one 4x4 matrix for each MATRIX<i>_ARB with associated stack pointers, and a stack of at least 32 4x4 matrices with an associated stack pointer for MODELVIEW. Initially, there is only one matrix on each stack, and all matrices are set to the identity. The initial matrix mode is MODELVIEW. The initial value of ACTIVE_TEXTURE is TEXTURE0.

Additions to Chapter 3 of the OpenGL 1.3 Specification (Rasterization)

Modify Chapter 3, Introduction (p. 58)

(modify first paragraph, p. 58) ... Figure 3.1 diagrams the rasterization process. The color value assigned to a fragment is initially determined by the rasterization operations (sections 3.3 through 3.7) and modified by either the execution of the texturing, color sum, and fog operations as defined in sections 3.8, 3.9, and 3.10, or of a fragment program defined in section 3.11. The final depth value is initially determined by the rasterization operations and may be modified or replaced by a fragment program.

(modify Figure 3.1)

```
             _ +---------------+   FRAGMENT_PROGRAM_ARB
             /||    Point      |          enable
            /  | Rasterization |\           |
           /   +---------------+ \          V  o-------------+
   From   /    +---------------+  \                          |

  Bitmap ----> |    Bitmap     |/        +-----------+
               | Rasterization |
               +---------------+
```

Modify Section 3.3, Points (p. 63)

(modify first and second paragraphs, p. 64) All fragments produced in rasterizing a non-antialiased point are assigned the same associated data, which are those of the vertex corresponding to the point. (delete reference to divide by q)

If antialiasing is enabled, then ... The data associated with each fragment are otherwise the data associated with the point being rasterized. (delete reference to divide by q)

Modify Section 3.4.1, Basic Line Segment Rasterization (p. 66)

(modify first paragraph, p. 68) ... (Note that t=0 at p_a and t=1 at p_b). The value of an associated datum f from the fragment center, whether it be R, G, B, or A (in RGBA mode) or a color index (in color index mode) or the s, t, r, or q texture coordinate or the clip w coordinate (the depth value, window z, must be found using equation 3.3, below), is found as

$$f = \frac{(1-t)*(f_a/w_a) + t*(f_b/w_b)}{(1-t)*(1/w_a) + t*(1/w_b)} \qquad (3.2)$$

where f_a and f_b are the data associated with the starting and ending endpoints of the segment, respectively; w_a and w_b are the clip w coordinates of the starting and ending endpoints of the segments, respectively. Note that linear interpolation would use

$$f = (1-t)*f_a + t*f_b. \qquad (3.3)$$

... A GL implementation may choose to approximate equation 3.2 with 3.3, but this will normally lead to inacceptable distortion effects when interpolating texture coordinates or clip w coordinates.

Modify Section 3.5.1, Basic Polygon Rasterization (p. 73)

(modify third and fourth paragraphs, p. 74) Denote a datum at p_a, p_b, or p_c as f_a, f_b, or f_c, respectively. Then the value f of a datum at a fragment produced by rasterizing a triangle is given by

$$f = \frac{a*(f_a/w_a) + b*(f_b/w_b) + c*(f_c/w_c)}{a*(1/w_a) + b*(1/w_b) + c*(1/w_c)} \qquad (3.4)$$

where w_a, w_b, and w_c are the clip w coordinates of p_a, p_b, and p_c, respectively. a, b, and c are the barycentric coordinates of the fragment for which the data are produced. a, b, and c must correspond precisely to the ... at the fragment's center.

Just as with line segment rasterization, equation 3.4 may be approximated by

$$f = a*f_a + b*f_b + c*f_c;$$

this may yield ... for texture coordinates or clip w coordinates.

Modify Section 3.6.4, Rasterization of Pixel Rectangles (p. 91)

(modify third paragraph, p. 103) A fragment arising from a group ... the color and texture coordinates are given by those associated with the current raster position. (delete reference to divide by q) Groups arising from DrawPixels...

Modify Section 3.7, Bitmaps (p. 113)

(modify third paragraph, p. 114) Otherwise, a rectangular array ... The associated data for each fragment are those associated with the current raster position. (delete reference to divide by q) Once the fragments have been produced ...

Modify Section 3.8, Texturing (p. 115)

(add new paragraphs before first paragraph, p. 115) Texture coordinate sets are mapped to RGBA colors for application to primitives in one of two modes. The first mode, described in this and subsequent sections, is GL's conventional multitexture pipeline, describing texture environment and texture application. The second mode, referred to as fragment program mode and described in section 3.11, applies textures, color sum, and fog as specified in an application-supplied fragment program.

The fragment program mode is enabled and disabled using the generic Enable and Disable commands, respectively, with the symbolic constant FRAGMENT_PROGRAM_ARB. The required state is one bit indicating whether the fragment program mode is enabled or disabled. In the initial state, the fragment program mode is disabled. When fragment program mode is enabled, texturing, color sum, and fog application stages are ignored and a general purpose program is executed instead.

(modify first and second paragraph, p. 115) Conventional texturing is employed when fragment program mode is disabled. Texturing maps ... color of an image at the location indicated by a fragment's texture coordinates to modify the fragment's primary RGBA color. Texturing does not affect the secondary color.

An implementation may support texturing using more than one image at a time. In this case the fragment carries multiple sets of texture coordinates which are used to index ...

(add paragraph before 1st paragraph, p. 116) Except when in fragment program mode (section 3.11), the (s,t,r) texture coordinates used for texturing are the values s/q, t/q, and r/q, respectively, where s, t, r, and q are the texture coordinates associated with the fragment. When in fragment program mode, the (s,t,r) texture coordinates are specified by the program. If q is less than or equal to zero, the results of texturing are undefined.

Modify Section 3.8.7, Texture Minification (p. 135)

(add new paragraph after first paragraph, p. 137) When fragment program mode is enabled, the derivatives of the coordinates may be ill-defined or non-existent. As a result, the implementation is free to approximate these derivatives with such techniques as differencing. The only requirement is that texture samples be equivalent across the two modes. In other words, the texture sample chosen for a fragment of a primitive must be invariant between fragment program mode and conventional mode subject to the rules set forth in Appendix A, Invariance.

Modify Section 3.8.13, Texture Application (p. 149)

(modify fourth paragraph, p. 152) Texturing is enabled and disabled individually for each texture unit. If texturing is disabled for one of the units, then the fragment resulting from the previous unit is passed unaltered to the following unit. Individual texture units beyond those specified by MAX_TEXTURE_UNITS may be incomplete and are always treated as disabled.

Insert a new Section 3.11, (p. 154), between existing sections 3.10 and 3.11. Renumber 3.11, Antialiasing Application, to 3.12.

3.11 Fragment Programs

The conventional GL texturing model described in section 3.8 is a configurable but essentially hard-wired sequence of per-fragment computations based on a canonical set of per-fragment parameters and texturing-related state such as texture images, texture parameters, and texture environment parameters. The general success and utility of the conventional GL texturing model reflects its basic correspondence to the typical texturing requirements of 3D applications.

However when the conventional GL texturing model is not sufficient, the fragment program mode provides a substantially more flexible model for generating fragment colors. The fragment program mode permits applications to define their own fragment programs.

A fragment program is a character string that specifies a sequence of operations to perform. Fragment program instructions are typically 4-component vector operations that operate on per-fragment attributes and program parameters. Fragment programs execute on a per-fragment basis and operate on each fragment completely independently from any other fragments. Fragment programs execute a finite fixed sequence of instructions with no branching or looping. Fragment programs execute without data hazards so results computed in one instruction can be used immediately afterwards. The result of a fragment program is a set of fragment result registers that becomes the color used by antialiasing application and/or a depth value used in place of the interpolated depth value generated by conventional rasterization.

In fragment program mode, the color sum is subsumed by the fragment program. An application desiring the primary and secondary colors to be summed must explicitly include this operation in its program.

Fragment programs are defined to operate only in RGBA mode. The results of fragment program execution are undefined if the GL is in color index mode.

3.11.1 Program Objects

The GL provides one or more program targets, each identifying a portion of the GL that can be controlled through application-specified programs. The program target for fragment programs is FRAGMENT_PROGRAM_ARB. Each program target has an associated program object, called the current program object. Each program target also has a default program object, which is initially the current program object.

Each program object has an associated program string. The command

```
  ProgramStringARB(enum target, enum format, sizei len,
                   const void *string);
```

updates the program string for the current program object for <target>. <format> describes the format of the program string, which must currently be PROGRAM_FORMAT_ASCII_ARB. <string> is a pointer to the array of bytes representing the program string being loaded, which need not be null-terminated. The length of the array is given by <len>. If <string> is null-terminated, <len> should not include the terminator.

When a program string is loaded, it is interpreted according to syntactic and semantic rules corresponding to the program target specified by <target>. If a program violates the syntactic or semantic restrictions of the program target, ProgramStringARB generates the error INVALID_OPERATION. An implementation may also generate the error INVALID_OPERATION if the program would exceed the native resource limits defined in section 6.1.12. A program which fails to load due to exceeding native resource limits must always fail, regardless of any other GL state.

Additionally, ProgramString will update the program error position (PROGRAM_ERROR_POSITION_ARB) and error string (PROGRAM_ERROR_STRING_ARB). If a program fails to load, the value of the program error position is set to the ubyte offset into the specified program string indicating where the first program error was detected. If the program fails to load because of a semantic restriction that is not detected until the program is fully scanned, the error position is set to the value of <len>. If a program loads successfully, the error position is set to the value negative one. The implementation-dependent program error string contains one or more error or warning messages. If a program loads succesfully, the error string may either contain warning messages or be empty.

Each program object has an associated array of program local parameters. The number and type of program local parameters is target- and implementation-dependent. For fragment programs, program local parameters are four-component floating-point vectors. The number of vectors is given by the implementation-dependent constant MAX_PROGRAM_LOCAL_PARAMETERS_ARB, which must be at least 24. The commands

```
      void ProgramLocalParameter4fARB(enum target, uint index,
                                      float x, float y, float z, float w);
      void ProgramLocalParameter4fvARB(enum target, uint index,
                                       const float *params);
      void ProgramLocalParameter4dARB(enum target, uint index,
                                      double x, double y, double z, double w);
      void ProgramLocalParameter4dvARB(enum target, uint index,
                                       const double *params);
```

update the values of the program local parameter numbered <index> belonging to the program object currently bound to <target>. For ProgramLocalParameter4fARB and ProgramLocalParameter4dARB, the four components of the parameter are updated with the values of <x>, <y>, <z>, and <w>, respectively. For ProgramLocalParameter4fvARB and ProgramLocalParameter4dvARB, the four components of the parameter are updated with the array of four values pointed to by <params>. The error INVALID_VALUE is generated if <index> is greater than or equal to the number of program local parameters supported by <target>.

Additionally, each program target has an associated array of program environment parameters. Unlike program local parameters, program environment parameters are shared by all program objects of a given target. The number and type of program environment parameters is target- and implementation-dependent. For fragment programs, program environment parameters are four-component floating-point vectors. The number of vectors is given by the implementation-dependent constant MAX_PROGRAM_ENV_PARAMETERS_ARB, which must be at least 24. The commands

```
      void ProgramEnvParameter4fARB(enum target, uint index,
                                    float x, float y, float z, float w);
      void ProgramEnvParameter4fvARB(enum target, uint index,
                                     const float *params);
      void ProgramEnvParameter4dARB(enum target, uint index,
                                    double x, double y, double z, double w);
      void ProgramEnvParameter4dvARB(enum target, uint index,
                                     const double *params);
```

update the values of the program environment parameter numbered <index> for the given program target <target>. For ProgramEnvParameter4fARB and ProgramEnvParameter4dARB, the four components of the parameter are updated with the values of <x>, <y>, <z>, and <w>, respectively. For ProgramEnvParameter4fvARB and ProgramEnvParameter4dvARB, the four components of the parameter are updated with the array of four values pointed to by <params>. The error INVALID_VALUE is generated if <index> is greater than or equal to the number of program environment parameters supported by <target>.

Each program target has a default program object. Additionally, named program objects can be created and operated upon. The name space for program objects is the positive integers and is shared by programs of all targets. The name zero is reserved by the GL.

A named program object is created by binding an unused program object name to a valid program target. The binding is effected by calling

```
  BindProgramARB(enum target, uint program);
```

with <target> set to the desired program target and <program> set to the unused program name. The resulting program object has a program target given by <target> and is assigned target-specific default values (see section 3.11.8 for fragment programs). BindProgramARB may also be used to bind an existing program object to a program target. If <program> is zero, the default program object for <target> is bound. If <program> is the name of an existing program object whose associated program target is <target>, the named program object is bound. The error INVALID_OPERATION is generated if <program> names an existing program object whose associated program target is anything other than <target>.

Programs objects are deleted by calling

```
  void DeleteProgramsARB(sizei n, const uint *programs);
```

<programs> contains <n> names of programs to be deleted. After a program object is deleted, its name is again unused. If a program object that is bound to any target is deleted, it is as though BindProgramARB is first executed with same target and a <program> of zero. Unused names in <programs> are silently ignored, as is the value zero.

The command

```
  void GenProgramsARB(sizei n, uint *programs);
```

returns <n> currently unused program names in <programs>. These names are marked as used, for the purposes of GenProgramsARB only, but objects are created only when they are first bound using BindProgramARB.

3.11.2 Fragment Program Grammar and Semantic Restrictions

Fragment program strings are specified as an array of ASCII characters containing the program text. When a fragment program is loaded by a call to ProgramStringARB, the program string is parsed into a set of tokens possibly separated by whitespace. Spaces, tabs, newlines, carriage returns, and comments are considered whitespace. Comments begin with the character "#" and are terminated by a newline, a carriage return, or the end of the program array.

The Backus-Naur Form (BNF) grammar below specifies the syntactically valid sequences for fragment programs. The set of valid tokens can be inferred from the grammar. The token "" represents an empty string and is used to indicate optional rules. A program is invalid if it contains any undefined tokens or characters.

A fragment program is required to begin with the header string "!!ARBfp1.0", without any preceding whitespace. This string

```
    identifies the subsequent program text as a fragment program
    (version 1.0) that should be parsed according to the following
    grammar and semantic rules.  Program string parsing begins with the
    character immediately following the header string.

    <program>              ::= <optionSequence> <statementSequence> "END"

    <optionSequence>       ::= <optionSequence> <option>
                             | ""

    <option>               ::= "OPTION" <identifier> ";"

    <statementSequence>    ::= <statementSequence> <statement>
                             | ""

    <statement>            ::= <instruction> ";"
                             | <namingStatement> ";"

    <instruction>          ::= <ALUInstruction>
                             | <TexInstruction>

    <ALUInstruction>       ::= <VECTORop_instruction>
                             | <SCALARop_instruction>
                             | <BINSCop_instruction>
                             | <BINop_instruction>
                             | <TRIop_instruction>
                             | <SWZ_instruction>

    <TexInstruction>       ::= <SAMPLE_instruction>
                             | <KIL_instruction>

    <VECTORop_instruction> ::= <VECTORop> <maskedDstReg> ","
                               <vectorSrcReg>

    <VECTORop>             ::= "ABS" | "ABS_SAT"
                             | "FLR" | "FLR_SAT"
                             | "FRC" | "FRC_SAT"
                             | "LIT" | "LIT_SAT"
                             | "MOV" | "MOV_SAT"

    <SCALARop_instruction> ::= <SCALARop> <maskedDstReg> ","
                               <scalarSrcReg>

    <SCALARop>             ::= "COS" | "COS_SAT"
                             | "EX2" | "EX2_SAT"
                             | "LG2" | "LG2_SAT"
                             | "RCP" | "RCP_SAT"
                             | "RSQ" | "RSQ_SAT"
                             | "SIN" | "SIN_SAT"
                             | "SCS" | "SCS_SAT"

    <BINSCop_instruction>  ::= <BINSCop> <maskedDstReg> ","
                               <scalarSrcReg> "," <scalarSrcReg>

    <BINSCop>              ::= "POW" | "POW_SAT"
    <BINop_instruction>    ::= <BINop> <maskedDstReg> ","
                               <vectorSrcReg> "," <vectorSrcReg>

    <BINop>                ::= "ADD" | "ADD_SAT"
                             | "DP3" | "DP3_SAT"
                             | "DP4" | "DP4_SAT"
                             | "DPH" | "DPH_SAT"
                             | "DST" | "DST_SAT"
                             | "MAX" | "MAX_SAT"
                             | "MIN" | "MIN_SAT"
                             | "MUL" | "MUL_SAT"
                             | "SGE" | "SGE_SAT"
                             | "SLT" | "SLT_SAT"
                             | "SUB" | "SUB_SAT"
                             | "XPD" | "XPD_SAT"

    <TRIop_instruction>    ::= <TRIop> <maskedDstReg> ","
                               <vectorSrcReg> "," <vectorSrcReg> ","
                               <vectorSrcReg>

    <TRIop>                ::= "CMP" | "CMP_SAT"
                             | "LRP" | "LRP_SAT"
                             | "MAD" | "MAD_SAT"

    <SWZ_instruction>      ::= <SWZop> <maskedDstReg> ","
                               <srcReg> "," <extendedSwizzle>

    <SWZop>                ::= "SWZ" | "SWZ_SAT"

    <SAMPLE_instruction>   ::= <SAMPLEop> <maskedDstReg> ","
                               <vectorSrcReg> "," <texImageUnit> ","
                               <texTarget>

    <SAMPLEop>             ::= "TEX" | "TEX_SAT"
                             | "TXP" | "TXP_SAT"
                             | "TXB" | "TXB_SAT"

    <KIL_instruction>      ::= "KIL" <vectorSrcReg>

    <texImageUnit>         ::= "texture" <optTexImageUnitNum>

    <texTarget>            ::= "1D"
                             | "2D"
                             | "3D"
                             | "CUBE"
                             | "RECT"

    <optTexImageUnitNum>   ::= ""
                             | "[" <texImageUnitNum> "]"

    <texImageUnitNum>      ::= <integer> from 0 to
                               MAX_TEXTURE_IMAGE_UNITS_ARB-1

    <scalarSrcReg>         ::= <optionalSign> <srcReg> <scalarSuffix>

    <vectorSrcReg>         ::= <optionalSign> <srcReg> <optionalSuffix>
    <maskedDstReg>          ::= <dstReg> <optionalMask>

    <extendedSwizzle>       ::= <xyzwExtendedSwizzle>
                              | <rgbaExtendedSwizzle>

```

```
<establishedName>      ::= <identifier>

<identifier>           ::= see text
```

The <integer> rule matches an integer constant. The integer consists of a sequence of one or more digits ("0" through "9").

The <floatConstant> rule matches a floating-point constant consisting of an integer part, a decimal point, a fraction part, an "e" or "E", and an optionally signed integer exponent. The integer and fraction parts both consist of a sequence of one or more digits ("0" through "9"). Either the integer part or the fraction parts (not both) may be missing; either the decimal point or the "e" (or "E") and the exponent (not both) may be missing.

The <identifier> rule matches a sequence of one or more letters ("A" through "Z", "a" through "z"), digits ("0" through "9), underscores ("_"), or dollar signs ("$"); the first character must not be a number. Upper and lower case letters are considered different (names are case-sensitive). The following strings are reserved keywords and may not be used as identifiers:

```
ABS, ABS_SAT, ADD, ADD_SAT, ALIAS, ATTRIB, CMP, CMP_SAT, COS,
COS_SAT, DP3, DP3_SAT, DP4, DP4_SAT, DPH, DPH_SAT, DST, DST_SAT,
END, EX2, EX2_SAT, FLR, FLR_SAT, FRC, FRC_SAT, KIL, LG2,
LG2_SAT, LIT, LIT_SAT, LRP, LRP_SAT, MAD, MAD_SAT, MAX, MAX_SAT,
MIN, MIN_SAT, MOV, MOV_SAT, MUL, MUL_SAT, OPTION, OUTPUT, PARAM,
POW, POW_SAT, RCP, RCP_SAT, RSQ, RSQ_SAT, SIN, SIN_SAT, SCS,
SCS_SAT, SGE, SGE_SAT, SLT, SLT_SAT, SUB, SUB_SAT, SWZ, SWZ_SAT,
TEMP, TEX, TEX_SAT, TXB, TXB_SAT, TXP, TXP_SAT, XPD, XPD_SAT,
fragment, program, result, state, and texture.
```

The error INVALID_OPERATION is generated if a fragment program fails to load because it is not syntactically correct or for one of the semantic restrictions described in the following sections.

A successfully loaded fragment program is parsed into a sequence of instructions. Each instruction is identified by its tokenized name. The operation of these instructions when executed is defined in section 3.11.5.

A successfully loaded program string replaces the program string previously loaded into the specified program object. If the OUT_OF_MEMORY error is generated by ProgramStringARB, no change is made to the previous contents of the current program object.

3.11.3 Fragment Program Variables

Fragment programs may access a number of different variables during their execution. The following sections define the variables that can be declared and used by a fragment program.

Explicit variable declarations allow a fragment program to establish a variable name that can be used to refer to a specified resource in subsequent instructions. A fragment program will fail to load if it declares the same variable name more than once or if it refers to a variable name that has not been previously declared in the program string.

Implicit variable declarations allow a fragment program to use the name of certain available resources by name.

3.11.3.1 Fragment Attributes

Fragment program attribute variables are a set of four-component floating-point vectors holding the attributes of the fragment being processed. Fragment attribute variables are read-only during fragment program execution.

Fragment attribute variables can be declared explicitly using the <ATTRIB_statement> grammar rule, or implicitly using the <fragAttribBinding> grammar rule in an executable instruction.

Each fragment attribute variable is bound to a single item of fragment state according to the <fragAttrBinding> grammar rule. The set of GL state that can be bound to a fragment attribute variable is given in Table X.1. Fragment attribute variables are initialized at each fragment program invocation with the current values of the bound state.

Fragment Attribute Binding	Components	Underlying State
fragment.color	(r,g,b,a)	primary color
fragment.color.primary	(r,g,b,a)	primary color
fragment.color.secondary	(r,g,b,a)	secondary color
fragment.texcoord	(s,t,r,q)	texture coordinate, unit 0
fragment.texcoord[n]	(s,t,r,q)	texture coordinate, unit n
fragment.fogcoord	(f,0,0,1)	fog distance/coordinate
fragment.position	(x,y,z,1/w)	window position

Table X.1: Fragment Attribute Bindings. The "Components" column indicates the mapping of the state in the "Underlying State" column. Bindings containing "[n]" require an integer value of <n> to select an individual item.

If a fragment attribute binding matches "fragment.color" or "fragment.color.primary", the "x", "y", "z", and "w" components of the fragment attribute variable are filled with the "r", "g", "b", and "a" components, respectively, of the fragment color. Each fixed-point color component undergoes an implied conversion to floating point. This conversion must leave the values 0 and 1 invariant.

If a fragment attribute binding matches "fragment.color.secondary", the "x", "y", "z", and "w" components of the fragment attribute variable are filled with the "r", "g", "b", and "a" components, respectively, of the fragment secondary color. Each fixed-point color component undergoes an implied conversion to floating point. This conversion must leave the values 0 and 1 invariant.

If a fragment attribute binding matches "fragment.texcoord" or "fragment.texcoord[n]", the "x", "y", "z", and "w" components of the fragment attribute variable are filled with the "s", "t", "r", and "q" components, respectively, of the fragment texture coordinates for texture unit <n>. If "[n]" is omitted, texture unit zero is used.

If a fragment attribute binding matches "fragment.fogcoord", the "x" component of the fragment attribute variable is filled with either the fragment eye distance or the fog coordinate, depending on whether the fog source is set to FRAGMENT_DEPTH_EXT or FOG_COORDINATE_EXT, respectively. The "y", "z", and "w" coordinates are filled with 0, 0, and 1, respectively.

If a fragment attribute binding matches "fragment.position", the "x" and "y" components of the fragment attribute variable are filled with the (x,y) window coordinates of the fragment center, relative to the lower left corner of the window. The "z" component is filled with the fragment's z window coordinate. This z window coordinate undergoes an implied conversion to floating point. This conversion must leave the values 0 and 1 invariant. The "w" component is filled with the reciprocal of the fragment's clip w coordinate.

On some implementations, the components of fragment.position may be generated by interpolating per-vertex position values. This may produce x and y window coordinates that don't exactly match those of the fragment center and z window coordinates that do not exactly match those generated by fixed-function rasterization. Therefore, there is no guaranteed invariance between the final z window coordinates of fragments processed by fragment programs that write depth values and fragments processed by any other means, even if the fragment programs in question simply copy the z value from the fragment.position binding.

3.11.3.2 Fragment Program Parameters

Fragment program parameter variables are a set of four-component floating-point vectors used as constants during fragment program execution. Fragment program parameters retain their values across fragment program invocations, although their values can change between invocations due to GL state changes.

Single program parameter variables and arrays of program parameter variables can be declared explicitly using the <PARAM_statement> grammar rule. Single program parameter variables can also be declared implicitly using the <paramSingleItemUse> grammar rule in an executable instruction.

Each single program parameter variable is bound to a constant vector or to a GL state vector according to the <paramSingleInit> grammar rule. Individual items of a program parameter array are bound to constant vectors or GL state vectors according to the <programMultipleInit> grammar rule. The set of GL state that can be bound to program parameter variables are given in Tables X.2.1 through X.2.4.

Constant Bindings

A program parameter variable can be bound to a scalar or vector constant using the <paramConstDecl> grammar rule (explicit declarations) or the <paramConstUse> grammar rule (implicit declarations).

If a program parameter binding matches the <paramConstScalarDecl> or <paramConstScalarUse> grammar rules, the corresponding program parameter variable is bound to the vector (X,X,X,X), where X is the value of the specified constant. Note that the <paramConstScalarUse> grammar rule, used only in implicit declarations, allows only non-negative constants. This disambiguates cases like "-2", which could conceivably be taken to mean either the vector "(2,2,2,2)" with all components negated or "(-2,-2,-2,-2)" without negation. Only the former interpretation is allowed by the grammar.

If a program parameter binding matches <paramConstVector>, the corresponding program parameter variable is bound to the vector (X,Y,Z,W), where X, Y, Z, and W are the values corresponding to the first, second, third, and fourth match of <signedFloatConstant>. If fewer than four constants are specified, Y, Z, and W assume the values 0.0, 0.0, and 1.0, if their respective constants are not specified.

Program parameter variables initialized to constant values can never be modified.

Program Environment/Local Parameter Bindings

Binding	Components	Underlying State
program.env[a]	(x,y,z,w)	program environment parameter a
program.local[a]	(x,y,z,w)	program local parameter a
program.env[a..b]	(x,y,z,w)	program environment parameters a through b
program.local[a..b]	(x,y,z,w)	program local parameters a through b

Table X.2.1: Program Environment/Local Parameter Bindings. <a> and <b> indicate parameter numbers, where <a> must be less than or equal to <b>.

If a program parameter binding matches "program.env[a]" or "program.local[a]", the four components of the program parameter variable are filled with the four components of program environment parameter <a> or program local parameter <a>, respectively.

Additionally, for program parameter array bindings, "program.env[a..b]" and "program.local[a..b]" are equivalent to specifying program environment parameters <a> through <b> in order or program local parameters <a> through <b> in order, respectively. In either case, a program will fail to load if <a> is greater than <b>.

Material Property Bindings

Binding	Components	Underlying State
state.material.ambient	(r,g,b,a)	front ambient material color
state.material.diffuse	(r,g,b,a)	front diffuse material color
state.material.specular	(r,g,b,a)	front specular material color
state.material.emission	(r,g,b,a)	front emissive material color
state.material.shininess	(s,0,0,1)	front material shininess
state.material.front.ambient	(r,g,b,a)	front ambient material color
state.material.front.diffuse	(r,g,b,a)	front diffuse material color
state.material.front.specular	(r,g,b,a)	front specular material color
state.material.front.emission	(r,g,b,a)	front emissive material color
state.material.front.shininess	(s,0,0,1)	front material shininess
state.material.back.ambient	(r,g,b,a)	back ambient material color
state.material.back.diffuse	(r,g,b,a)	back diffuse material color
state.material.back.specular	(r,g,b,a)	back specular material color
state.material.back.emission	(r,g,b,a)	back emissive material color
state.material.back.shininess	(s,0,0,1)	back material shininess

Table X.2.2: Material Property Bindings. If a material face is not specified in the binding, the front property is used.

If a program parameter binding matches any of the material properties listed in Table X.2.2, the program parameter variable is filled according to the table. For ambient, diffuse, specular, or emissive colors, the "x", "y", "z", and "w" components are filled with the "r", "g", "b", and "a" components, respectively, of the corresponding material color. For material shininess, the "x" component is filled with the material's specular exponent, and the "y", "z", and "w" components are filled with 0, 0, and 1, respectively. Bindings containing ".back" refer to the back material; all other bindings refer to the front material.

Material properties can be changed inside a Begin/End pair, either directly by calling Material, or indirectly through color material. However, such property changes are not guaranteed to update program parameter bindings until the following End command. Program parameter variables bound to material properties changed inside a Begin/End pair are undefined until the following End command.

Light Property Bindings

Binding	Components	Underlying State
state.light[n].ambient	(r,g,b,a)	light n ambient color
state.light[n].diffuse	(r,g,b,a)	light n diffuse color
state.light[n].specular	(r,g,b,a)	light n specular color
state.light[n].position	(x,y,z,w)	light n position
state.light[n].attenuation	(a,b,c,e)	light n attenuation constants and spot light exponent
state.light[n].spot.direction	(x,y,z,c)	light n spot direction and cutoff angle cosine
state.light[n].half	(x,y,z,1)	light n infinite half-angle
state.lightmodel.ambient	(r,g,b,a)	light model ambient color
state.lightmodel.scenecolor	(r,g,b,a)	light model front scene color
state.lightmodel . front.scenecolor	(r,g,b,a)	light model front scene color
state.lightmodel . back.scenecolor	(r,g,b,a)	light model back scene color
state.lightprod[n].ambient	(r,g,b,a)	light n / front material ambient color product
state.lightprod[n].diffuse	(r,g,b,a)	light n / front material diffuse color product
state.lightprod[n].specular	(r,g,b,a)	light n / front material specular color product
state.lightprod[n]. front.ambient	(r,g,b,a)	light n / front material ambient color product
state.lightprod[n]. front.diffuse	(r,g,b,a)	light n / front material diffuse color product
state.lightprod[n]. front.specular	(r,g,b,a)	light n / front material specular color product
state.lightprod[n]. back.ambient	(r,g,b,a)	light n / back material ambient color product
state.lightprod[n]. back.diffuse	(r,g,b,a)	light n / back material diffuse color product
state.lightprod[n]. back.specular	(r,g,b,a)	light n / back material specular color product

Table X.2.3: Light Property Bindings. <n> indicates a light number.

If a program parameter binding matches "state.light[n].ambient", "state.light[n].diffuse", or "state.light[n].specular", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "r", "g", "b", and "a" components, respectively, of the corresponding light color.

If a program parameter binding matches "state.light[n].position", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "x", "y", "z", and "w" components, respectively, of the light position.

If a program parameter binding matches "state.light[n].attenuation", the "x", "y", and "z" components of the program parameter variable are filled with the constant, linear, and quadratic attenuation parameters of the specified light, respectively (section 2.13.1).

The "w" component of the program parameter variable is filled with the spot light exponent of the specified light.

If a program parameter binding matches "state.light[n].spot.direction", the "x", "y", and "z" components of the program parameter variable are filled with the "x", "y", and "z" components of the spot light direction of the specified light, respectively (section 2.13.1). The "w" component of the program parameter variable is filled with the cosine of the spot light cutoff angle of the specified light.

If a program parameter binding matches "state.light[n].half", the "x", "y", and "z" components of the program parameter variable are filled with the x, y, and z components, respectively, of the normalized infinite half-angle vector

```
  h_inf = || P + (0, 0, 1) ||.
```

The "w" component is filled with 1. In the computation of h_inf, P consists of the x, y, and z coordinates of the normalized vector from the eye position P_e to the eye-space light position P_pli (section 2.13.1). h_inf is defined to correspond to the normalized half-angle vector when using an infinite light (w coordinate of the position is zero) and an infinite viewer (v_bs is FALSE). For local lights or a local viewer, h_inf is well-defined but does not match the normalized half-angle vector, which will vary depending on the vertex position.

If a program parameter binding matches "state.lightmodel.ambient", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "r", "g", "b", and "a" components of the light model ambient color, respectively.

If a program parameter binding matches "state.lightmodel.scenecolor" or "state.lightmodel.front.scenecolor", the "x", "y", and "z" components of the program parameter variable are filled with the "r", "g", and "b" components respectively of the "front scene color"

```
  c_scene = a_cs * a_cm + e_cm,
```

where a_cs is the light model ambient color, a_cm is the front ambient material color, and e_cm is the front emissive material color. The "w" component of the program parameter variable is filled with the alpha component of the front diffuse material color. If a program parameter binding matches "state.lightmodel.back.scenecolor", a similar back scene color, computed using back-facing material properties, is used. The front and back scene colors match the values that would be assigned to vertices using conventional lighting if all lights were disabled.

If a program parameter binding matches anything beginning with "state.lightprod[n]", the "x", "y", and "z" components of the program parameter variable are filled with the "r", "g", and "b" components, respectively, of the corresponding light product. The three light product components are the products of the corresponding color components of the specified material property and the light color of the specified light (see Table X.2.3). The "w" component of the program parameter variable is filled with the alpha component of the specified material property.

Light products depend on material properties, which can be changed inside a Begin/End pair. Such property changes are not guaranteed to take effect until the following End command. Program parameter variables bound to light products whose corresponding material property changes inside a Begin/End pair are undefined until the following End command.

Texture Environment Property Bindings

Binding	Components	Underlying State
state.texenv[n].color	(r,g,b,a)	texture environment n color

Table X.2.4: Texture Environment Property Bindings. "[n]" is optional -- texture unit <n> is used if specified; texture unit 0 is used otherwise.

If a program parameter binding matches "state.texenv[n].color", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "r", "g", "b", and "a" components, respectively, of the corresponding texture environment color. Note that only "legacy" texture units, as queried by MAX_TEXTURE_UNITS, include texture environment state. Texture image units and texture coordinate sets do not have associated texture environment state.

Fog Property Bindings

Binding	Components	Underlying State
state.fog.color	(r,g,b,a)	RGB fog color (section 3.11)
state.fog.params	(d,s,e,r)	fog density, linear start and end, and 1/(end-start) (section 3.11)

Table X.2.5: Fog Property Bindings

If a program parameter binding matches "state.fog.color", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "r", "g", "b", and "a" components, respectively, of the fog color (section 3.11).

If a program parameter binding matches "state.fog.params", the "x", "y", and "z" components of the program parameter variable are filled with the fog density, linear fog start, and linear fog end parameters (section 3.11), respectively. The "w" component is filled with 1/(end-start), where end and start are the linear fog end and start parameters, respectively.

Depth Property Bindings

Binding	Components	Underlying State
state.depth.range	(n,f,d,1)	Depth range near, far, and (far-near) (section 2.10.1)

Table X.2.6: Depth Property Bindings

If a program parameter binding matches "state.depth.range", the "x" and "y" components of the program parameter variable are filled with the mappings of near and far clipping planes to window coordinates, respectively. The "z" component is filled with the difference of the mappings of near and far clipping planes, far minus near. The "w" component is filled with 1.

Matrix Property Bindings

Binding	Underlying State
* state.matrix.modelview[n]	modelview matrix n
state.matrix.projection	projection matrix
state.matrix.mvp	modelview-projection matrix
* state.matrix.texture[n]	texture matrix n
state.matrix.palette[n]	modelview palette matrix n
state.matrix.program[n]	program matrix n

Table X.2.7: Base Matrix Property Bindings. The "[n]" syntax indicates a specific matrix number. For modelview and texture matrices, a matrix number is optional, and matrix zero will be used if the matrix number is omitted. These base bindings may further be modified by a inverse/transpose selector and a row selector.

If the beginning of a program parameter binding matches any of the matrix binding names listed in Table X.2.7, the binding corresponds to a 4x4 matrix. If the parameter binding is followed by ".inverse", ".transpose", or ".invtrans" (<stateMatModifier> grammar rule), the inverse, transpose, or transpose of the inverse, respectively, of the matrix specified in Table X.2.7 is selected. Otherwise, the matrix specified in Table X.2.7 is selected. If the specified matrix is poorly-conditioned (singular or nearly so), its inverse matrix is undefined. The binding name "state.matrix.mvp" refers to the product of modelview matrix zero and the projection matrix, defined as

```
 MVP = P * M0,
```

where P is the projection matrix and M0 is modelview matrix zero.

If the selected matrix is followed by ".row[<a>]" (matching the <stateMatrixRow> grammar rule), the "x", "y", "z", and "w" components of the program parameter variable are filled with the four entries of row <a> of the selected matrix. In the example,

```
PARAM m0 = state.matrix.modelview[1].row[0];
PARAM m1 = state.matrix.projection.transpose.row[3];
```

the variable "m0" is set to the first row (row 0) of modelview matrix 1 and "m1" is set to the last row (row 3) of the transpose of the projection matrix.

For program parameter array bindings, multiple rows of the selected matrix can be bound via the <stateMatrixRows> grammar rule. If the selected matrix binding is followed by ".row[<a>..<b>]", the result is equivalent to specifying matrix rows <a> through <b>, in order. A program will fail to load if <a> is greater than <b>. If no row selection is specified (<optMatrixRows> matches ""), matrix rows 0 through 3 are bound in order. In the example,

```
  PARAM m2[] = { state.matrix.program[0].row[1..2] };
  PARAM m3[] = { state.matrix.program[0].transpose };
```

the array "m2" has two entries, containing rows 1 and 2 of program matrix zero, and "m3" has four entries, containing all four rows of the transpose of program matrix zero.

Program Parameter Arrays

A program parameter array variable can be declared explicitly by matching the <PARAM_multipleStmt> grammar rule. Programs can optionally specify the number of individual program parameters in the array, using the <optArraySize> grammar rule. Program parameter arrays may not be declared implicity.

Individual parameter variables in a program parameter array are bound to GL state vectors or constant vectors as specified by the grammar rule <paramMultInitList>. Each individual parameter in the array is bound in turn as described above.

The total number of entries in the array is equal to the number of parameters bound in the initializer list. A fragment program that specifies an array size (<optArraySize> matches <integer>) that does not match the number of parameter bindings in the initialization list will fail to load.

Program parameter array variables may only be accessed using absolute addressing by matching the <progParamArrayAbs> grammar rule. Array accesses are checked against the limits of the array. If any fragment program instruction accesses a program parameter array with an out-of-range index (greater than or equal to the size of the array), the fragment program will fail to load.

Individual state vectors can have no more than one unique binding in any given program. The GL will automatically combine multiple bindings of the same state vector into a single unique binding.

3.11.3.3 Fragment Program Temporaries

Fragment program temporary variables are a set of four-component floating-point vectors used to hold temporary results during fragment program execution. Temporaries do not persist between program invocations, and are undefined at the beginning of each fragment program invocation.

Fragment program temporary variables can be declared explicitly using the <TEMP_statement> grammar rule. Each such statement can declare one or more temporaries. Fragment program temporary variables can not be declared implicitly.

3.11.3.4 Fragment Program Results

Fragment program result variables are a set of four component floating-point vectors used to hold the final results of a fragment program. Fragment program result variables are write-only during fragment program execution.

Fragment program result variables can be declared explicitly using the <OUTPUT_statement> grammar rule, or implicitly using the <resultBinding> grammar rule in an executable instruction. Each fragment program result variable is bound to a fragment attribute used in subsequent back-end processing. The set of fragment program result variable bindings is given in Table X.3.

Binding	Components	Description
result.color	(r,g,b,a)	color
result.depth	(*,*,d,*)	depth coordinate

Table X.3: Fragment Result Variable Bindings. Components labeled "*" are unused.

If a result variable binding matches "result.color", updates to the "x", "y", "z", and "w" components of the result variable modify the "r", "g", "b", and "a" components, respectively, of the fragment's output color. If "result.color" is not both bound by the fragment program and written by some instruction of the program, the output color of the fragment program is undefined.

If a result variable binding matches "result.depth", updates to the "z" component of the result variable modify the fragment's output depth value. If "result.depth" is not both bound by the fragment program and written by some instruction of the program, the interpolated depth value produced by rasterization is used as if fragment program mode is not enabled. Writes to any component of depth other than the "z" component have no effect.

3.11.3.5 Fragment Program Aliases

Fragment programs can create aliases by matching the <ALIAS_statement> grammar rule. Aliases allow programs to use multiple variable names to refer to a single underlying variable. For example, the statement

```
ALIAS var1 = var0
```

establishes a variable name named "var1". Subsequent references to "var1" in the program text are treated as references to "var0". The left hand side of an ALIAS statement must be a new variable name, and the right hand side must be an established variable name.

Aliases are not considered variable declarations, so do not count against the limits on the number of variable declarations allowed in the program text.

3.11.3.6 Fragment Program Resource Limits

The fragment program execution environment provides implementation-dependent resource limits on the number of ALU instructions, texture instructions, total instructions (ALU or texture), temporary variable declarations, program parameter bindings, or texture indirections. A program that exceeds any of these resource limits will fail to load. The resource limits for fragment programs can be queried by calling GetProgramiv (section 6.1.12) with a target of FRAGMENT_PROGRAM_ARB.

The limit on fragment program ALU instructions can be queried with a <pname> of MAX_PROGRAM_ALU_INSTRUCTIONS_ARB, and must be at least 48. Each ALU instruction in the program (matches of the <ALUInstruction> grammar rule) counts against this limit.

The limit on fragment program texture instructions can be queried with a <pname> of MAX_PROGRAM_TEX_INSTRUCTIONS_ARB, and must be at least 24. Each texture instruction in the program (matches of the <TexInstruction> grammar rule) counts against this limit.

The limit on fragment program total instructions can be queried with a <pname> of MAX_PROGRAM_INSTRUCTIONS_ARB, and must be at least 72. Each instruction in the program (matching the <instruction> grammar rule) counts against this limit. Note that the limit on total instructions is not necessarily equal to the sum of the limits on ALU instructions and texture instructions.

The limit on fragment program texture indirections can be queried with a <pname> of MAX_PROGRAM_TEX_INDIRECTIONS_ARB, and must be at least 4. Texture indirections are described in 3.11.6. If an implementation has no limit on texture indirections, the limit will be equal to the limit on texture instructions.

The limit on fragment program temporary variable declarations can be queried with a <pname> of MAX_PROGRAM_TEMPORARIES_ARB, and must be at least 16. Each temporary declared in the program, using the <TEMP_statement> grammar rule, counts against this limit. Aliases of declared temporaries do not.

The limit on fragment program attribute bindings can be queried with a <pname> of MAX_PROGRAM_ATTRIBS_ARB and must be at least 10. Each distinct vertex attribute bound explicitly or implicitly in the program counts against this limit; vertex attributes bound multiple times count only once.

The limit on fragment program parameter bindings can be queried with a <pname> of MAX_PROGRAM_PARAMETERS_ARB, and must be at least 24. Each distinct GL state vector bound explicitly or implicitly in the program counts against this limit; GL state vectors bound multiple times count only once. Every other constant vector bound in the program is counted if and only if an identical constant vector has not already been counted. Two constant vectors are considered identical if the four component values are numerically equivalent. Recall that scalar constants bound in a program are treated as vector constants with the scalar value replicated.

In addition to the limits described above, the GL provides a similar set of implementation-dependent native resource limits. These limits, specified in Section 6.1.12, provide guidance as to whether the program is small enough to use a "native" mode where fragment programs may be executed with higher performance. The native resource limits and usage counts are implementation-dependent and may not exactly correspond to limits and counts described above. A program's native resource consumption may be reduced by program optimizations performed by the GL. Native resource consumption may be increased due to emulation of instructions or any other program features not natively supported by an implementation. Notably, an additional texture indirection may be consumed due to an implementation's lack of native support for texture instructions with source coordinate swizzles or parameter source coordinates, which may require emulation by prepending ALU instructions. An implementation may also fail to natively support all combinations of attributes described in Table X.1, even if the total number of bound attributes is fewer than the native attribute limit. In this case the program is still considered to exceed the native resource limits, as queried by PROGRAM_UNDER_NATIVE_LIMITS_ARB (section 6.1.12).

To assist in resource counting, the GL additionally provides GetProgram queries to determine the resource usage and native resource usage of the currently bound program, and to determine whether the bound program exceeds any native resource limit.

Programs that exceed any native resource limit may or may not load depending on the implementation.

3.11.4 Fragment Program Execution Environment

If fragment program mode is enabled, the currently bound fragment program is executed when any fragment is produced by rasterization.

If fragment program mode is enabled and the currently bound program object does not contain a valid fragment program, the error INVALID_OPERATION will be generated by Begin, RasterPos, and any command that implicitly calls Begin (e.g., DrawArrays).

Fragment programs execute a sequence of instructions without branching. Fragment programs begin by executing the first instruction in the program, and execute instructions in the order specified in the program until the last instruction is completed.

There are 33 fragment program instructions. The instructions and their respective input and output parameters are summarized in Table X.5.

Instruction	Inputs	Output	Description
ABS	v	v	absolute value
ADD	v,v	v	add
CMP	v,v,v	v	compare
COS	s	ssss	cosine with reduction to [-PI,PI]
DP3	v,v	ssss	3-component dot product
DP4	v,v	ssss	4-component dot product
DPH	v,v	ssss	homogeneous dot product
DST	v,v	v	distance vector
EX2	s	ssss	exponential base 2
FLR	v	v	floor
FRC	v	v	fraction
KIL	v	v	kill fragment
LG2	s	ssss	logarithm base 2
LIT	v	v	compute light coefficients
LRP	v,v,v	v	linear interpolation
MAD	v,v,v	v	multiply and add
MAX	v,v	v	maximum
MIN	v,v	v	minimum
MOV	v	v	move
MUL	v,v	v	multiply
POW	s,s	ssss	exponentiate
RCP	s	ssss	reciprocal
RSQ	s	ssss	reciprocal square root
SCS	s	ss--	sine/cosine without reduction
SGE	v,v	v	set on greater than or equal
SIN	s	ssss	sine with reduction to [-PI,PI]
SLT	v,v	v	set on less than
SUB	v,v	v	subtract
SWZ	v	v	extended swizzle
TEX	v,u,t	v	texture sample
TXB	v,u,t	v	texture sample with bias
TXP	v,u,t	v	texture sample with projection
XPD	v,v	v	cross product

Table X.5: Summary of fragment program instructions. "v" indicates a floating-point vector input or output, "s" indicates a floating-point scalar input, "ssss" indicates a scalar output replicated across a 4-component result vector, "ss--" indicates two scalar outputs in the first two components, "u" indicates a texture image unit identifier, and "t" indicates a texture target.

3.11.4.1 Fragment Program Operands

Most fragment program instructions operate on floating-point vectors or scalars, as indicated by the grammar rules <vectorSrcReg> and <scalarSrcReg>, respectively.

Vector and scalar operands can be obtained from fragment attribute, program parameter, or temporary registers, as indicated by the <srcReg> rule. For scalar operands, a single vector component is selected by the <scalarSuffix> rule, where the characters "x", "y", "z", and "w", or "r", "g", "b", and "a" select the first, second, third, and fourth components, respectively, of the vector.

Vector operands can be swizzled according to the <optionalSuffix> rule. In its most general form, the <optionalSuffix> rule matches the pattern ".????" where each question mark is replaced with one of "x", "y", "z", "w", "r", "g", "b", or "a". For such patterns, the first, second, third, and fourth components of the operand are taken from the vector components named by the first, second, third, and fourth character of the pattern, respectively. For example, if the swizzle suffix is ".yzzx" or ".gbbr" and the specified source contains {2,8,9,0}, the swizzled operand used by the instruction is {8,9,9,2}.

If the <optionalSuffix> rule matches "", it is treated as though it were ".xyzw". If the <optionalSuffix> rule matches (ignoring whitespace) ".x", ".y", ".z", or ".w", these are treated the same as ".xxxx", ".yyyy", ".zzzz", and ".wwww" respectively. Likewise, if the <optionalSuffix> rule matches ".r", ".g", ".b", or ".a", these are treated the same as ".rrrr", ".gggg", ".bbbb", and ".aaaa" respectively.

Floating-point scalar or vector operands can optionally be negated according to the <optionalSign> rule in <scalarSrcReg> and <vectorSrcReg>. If the <optionalSign> matches "-", each operand or operand component is negated.

The following pseudo-code spells out the operand generation process. In the example, "float" is a floating-point scalar type, while "floatVec" is a four-component vector. "source" refers to the register used for the operand, matching the <srcReg> rule. "negate" is TRUE if the <optionalSign> rule in <scalarSrcReg> or <vectorSrcReg> matches "-" and FALSE otherwise. The ".c***", ".*c**", ".**c*", ".***c" modifiers refer to the x, y, z, and w components obtained by the swizzle operation; the ".c" modifier refers to the single component selected for a scalar load.

```
floatVec VectorLoad(floatVec source)
{
    floatVec operand;

    operand.x = source.c***;
    operand.y = source.*c**;
    operand.z = source.**c*;
    operand.w = source.***c;
    if (negate) {
       operand.x = -operand.x;
       operand.y = -operand.y;
       operand.z = -operand.z;
       operand.w = -operand.w;
    }

    return operand;
}
```

```
  float ScalarLoad(floatVec source)
  {
      float operand;

      operand = source.c;
      if (negate) {
        operand = -operand;
      }

      return operand;
  }
```

3.11.4.2 Fragment Program Parameter Arrays

A fragment program can load a single element of a program parameter array using only absolute addressing. Program parameter arrays are accessed when the <progParamArrayAbs> rule is matched. The offset of the selected entry in the array is given by the number matching <progParamRegNum>. If the offset exceeds the size of the array, the results of the access are undefined, but may not lead to program or GL termination.

3.11.4.3 Fragment Program Destination Register Update

Fragment program instructions write a 4-component result vector to a single temporary or fragment result register. Writes to individual components of the destination register are controlled by individual component write masks specified as part of the instruction. Optional clamping of each component of the destination register to the range [0,1] is controlled by an opcode modifier.

The component write mask is specified by the <optionalMask> rule found in the <maskedDstReg> rule. If the optional mask is "", all components are enabled. Otherwise, the optional mask names the individual components to enable. The characters "x", "y", "z", and "w", or "r", "g", "b", and "a" match the first, second, third, and fourth components, respectively. For example, an optional mask of ".xzw" indicates that the x, z, and w components should be enabled for writing but the y component should not. The grammar requires that the destination register mask components must be listed in "xyzw", or "rgba" order. Component names from one set (xyzw or rgba) cannot be mixed with component names from another set. For example, ".rgw" is not a valid writemask.

Each component of the destination register is updated with the result of the fragment program instruction if and only if the component is enabled for writes by the component write mask. Otherwise, the component of the destination register remains unchanged.

If the instruction opcode has the "_SAT" suffix, requesting saturated result vectors, each component of the result vector enabled in the writemask is clamped to the range [0,1] before being updated in the destination register.

The following pseudocode illustrates the process of writing a result vector to the destination register. In the pseudocode, "instrmask"

refers to the component write mask given by the <optionalMask> rule.
"clamp" is TRUE if the instruction specifies that the result should
be clamped. "result" and "destination" refer to the result vector
and the register selected by <dstReg>, respectively.

```
  void UpdateDestination(floatVec destination, floatVec result)
  {
      floatVec merged;

      // Clamp the result vector components to [0,1], if requested.
      if (instrClamp) {
          if (result.x < 0)      result.x = 0;
          else if (result.x > 1) result.x = 1;
          if (result.y < 0)      result.y = 0;
          else if (result.y > 1) result.y = 1;
          if (result.z < 0)      result.z = 0;
          else if (result.z > 1) result.z = 1;
          if (result.w < 0)      result.w = 0;
          else if (result.w > 1) result.w = 1;
      }

      // Merge the converted result into the destination register,
      // under control of the compile-time write mask.
      merged = destination;
      if (instrMask.x) {
          merged.x = result.x;
      }
      if (instrMask.y) {
          merged.y = result.y;
      }
      if (instrMask.z) {
          merged.z = result.z;
      }
      if (instrMask.w) {
          merged.w = result.w;
      }

      // Write out the new destination register.
      destination = merged;
  }
```

3.11.4.4 Fragment Program Result Processing

As a fragment program executes, it will write to either one or two
result registers that are mapped to the fragment's color and depth.

The fragment's color components are first clamped to the range [0,1]
then converted to fixed point as in section 2.13.9. If the fragment
program does not write result.color, the color will be undefined in
subsequent stages.

If the fragment program contains an instruction to write to
result.depth, the fragment's depth is replaced by the value of the
"z" component of result.depth. This z value is first clamped to the
range [0,1] then converted to fixed-point as if it were a window z
value (section 2.10.1). If the fragment program does not write
result.depth, the fragment's original depth is unmodified.

3.11.4.5 Fragment Program Options

The <optionSequence> grammar rule provides a mechanism for programs to indicate that one or more extended language features are used by the program. All program options used by the program must be declared at the beginning of the program string. Each program option specified in a program string will modify the syntactic or semantic rules used to interpet the program and the execution environment used to execute the program. Program options not present in the program string are ignored, even if they are supported by the GL.

The <identifier> token in the <option> rule must match the name of a program option supported by the implementation. To avoid option name conflicts, option identifiers are required to begin with a vendor prefix. A program will fail to load if it specifies a program option not supported by the GL.

Fragment program options should confine their semantic changes to the domain of fragment programs. Support for a fragment program option should not change the specification and behavior of fragment programs not requesting use of that option.

3.11.4.5.1 Fog Application Fragment Program Options

If a fragment program specifies one of the options "ARB_fog_exp", "ARB_fog_exp2", or "ARB_fog_linear", the program will apply fog to the program's final clamped color using a fog mode of EXP, EXP2, or LINEAR, respectively, as described in section 3.10.

When a fog option is specified in a fragment program, semantic restrictions are added to indicate that a fragment program will fail to load if the number of temporaries it contains exceeds the implementation-dependent limit minus 1, if the number of attributes it contains exceeds the implementation-dependent limit minus 1, or if the number of parameters it contains exceeds the implementation-dependent limit minus 2.

Additionally, when the ARB_fog_exp option is specified in a fragment program, a semantic restriction is added to indicate that a fragment program will fail to load if the number of instructions or ALU instructions it contains exceeds the implementation-dependent limit minus 3. When the ARB_fog_exp2 option is specified in a fragment program, a semantic restriction is added to indicate that a fragment program will fail to load if the number of instructions or ALU instructions it contains exceeds the implementation-dependent limit minus 4. When the ARB_fog_linear option is specified in a fragment program, a semantic restriction is added to indicate that a fragment program will fail to load if the number of instructions or ALU instructions it contains exceeds the implementation-dependent limit minus 2.

Only one fog application option may be specified by any given fragment program. A fragment program that specifies more than one of the program options "ARB_fog_exp", "ARB_fog_exp2", and "ARB_fog_linear", will fail to load.

3.11.4.5.2 Precision Hint Options

Fragment program computations are carried out at an implementation-dependent precision. However, some implementations may be able to perform fragment program computations at more than one precision, and may be able to trade off computation precision for performance.

If a fragment program specifies the "ARB_precision_hint_fastest" program option, implementations should select precision to minimize program execution time, with possibly reduced precision. If a fragment program specifies the "ARB_precision_hint_nicest" program option, implementations should maximize the precision, with possibly increased execution time.

Only one precision control option may be specified by any given fragment program. A fragment program that specifies both the "ARB_precision_hint_fastest" and "ARB_precision_hint_nicest" program options will fail to load.

3.11.5 Fragment Program ALU Instruction Set

The following sections describe the set of supported fragment program instructions. Each section contains pseudocode describing the instruction. Instructions will have up to three operands, referred to as "op0", "op1", and "op2". The operands are loaded using the mechanisms specified in section 3.11.4.1. The variables "tmp", "tmp0", "tmp1", and "tmp2" describe scalars or vectors used to hold intermediate results in the instruction. Instructions will generate a result vector called "result". The result vector is then written to the destination register specified in the instruction as described in section 3.11.4.3.

3.11.5.1 ABS: Absolute Value

The ABS instruction performs a component-wise absolute value operation on the single operand to yield a result vector.

```
  tmp = VectorLoad(op0);
  result.x = fabs(tmp.x);
  result.y = fabs(tmp.y);
  result.z = fabs(tmp.z);
  result.w = fabs(tmp.w);
```

3.11.5.2 ADD: Add

The ADD instruction performs a component-wise add of the two operands to yield a result vector.

```
tmp0 = VectorLoad(op0);
tmp1 = VectorLoad(op1);
result.x = tmp0.x + tmp1.x;
result.y = tmp0.y + tmp1.y;
result.z = tmp0.z + tmp1.z;
result.w = tmp0.w + tmp1.w;
```

The following rules apply to addition:

```
1. <x> + <y> == <y> + <x>, for all <x> and <y>.
2. <x> + 0.0 == <x>, for all <x>.
```

3.11.5.3 CMP: Compare

The CMP instructions performs a component-wise comparison of the first operand against zero, and copies the values of the second or third operands based on the results of the compare.

```
tmp0 = VectorLoad(op0);
tmp1 = VectorLoad(op1);
tmp2 = VectorLoad(op2);
result.x = (tmp0.x < 0.0) ? tmp1.x : tmp2.x;
result.y = (tmp0.y < 0.0) ? tmp1.y : tmp2.y;
result.z = (tmp0.z < 0.0) ? tmp1.z : tmp2.z;
result.w = (tmp0.w < 0.0) ? tmp1.w : tmp2.w;
```

3.11.5.4 COS: Cosine

The COS instruction approximates the trigonometric cosine of the angle specified by the scalar operand and replicates it to all four components of the result vector. The angle is specified in radians and does not have to be in the range [-PI,PI].

```
tmp = ScalarLoad(op0);
result.x = ApproxCosine(tmp);
result.y = ApproxCosine(tmp);
result.z = ApproxCosine(tmp);
result.w = ApproxCosine(tmp);
```

3.11.5.5 DP3: Three-Component Dot Product

The DP3 instruction computes a three-component dot product of the two operands (using the first three components) and replicates the dot product to all four components of the result vector.

```
tmp0 = VectorLoad(op0);
tmp1 = VectorLoad(op1);
dot = (tmp0.x * tmp1.x) + (tmp0.y * tmp1.y) + (tmp0.z * tmp1.z);
result.x = dot;
result.y = dot;
result.z = dot;
result.w = dot;
```

3.11.5.6 DP4: Four-Component Dot Product

The DP4 instruction computes a four-component dot product of the two operands and replicates the dot product to all four components of the result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1):
  dot = (tmp0.x * tmp1.x) + (tmp0.y * tmp1.y) +
        (tmp0.z * tmp1.z) + (tmp0.w * tmp1.w);
  result.x = dot;
  result.y = dot;
  result.z = dot;
  result.w = dot;
```

3.11.5.7 DPH: Homogeneous Dot Product

The DPH instruction computes a three-component dot product of the two operands (using the x, y, and z components), adds the w component of the second operand, and replicates the sum to all four components of the result vector. This is equivalent to a four-component dot product where the w component of the first operand is forced to 1.0.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1):
  dot = (tmp0.x * tmp1.x) + (tmp0.y * tmp1.y) +
        (tmp0.z * tmp1.z) + tmp1.w;
  result.x = dot;
  result.y = dot;
  result.z = dot;
  result.w = dot;
```

3.11.5.8 DST: Distance Vector

The DST instruction computes a distance vector from two specially-formatted operands. The first operand should be of the form [NA, d^2, d^2, NA] and the second operand should be of the form [NA, 1/d, NA, 1/d], where NA values are not relevant to the calculation and d is a vector length. If both vectors satisfy these conditions, the result vector will be of the form [1.0, d, d^2, 1/d].

The exact behavior is specified in the following pseudo-code:

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = 1.0;
  result.y = tmp0.y * tmp1.y;
  result.z = tmp0.z;
  result.w = tmp1.w;
```

Given an arbitrary vector, d^2 can be obtained using the DP3 instruction (using the same vector for both operands) and 1/d can be obtained from d^2 using the RSQ instruction.

This distance vector is useful for per-fragment light attenuation calculations: a DP3 operation using the distance vector and an attenuation constants vector as operands will yield the attenuation factor.

3.11.5.9 EX2: Exponential Base 2

The EX2 instruction approximates 2 raised to the power of the scalar operand and replicates the approximation to all four components of the result vector.

```
  tmp = ScalarLoad(op0);
  result.x = Approx2ToX(tmp);
  result.y = Approx2ToX(tmp);
  result.z = Approx2ToX(tmp);
  result.w = Approx2ToX(tmp);
```

3.11.5.10 FLR: Floor

The FLR instruction performs a component-wise floor operation on the operand to generate a result vector. The floor of a value is defined as the largest integer less than or equal to the value. The floor of 2.3 is 2.0; the floor of -3.6 is -4.0.

```
  tmp = VectorLoad(op0);
  result.x = floor(tmp.x);
  result.y = floor(tmp.y);
  result.z = floor(tmp.z);
  result.w = floor(tmp.w);
```

3.11.5.11 FRC: Fraction

The FRC instruction extracts the fractional portion of each component of the operand to generate a result vector. The fractional portion of a component is defined as the result after subtracting off the floor of the component (see FLR), and is always in the range [0.0, 1.0).

For negative values, the fractional portion is NOT the number written to the right of the decimal point -- the fractional portion of -1.7 is not 0.7 -- it is 0.3. 0.3 is produced by subtracting the floor of -1.7 (-2.0) from -1.7.

```
  tmp = VectorLoad(op0);
  result.x = fraction(tmp.x);
  result.y = fraction(tmp.y);
  result.z = fraction(tmp.z);
  result.w = fraction(tmp.w);
```

3.11.5.12 LG2: Logarithm Base 2

The LG2 instruction approximates the base 2 logarithm of the scalar operand and replicates it to all four components of the result vector.

```
  tmp = ScalarLoad(op0);
  result.x = ApproxLog2(tmp);
  result.y = ApproxLog2(tmp);
  result.z = ApproxLog2(tmp);
  result.w = ApproxLog2(tmp);
```

If the scalar operand is zero or negative, the result is undefined.

3.11.5.13 LIT: Light Coefficients

The LIT instruction accelerates per-fragment lighting by computing lighting coefficients for ambient, diffuse, and specular light contributions. The "x" component of the single operand is assumed to hold a diffuse dot product (n dot VP_pli, as in the vertex lighting equations in Section 2.13.1). The "y" component of the operand is assumed to hold a specular dot product (n dot h_i). The "w" component of the operand is assumed to hold the specular exponent of the material (s_rm), and is clamped to the range (-128, +128) exclusive.

The "x" component of the result vector receives the value that should be multiplied by the ambient light/material product (always 1.0). The "y" component of the result vector receives the value that should be multiplied by the diffuse light/material product (n dot VP_pli). The "z" component of the result vector receives the value that should be multiplied by the specular light/material product (f_i * (n dot h_i) ^ s_rm). The "w" component of the result is the constant 1.0.

Negative diffuse and specular dot products are clamped to 0.0, as is done in the standard per-vertex lighting operations. In addition, if the diffuse dot product is zero or negative, the specular coefficient is forced to zero.

```
  tmp = VectorLoad(op0);
  if (tmp.x < 0) tmp.x = 0;
  if (tmp.y < 0) tmp.y = 0;
  if (tmp.w < -(128.0-epsilon)) tmp.w = -(128.0-epsilon);
  else if (tmp.w > 128-epsilon) tmp.w = 128-epsilon;
  result.x = 1.0;
  result.y = tmp.x;
  result.z = (tmp.x > 0) ? RoughApproxPower(tmp.y, tmp.w) : 0.0;
  result.w = 1.0;
```

The exponentiation approximation function may be defined in terms of the base 2 exponentiation and logarithm approximation operations in the EX2 and LG2 instructions, where

```
  ApproxPower(a,b) = ApproxExp2(b * ApproxLog2(a)).
```

In particular, the approximation may not be any more accurate than the underlying EX2 and LG2 operations.

Also, since 0^0 is defined to be 1, RoughApproxPower(0.0, 0.0) will produce 1.0.

3.11.5.14 LRP: Linear Interpolation

The LRP instruction performs a component-wise linear interpolation between the second and third operands using the first operand as the blend factor.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  tmp2 = VectorLoad(op2);
  result.x = tmp0.x * tmp1.x + (1 - tmp0.x) * tmp2.x;
  result.y = tmp0.y * tmp1.y + (1 - tmp0.y) * tmp2.y;
  result.z = tmp0.z * tmp1.z + (1 - tmp0.z) * tmp2.z;
  result.w = tmp0.w * tmp1.w + (1 - tmp0.w) * tmp2.w;
```

3.11.5.15 MAD: Multiply and Add

The MAD instruction performs a component-wise multiply of the first two operands, and then does a component-wise add of the product to the third operand to yield a result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  tmp2 = VectorLoad(op2);
  result.x = tmp0.x * tmp1.x + tmp2.x;
  result.y = tmp0.y * tmp1.y + tmp2.y;
  result.z = tmp0.z * tmp1.z + tmp2.z;
  result.w = tmp0.w * tmp1.w + tmp2.w;
```

The multiplication and addition operations in this instruction are subject to the same rules as described for the MUL and ADD instructions.

3.11.5.16 MAX: Maximum

The MAX instruction computes component-wise maximums of the values in the two operands to yield a result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = (tmp0.x > tmp1.x) ? tmp0.x : tmp1.x;
  result.y = (tmp0.y > tmp1.y) ? tmp0.y : tmp1.y;
  result.z = (tmp0.z > tmp1.z) ? tmp0.z : tmp1.z;
  result.w = (tmp0.w > tmp1.w) ? tmp0.w : tmp1.w;
```

3.11.5.17 MIN: Minimum

The MIN instruction computes component-wise minimums of the values in the two operands to yield a result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = (tmp0.x > tmp1.x) ? tmp1.x : tmp0.x;
  result.y = (tmp0.y > tmp1.y) ? tmp1.y : tmp0.y;
  result.z = (tmp0.z > tmp1.z) ? tmp1.z : tmp0.z;
  result.w = (tmp0.w > tmp1.w) ? tmp1.w : tmp0.w;
```

3.11.5.18 MOV: Move

The MOV instruction copies the value of the operand to yield a result vector.

```
  result = VectorLoad(op0);
```

3.11.5.19 MUL: Multiply

The MUL instruction performs a component-wise multiply of the two operands to yield a result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = tmp0.x * tmp1.x;
  result.y = tmp0.y * tmp1.y;
  result.z = tmp0.z * tmp1.z;
  result.w = tmp0.w * tmp1.w;
```

The following rules apply to multiplication:

1. <x> * <y> == <y> * <x>, for all <x> and <y>.
2. +/-0.0 * <x> = +/-0.0, at least for all <x> that correspond to representable numbers (IEEE "not a number" and "infinity" encodings may be exceptions).
3. +1.0 * <x> = <x>, for all <x>.

Multiplication by zero and one should be invariant, as it may be used to evaluate conditional expressions without branching.

3.11.5.20 POW: Exponentiate

The POW instruction approximates the value of the first scalar operand raised to the power of the second scalar operand and replicates it to all four components of the result vector.

```
  tmp0 = ScalarLoad(op0);
  tmp1 = ScalarLoad(op1);
  result.x = ApproxPower(tmp0, tmp1);
  result.y = ApproxPower(tmp0, tmp1);
  result.z = ApproxPower(tmp0, tmp1);
  result.w = ApproxPower(tmp0, tmp1);
```

The exponentiation approximation function may be implemented using the base 2 exponentiation and logarithm approximation operations in the EX2 and LG2 instructions. In particular,

```
  ApproxPower(a,b) = ApproxExp2(b * ApproxLog2(a)).
```

Note that a logarithm may be involved even for cases where the exponent is an integer. This means that it may not be possible to exponentiate correctly with a negative base. In constrast, it is possible in a "normal" mathematical formulation to raise negative numbers to integral powers (e.g., (-3)^2== 9, and (-0.5)^-2==4).

3.11.5.21 RCP: Reciprocal

The RCP instruction approximates the reciprocal of the scalar operand and replicates it to all four components of the result vector.

```
  tmp = ScalarLoad(op0);
  result.x = ApproxReciprocal(tmp);
  result.y = ApproxReciprocal(tmp);
  result.z = ApproxReciprocal(tmp);
  result.w = ApproxReciprocal(tmp);
```

The following rule applies to reciprocation:

```
  1. ApproxReciprocal(+1.0) = +1.0.
```

3.11.5.22 RSQ: Reciprocal Square Root

The RSQ instruction approximates the reciprocal of the square root of the absolute value of the scalar operand and replicates it to all four components of the result vector.

```
  tmp = fabs(ScalarLoad(op0));
  result.x = ApproxRSQRT(tmp);
  result.y = ApproxRSQRT(tmp);
  result.z = ApproxRSQRT(tmp);
  result.w = ApproxRSQRT(tmp);
```

3.11.5.23 SCS: Sine/Cosine

The SCS instruction approximates the trigonometric sine and cosine of the angle specified by the scalar operand and places the cosine in the x component and the sine in the y component of the result vector. The z and w components of the result vector are undefined. The angle is specified in radians and must be in the range [-PI,PI].

```
  tmp = ScalarLoad(op0);
  result.x = ApproxCosine(tmp);
  result.y = ApproxSine(tmp);
```

If the scalar operand is not in the range [-PI,PI], the result vector is undefined.

3.11.5.24 SGE: Set On Greater or Equal Than

The SGE instruction performs a component-wise comparison of the two operands. Each component of the result vector is 1.0 if the corresponding component of the first operands is greater than or equal that of the second, and 0.0 otherwise.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = (tmp0.x >= tmp1.x) ? 1.0 : 0.0;
  result.y = (tmp0.y >= tmp1.y) ? 1.0 : 0.0;
  result.z = (tmp0.z >= tmp1.z) ? 1.0 : 0.0;
  result.w = (tmp0.w >= tmp1.w) ? 1.0 : 0.0;
```

3.11.5.25 SIN: Sine

The SIN instruction approximates the trigonometric sine of the angle specified by the scalar operand and replicates it to all four components of the result vector. The angle is specified in radians and does not have to be in the range [-PI,PI].

```
  tmp = ScalarLoad(op0);
  result.x = ApproxSine(tmp);
  result.y = ApproxSine(tmp);
  result.z = ApproxSine(tmp);
  result.w = ApproxSine(tmp);
```

3.11.5.26 SLT: Set On Less Than

The SLT instruction performs a component-wise comparison of the two operands. Each component of the result vector is 1.0 if the corresponding component of the first operand is less than that of the second, and 0.0 otherwise.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = (tmp0.x < tmp1.x) ? 1.0 : 0.0;
  result.y = (tmp0.y < tmp1.y) ? 1.0 : 0.0;
  result.z = (tmp0.z < tmp1.z) ? 1.0 : 0.0;
  result.w = (tmp0.w < tmp1.w) ? 1.0 : 0.0;
```

3.11.5.27 SUB: Subtract

The SUB instruction performs a component-wise subtraction of the second operand from the first to yield a result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = tmp0.x - tmp1.x;
  result.y = tmp0.y - tmp1.y;
  result.z = tmp0.z - tmp1.z;
  result.w = tmp0.w - tmp1.w;
```

3.11.5.28 SWZ: Extended Swizzle

The SWZ instruction loads the single vector operand, and performs a swizzle operation more powerful than that provided for loading normal vector operands to yield an instruction vector.

After the operand is loaded, the "x", "y", "z", and "w" components of the result vector are selected by the first, second, third, and fourth matches of the <xyzwExtSwizComp> or <rgbaExtSwizComp> pattern in the <extendedSwizzle> rule.

A result component can be selected from any of the four components of the operand or the constants 0.0 and 1.0. The result component can also be optionally negated. The following pseudocode describes the component selection method. "operand" refers to the vector operand. "select" is an enumerant where the values ZERO, ONE, X, Y, Z, and W correspond to the <xyzwExtSwizSel> rule matching "0", "1", "x", "y", "z", and "w", respectively, or the <rgbaExtSwizSel> rule matching "0", 1", "r", "g", "b", and "a", respectively. "negate" is TRUE if and only if the <optionalSign> rule in <xyzwExtSwizComp> or <rgbaExtSwizComp> matches "-".

```
float ExtSwizComponent(floatVec operand, enum select, boolean negate)
{
    float result;
    switch (select) {
      case ZERO:  result = 0.0; break;
      case ONE:   result = 1.0; break;
      case X:     result = operand.x; break;
      case Y:     result = operand.y; break;
      case Z:     result = operand.z; break;
      case W:     result = operand.w; break;
    }
    if (negate) {
      result = -result;
    }
    return result;
}
```

The entire extended swizzle operation is then defined using the following pseudocode:

```
tmp = VectorLoad(op0);
result.x = ExtSwizComponent(tmp, xSelect, xNegate);
result.y = ExtSwizComponent(tmp, ySelect, yNegate);
result.z = ExtSwizComponent(tmp, zSelect, zNegate);
result.w = ExtSwizComponent(tmp, wSelect, wNegate);
```

"xSelect", "xNegate", "ySelect", "yNegate", "zSelect", "zNegate", "wSelect", and "wNegate" correspond to the "select" and "negate" values above for the four <xyzwExtSwizComp> or <rgbaExtSwizComp> matches.

Since this instruction allows for component selection and negation for each individual component, the grammar does not allow the use of the normal swizzle and negation operations allowed for vector operands in other instructions.

3.11.5.29 XPD: Cross Product

The XPD instruction computes the cross product using the first three components of its two vector operands to generate the x, y, and z components of the result vector. The w component of the result vector is undefined.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = tmp0.y * tmp1.z - tmp0.z * tmp1.y;
  result.y = tmp0.z * tmp1.x - tmp0.x * tmp1.z;
  result.z = tmp0.x * tmp1.y - tmp0.y * tmp1.x;
```

3.11.6 Fragment Program Texture Instruction Set

The first three texture instructions described below specify the mapping of 4-tuple vectors to colors of an image. The sampling of the texture works as described in section 3.8, except that texture environments and texture functions are not applicable, and the texture enables hierarchy is replaced by explicit references to the desired texture target (i.e., 1D, 2D, 3D, cube map, rectangle). These texture instructions specify how the 4-tuple is mapped into the coordinates used for sampling. The following function is used to describe the texture sampling in the descriptions below:

```
  vec4 TextureSample(float s, float t, float r, float lodBias,
                     int texImageUnit, enum texTarget);
```

Note that not all three texture coordinates, s, t, and r, are used by all texture targets. In particular, 1D texture targets only use the s component, and 2D and rectangle (non-power-of-two) texture targets only use the s and t components. The descriptions of the texture instructions below supply all three components, as would be the case with 3D or cube map targets.

If a fragment program samples from a texture target on a texture image unit where the bound texture object is not complete, as defined in section 3.8.9, the result will be the vector (R, G, B, A) = (0, 0, 0, 1).

A fragment program will fail to load if it attempts to sample from multiple texture targets on the same texture image unit. For example, the following program would fail to load:

```
  !!ARBfp1.0
  TEX result.color, fragment.texcoord[0], texture[0], 2D;
  TEX result.depth, fragment.texcoord[1], texture[0], 3D;
  END
```

The fourth texture instruction described below, KIL, does not sample from a texture, but rather prevents further processing of the current fragment if any component of its 4-tuple vector is less than zero.

A dependent texture instruction is one that samples using a texture coordinate residing in a temporary, rather than in an attribute or a parameter. A program may have a chain of dependent texture instructions, where the result of the first texture instruction is used as the coordinate for a second texture instruction, which is in turn used as the coordinate for a third texture instruction, and so on. Each node in this chain is termed an indirection, and can be thought of as a set of texture samples that execute in parallel followed by a sequence of ALU instructions.

Some implementations may have limitations on how long the dependency chain may be, and so indirections are counted as a resource just like instructions or temporaries are counted. All programs have at least one indirection, or one node in this chain, even if the program performs no texture operation. Each instruction encountered is included in this node until a texture instruction is encountered

- whose texture coordinate is a temporary that has been previously written in the current node; or

- whose result vector is a temporary that is also the operand or result vector of a previous ALU instruction in the current node.

A new node is then started, including the texture instruction and all subsequent instructions, and the process repeats for all instructions in the program. Note that for simplicity in counting, result writemasks and operand suffixes are not taken into consideration when counting indirections.

3.11.6.1 TEX: Map coordinate to color

The TEX instruction takes the first three components of its source vector, and maps them to s, t, and r. These coordinates are used to sample from the specified texture target on the specified texture image unit in a manner consistent with its parameters. The resulting sample is mapped to RGBA as described in table 3.21 and written to the result vector.

```
  tmp = VectorLoad(op0);
  result = TextureSample(tmp.x, tmp.y, tmp.z, 0.0, op1, op2);
```

3.11.6.2 TXP: Project coordinate and map to color

The TXP instruction divides the first three components of its source vector by the fourth component and maps the results to s, t, and r. These coordinates are used to sample from the specified texture target on the specified texture image unit in a manner consistent with its parameters. The resulting sample is mapped to RGBA as described in table 3.21 and written to the result vector. If the value of the fourth component of the source vector is less than or equal to zero, the result vector is undefined.

```
  tmp = VectorLoad(op0);
  tmp.x = tmp.x / tmp.w;
  tmp.y = tmp.y / tmp.w;
  tmp.z = tmp.z / tmp.w;
  result = TextureSample(tmp.x, tmp.y, tmp.z, 0.0, op1, op2);
```

3.11.6.3 TXB: Map coordinate to color while biasing its LOD

The TXB instruction takes the first three components of its source vector and maps them to s, t, and r. These coordinates are used to sample from the specified texture target on the specified texture image unit in a manner consistent with its parameters. Additionally, the fourth component of the source vector is applied to equation 3.14 as fragment_bias below to further bias the level of detail.

```
 lambda'(x,y) = log2[p(x,y)] +
                clamp(texobj_bias + texunit_bias + fragment_bias)
```

The resulting sample is mapped to RGBA as described in table 3.21 and written to the result vector.

```
  tmp = VectorLoad(op0);
  result = TextureSample(tmp.x, tmp.y, tmp.z, tmp.w, op1, op2);
```

3.11.6.4 KIL: Kill fragment

Rather than mapping a coordinate set to a color, this function prevents a fragment from receiving any future processing. If any component of its source vector is negative, the processing of this fragment will be discontinued and no further outputs to this fragment will occur. Subsequent stages of the GL pipeline will be skipped for this fragment.

```
  tmp = VectorLoad(op0);
  if ((tmp.x < 0) || (tmp.y < 0) ||
      (tmp.z < 0) || (tmp.w < 0))
  {
      exit;
  }
```

3.11.7 Program Matrices

In addition to GL's conventional matrices, several additional program matrices are available for use as program parameters. These matrices have names of the form MATRIX<i>_ARB where <i> is between zero and <n>-1 where <n> is the value of the implementation-dependent constant MAX_PROGRAM_MATRICES_ARB. The MATRIX<i>_ARB constants obey MATRIX<i>_ARB = MATRIX0_ARB + <i>. The value of MAX_PROGRAM_MATRICES_ARB must be at least eight. The maximum stack depth for program matrices is defined by the MAX_PROGRAM_MATRIX_STACK_DEPTH_ARB and must be at least 1.

3.11.8 Required Fragment Program State

The state required to support program objects of all targets consists of:

  an integer for the program error position, initially -1;

  an array of ubytes for the program error string, initially empty;

and the state that must be maintained to indicate which integers are currently in use as program object names.

The state required to support the fragment program target consists of:

a bit indicating whether or not fragment program mode is enabled, initially disabled;

a set of MAX_PROGRAM_ENV_PARAMETERS_ARB four-component floating-point program environment parameters, initially set to (0,0,0,0);

an unsigned integer naming the currently bound fragment program, initially zero;

The state required for each fragment program object consists of:

an unsigned integer indicating the program object name;

an array of type ubyte containing the program string, initially empty;

an unsigned integer holding the length of the program string, initially zero;

an enum indicating the program string format, initially PROGRAM_FORMAT_ASCII_ARB;

a bit indicating whether or not the program exceeds the native limits;

six unsigned integers holding the number of instruction (ALU, texture, and total), texture indirection, temporary variable, and program parameter binding resources used by the program, initially all zero;

six unsigned integers holding the number of native instruction (ALU, texture, and total), texture indirection, temporary variable, and program parameter binding resources used by the program, initially all zero;

and a set of MAX_PROGRAM_LOCAL_PARAMETERS_ARB four-component floating-point program local parameters, initially set to (0,0,0,0).

Initially, no fragment program objects exist.

Additions to Chapter 4 of the OpenGL 1.3 Specification (Per-Fragment Operations and the Frame Buffer)

None

Additions to Chapter 5 of the OpenGL 1.3 Specification (Special Functions)

Modify Section 5.4, Display Lists (p. 191)

(modify third paragraph, p. 195) ... These are IsList, GenLists, ..., IsProgramARB, GenProgramsARB, and DeleteProgramsARB, as well as IsEnabled and all the Get commands (chapter 6).

Additions to Chapter 6 of the OpenGL 1.3 Specification (State and State Requests)

Modify Section 6.1.2, Data Conversions (p. 198)

(add before last paragraph, p. 198) The matrix selected by the current matrix mode can be queried by calling GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev with <pname> set to CURRENT_MATRIX_ARB; the matrix will be returned in transposed form with <pname> set to TRANSPOSE_CURRENT_MATRIX_ARB. The depth of the selected matrix stack can be queried with <pname> set to CURRENT_MATRIX_STACK_DEPTH_ARB. Querying CURRENT_MATRIX_ARB and CURRENT_MATRIX_STACK_DEPTH_ARB is the only means for querying the matrix and matrix stack depth of the program matrices described in section 3.11.7.

(add to end of last paragraph, p. 199) Queries of texture state variables corresponding to texture coordinate processing unit (namely, TexGen state and enables, and matrices) will produce an INVALID_OPERATION error if the value of ACTIVE_TEXTURE is greater than or equal to MAX_TEXTURE_COORDS_ARB. All other texture state queries will result in an INVALID_OPERATION error if the value of ACTIVE_TEXTURE is greater than or equal to MAX_TEXTURE_IMAGE_UNITS_ARB.

Modify Section 6.1.11, Pointer and String Queries (p. 206)

(modify last paragraph, p. 206) ... The possible values for <name> are VENDOR, RENDERER, VERSION, EXTENSIONS, and PROGRAM_ERROR_STRING_ARB.

(add after last paragraph of section, p. 207) Queries of PROGRAM_ERROR_STRING_ARB return a pointer to an implementation-dependent program load error string. If the last call to ProgramStringARB failed to load a program, the returned string describes at least one reason why the program failed to load. If the last call to ProgramStringARB successfully loaded a program, the returned string may be empty (containing only a zero terminator) or may contain one or more implementation-dependent warning messages. The contents of the error string are guaranteed to remain constant only until the next ProgramStringARB command, which may overwrite the error string.

Insert a new Section 6.1.12, Program Queries (p. 207), between existing sections 6.1.11 and 6.1.12.

6.1.12 Program Queries

The commands

```
  void GetProgramEnvParameterdvARB(enum target, uint index,
                                   double *params);
  void GetProgramEnvParameterfvARB(enum target, uint index,
                                   float *params);
```

obtain the current value for the program environment parameter numbered <index> for the given program target <target>, and places the information in the array <params>. The error INVALID_ENUM is generated if <target> specifies a nonexistent program target or a program target that does not support program environment parameters. The error INVALID_VALUE is generated if <index> is greater than or equal to the implementation-dependent number of supported program environment parameters for the program target.

When <target> is FRAGMENT_PROGRAM_ARB, each program parameter returned is an array of four values.

The commands

```
  void GetProgramLocalParameterdvARB(enum target, uint index,
                                     double *params);
  void GetProgramLocalParameterfvARB(enum target, uint index,
                                     float *params);
```

obtain the current value for the program local parameter numbered <index> belonging to the program object currently bound to <target>, and places the information in the array <params>. The error INVALID_ENUM is generated if <target> specifies a nonexistent program target or a program target that does not support program local parameters. The error INVALID_VALUE is generated if <index> is greater than or equal to the implementation-dependent number of supported program local parameters for the program target.

When the program target type is FRAGMENT_PROGRAM_ARB, each program local parameter returned is an array of four values.

The command

```
  void GetProgramivARB(enum target, enum pname, int *params);
```

obtains program state for the program target <target>, writing the state into the array given by <params>. GetProgramivARB can be used to determine the properties of the currently bound program object or implementation limits for <target>.

If <pname> is PROGRAM_LENGTH_ARB, PROGRAM_FORMAT_ARB, or PROGRAM_BINDING_ARB, GetProgramivARB returns one integer holding the program string length (in bytes), program string format, and program name, respectively, for the program object currently bound to <target>.

If <pname> is MAX_PROGRAM_LOCAL_PARAMETERS_ARB or MAX_PROGRAM_ENV_PARAMETERS_ARB, GetProgramivARB returns one integer holding the maximum number of program local parameters or program environment parameters, respectively, supported for the program target <target>.

If <pname> is MAX_PROGRAM_INSTRUCTIONS_ARB, MAX_PROGRAM_ALU_INSTRUCTIONS_ARB, MAX_PROGRAM_TEX_INSTRUCTIONS_ARB, MAX_PROGRAM_TEX_INDIRECTIONS_ARB, MAX_PROGRAM_TEMPORARIES_ARB, MAX_PROGRAM_PARAMETERS_ARB, or MAX_PROGRAM_ATTRIBS_ARB, GetProgramivARB returns a single integer giving the maximum number of total instructions, ALU instructions, texture instructions, texture indirections, temporaries, parameters, and attributes that can be used by a program of type <target>. If <pname> is PROGRAM_INSTRUCTIONS_ARB, PROGRAM_ALU_INSTRUCTIONS_ARB, PROGRAM_TEX_INSTRUCTIONS_ARB, PROGRAM_TEX_INDIRECTIONS_ARB, PROGRAM_TEMPORARIES_ARB, PROGRAM_PARAMETERS_ARB, or PROGRAM_ATTRIBS_ARB, GetProgramivARB returns a single integer giving the number of total instructions, ALU instructions, texture instructions, texture indirections, temporaries, parameters, and attributes used by the current program for <target>.

If <pname> is MAX_PROGRAM_NATIVE_INSTRUCTIONS_ARB, MAX_PROGRAM_NATIVE_ALU_INSTRUCTIONS_ARB, MAX_PROGRAM_NATIVE_TEX_INSTRUCTIONS_ARB, MAX_PROGRAM_NATIVE_TEX_INDIRECTIONS_ARB, MAX_PROGRAM_NATIVE_TEMPORARIES_ARB, MAX_PROGRAM_NATIVE_PARAMETERS_ARB, or MAX_PROGRAM_NATIVE_ATTRIBS_ARB, GetProgramivARB returns a single integer giving the maximum number of native instruction, ALU instruction, texture instruction, texture indirection, temporary, parameter, and attribute resources available to a program of type <target>. If <pname> is PROGRAM_NATIVE_INSTRUCTIONS_ARB, PROGRAM_NATIVE_ALU_INSTRUCTIONS_ARB, PROGRAM_NATIVE_TEX_INSTRUCTIONS_ARB, PROGRAM_NATIVE_TEX_INDIRECTIONS_ARB, PROGRAM_NATIVE_TEMPORARIES_ARB, PROGRAM_NATIVE_PARAMETERS_ARB, or PROGRAM_NATIVE_ATTRIBS_ARB, GetProgramivARB returns a single integer giving the number of native instruction, ALU instruction, texture instruction, texture indirection, temporary, parameter, and attribute resources consumed by the program currently bound to <target>. Native resource counts will reflect the results of implementation-dependent scheduling and optimization algorithms applied by the GL, as well as emulation of non-native features. If <pname> is PROGRAM_UNDER_NATIVE_LIMITS_ARB, GetProgramivARB returns 0 if the native resource consumption of the program currently bound to <target> exceeds the number of available resources for any resource type, and 1 otherwise.

The command

```
  void GetProgramStringARB(enum target, enum pname, void *string);
```

obtains the program string for the program object bound to <target> and places the information in the array <string>. <pname> must be PROGRAM_STRING_ARB. <n> ubytes are returned into the array program where <n> is the length of the program in ubytes, as returned by GetProgramivARB when <pname> is PROGRAM_LENGTH_ARB. The program string is always returned using the format given when the program string was specified.

The command

```
boolean IsProgramARB(uint program);
```

returns TRUE if <program> is the name of a program object. If <program> is zero or is a non-zero value that is not the name of a program object, or if an error condition occurs, IsProgramARB returns FALSE. A name returned by GenProgramsARB, but not yet bound, is not the name of a program object.

Modify Section 6.2, State Tables (p. 216)

(add to caption of Table 6.5) When accessing the current texture coordinates (CURRENT_TEXTURE_COORDS) or the texture coordinates associated with raster position (CURRENT_RASTER_TEXTURE_COORDS), the active texture unit selector (ACTIVE_TEXTURE) must be less than the implementation dependent maximum number of texture coordinate sets (MAX_TEXTURE_COORDS_ARB).

(add to caption of Table 6.8) When accessing the texture matrix stack (TEXTURE_MATRIX, TRANSPOSE_TEXTURE_MATRIX) or the texture matrix stack pointer (TEXTURE_STACK_DEPTH), the active texture unit selector (ACTIVE_TEXTURE) must be less than the implementation dependent maximum number of texture coordinate sets (MAX_TEXTURE_COORDS_ARB).

(split Table 6.17 into two tables, Texture Environment and Texture Coordinate Generation; move active texture unit selector and texture coordinate generation state to table 6.18; renumber subsequent tables)

(add to captions of Tables 6.14, 6.15, 6.16) The active texture unit selector (ACTIVE_TEXTURE) identifies which texture object is accessed, and must be less than the implementation dependent maximum number of texture image units (MAX_TEXTURE_IMAGE_UNITS_ARB).

(add to caption of Table 6.18) With the exception of ACTIVE_TEXTURE, the active texture unit selector (ACTIVE_TEXTURE) identifies which texture coordinate set is accessed, and must be less than the implementation dependent maximum number of texture coordinate sets (MAX_TEXTURE_COORDS_ARB).

Additions to Appendix A of the OpenGL 1.3 Specification (Invariance)

Add to end of Section A.3 (p. 242):

Rule 4. Fragment program instructions not relevant to the calculation of any result must have no effect on that result.

Rule 5. Fragment program instructions relevant to the calculation of any result must always produce the identical result.

Instructions relevant to the calculation of a result are any instructions in a sequence of instructions that eventually determine the source values for the calculation under consideration.

There is no guaranteed invariance between fragment colors generated by conventional GL texturing mode and fragment colors generated by fragment program mode. Multi-pass rendering algorithms that require rendering invariances to operate correctly should not mix conventional GL fragment texturing mode with fragment program mode for different rendering passes. However, such algorithms will operate correctly if the algorithms limit themselves to a single mode of fragment color generation.

There is no guaranteed invariance between the final z window coordinates of fragments processed by fragment programs that write depth values and fragments processed by any other means, even if the fragment programs in question simply copy the z value from the "fragment.position" binding. Multi-pass rendering algorithms that use depth-replacing fragment programs should use depth-replacing fragment programs on each pass to guarantee identical z values.

The texture sample chosen for a fragment of a primitive must be invariant between fragment program mode and conventional texture application mode subject to these conditions:

1. All state with the exception of fragment program state is identical

2. The primitives generating the fragments are identical

3. The sample in the fragment program mode is the result of a 'TEX' instruction (or a 'TXP' instruction with a unity q)

4. The texture coordinate operand for the texture instruction uses the same texture coordinate set as the conventional mode sample

5. The texture coordinate operand for the texture instruction has not been the result of any other operations in the fragment program

Additions to the AGL/GLX/WGL Specifications

Program objects are shared between AGL/GLX/WGL rendering contexts if and only if the rendering contexts share display lists. No change is made to the AGL/GLX/WGL API.

Changes to program objects shared between multiple rendering contexts will be serialized (i.e., the changes will occur in a specific order).

Changes to a program object made by one rendering context are not guaranteed to take effect in another rendering context until the other calls BindProgram to bind the program object.

When a program object is deleted by one rendering context, the object itself is not destroyed until it is no longer the current program object in any context. However, the name of the deleted object is removed from the program object name space, so the next attempt to bind a program using the same name will create a new program object. Recall that destroying a program object bound in

    the current rendering context effectively unbinds the object being
    destroyed.

Dependencies on OpenGL 1.4

    If OpenGL 1.4 is not supported, the modified equation for the
    calculation of level of detail by the TXB instruction in 3.11.6.3
    should read

```
      lambda'(x,y) = log2[p(x,y)] +
                     clamp(texunit_bias + fragment_bias)
```

Dependencies on EXT_vertex_weighting and ARB_vertex_blend

    If EXT_vertex_weighting and ARB_vertex_blend are both not supported,
    all discussions of multiple modelview matrices should be removed.

    In particular, the line in the grammar

```
      <stateMatrixName>      ::= "modelview" <stateOptModMatNum>
```

    should be changed to

```
      <stateMatrixName>      ::= "modelview"
```

    and the rules <stateOptModMatNum> and <stateModMatNum> should be
    deleted. The first line of Table X.2.7 should be modified to read:

```
      Binding                                Underlying State
      ------------------------------------   --------------------------
        state.matrix.modelview               modelview matrix
```

    The caption for Table X.2.7 should be modified to exclude optional
    modelview matrix number. Subsequent references to "modelview matrix
    zero" and "modelview matrix 1" should be changed to "modelview
    matrix" and the example "state.matrix.modelview[1].row[0]" should be
    changed to "state.matrix.modelview.row[0]".

Dependencies on ARB_matrix_palette:

    If ARB_matrix_palette is not supported, all discussions of the
    matrix palette should be removed.

    In particular, the line

```
      "palette" "[" <statePaletteMatNum> "]"
```

    should be removed from the <stateMatrixName> grammar rule, and the
    <statePaletteMatNum> grammar rule should be removed entirely.
    "state.matrix.palette[n]" should be removed from Table X.2.7.

Dependencies on ARB_transpose_matrix

    If ARB_transpose_matrix is not supported, the discussion of
    TRANSPOSE_CURRENT_MATRIX_ARB in the edits to section 6.1.2 should be
    removed.

Dependencies on EXT_fog_coord

```
    If EXT_fog_coord is not supported, references to "fog coordinate"
    in the definition of the "fragment.fogcoord" attribute should be
    removed.
```

Dependencies on NV_texture_rectangle

```
    If NV_texture_rectangle is not supported, the discussion of the
    rectangle (non-power-of-two) texture target in section 3.11.6 should
    be removed, and the line

      "RECT"

    should be removed from the <texTarget> grammar rule.
```

Interactions with ARB_shadow

```
    The texture comparison introduced by ARB_shadow can be expressed in
    terms of a fragment program, and in fact use the same internal
    resources on some implementations.  Therefore, if fragment program
    mode is enabled, the GL behaves as if TEXTURE_COMPARE_MODE_ARB is
    NONE.
```

Interactions with ARB_vertex_program

```
    The program object management entrypoints described in sections
    2.14.1 (for vertex programs) and 3.11.1 (for fragment programs)
    are shared by both program targets.  The PROGRAM_ERROR_STRING_ARB
    and program queries in sections 6.1.11 and 6.1.12 are also shared,
    as are all common tokens.

    The Errors section should be modified to generate INVALID_OPERATION
    from the Get command with argument CURRENT_MATRIX_ARB,
    TRANSPOSE_CURRENT_MATRIX_ARB, and CURRENT_MATRIX_STACK_DEPTH_ARB
    when the current matrix mode is TEXTURE.

    In the presence of ARB_vertex_program, ARB_fragment_program must
    recognize and return appropriate values for the GetProgram <pname>
    tokens introduced in that spec but not otherwise shared by
    ARB_fragment_program:

        PROGRAM_ADDRESS_REGISTERS_ARB                   0x88B0
        MAX_PROGRAM_ADDRESS_REGISTERS_ARB               0x88B1
        PROGRAM_NATIVE_ADDRESS_REGISTERS_ARB            0x88B2
        MAX_PROGRAM_NATIVE_ADDRESS_REGISTERS_ARB        0x88B3
```

The following tables list new program object state and implementation-dependent state:

Get Value	Type	Get Command	Initial Value	Description	Sec	Attrib
PROGRAM_ADDRESS_REGISTERS_ARB	Z+	GetProgramivARB	0	bound program address registers	6.1.12	-
PROGRAM_NATIVE_ADDRESS_ REGISTERS_ARB	Z+	GetProgramivARB	0	bound program native address registers	6.1.12	-

Table X.7. Program Object State. Program object queries return attributes of the program object currently bound to the program target <target>.

Get Value	Type	Get Command	Minimum Value	Description	Sec.	Attrib
MAX_PROGRAM_ADDRESS_REGISTERS_ARB	Z+	GetProgramivARB	0	maximum program address registers	6.1.12	-
MAX_PROGRAM_NATIVE_ADDRESS_ REGISTERS_ARB	Z+	GetProgramivARB	0	maximum program native address registers	6.1.12	-

Table X.10. New Implementation-Dependent Values Introduced by ARB_vertex_program.

In the presence of ARB_fragment_program, ARB_vertex_program must recognize and return appropriate values for the GetProgram <pname> tokens introduced in this spec. The following tables list new program object state and implementation-dependent state:

Get Value	Type	Get Command	Initial Value	Description	Sec	Attrib
PROGRAM_ALU_INSTRUCTIONS_ARB	Z+	GetProgramivARB	0	maximum program ALU instructions	6.1.12	-
PROGRAM_TEX_INSTRUCTIONS_ARB	Z+	GetProgramivARB	0	maximum program texture instructions	6.1.12	-
PROGRAM_TEX_INDIRECTIONS_ARB	Z+	GetProgramivARB	0	maximum program texture indirections	6.1.12	-
PROGRAM_NATIVE_ALU_INSTRUCTIONS_ARB	Z+	GetProgramivARB	0	maximum program native ALU instructions	6.1.12	-
PROGRAM_NATIVE_TEX_INSTRUCTIONS_ARB	Z+	GetProgramivARB	0	maximum program native texture instructions	6.1.12	-
PROGRAM_NATIVE_TEX_INDIRECTIONS_ARB	Z+	GetProgramivARB	0	maximum program native texture indirections	6.1.12	-

Table X.7. Program Object State. Program object queries return attributes of the program object currently bound to the program target <target>.

Get Value	Type	Get Command	Minimum Value	Description	Sec.	Attrib
MAX_PROGRAM_ALU_INSTRUCTIONS_ARB	Z+	GetProgramivARB	0	Number of frag. prg. ALU instructions	6.1.12	-
MAX_PROGRAM_TEX_INSTRUCTIONS_ARB	Z+	GetProgramivARB	0	Number of frag. prg. texture instructions	6.1.12	-
MAX_PROGRAM_TEX_INDIRECTIONS_ARB	Z+	GetProgramivARB	0	Number of frag. prg. texture indirections	6.1.12	-
MAX_PROGRAM_NATIVE_ALU_INSTRUCTIONS_ARB	Z+	GetProgramivARB	0	maximum program native ALU instructions	6.1.12	-
MAX_PROGRAM_NATIVE_TEX_INSTRUCTIONS_ARB	Z+	GetProgramivARB	0	maximum program native texture instructions	6.1.12	-
MAX_PROGRAM_NATIVE_TEX_INDIRECTIONS_ARB	Z+	GetProgramivARB	0	maximum program native texture indirections	6.1.12	-

Table X.10. New Implementation-Dependent Values Introduced by ARB_fragment_program.

Interactions with ATI_fragment_shader

The existing ATI_fragment_shader extension, if supported, also provides a similar fragment programming model. Mixing the two models in a single application is possible but not recommended. FRAGMENT_PROGRAM_ARB has priority over FRAGMENT_SHADER_ATI if both are enabled.

Interactions with NV_fragment_program

The NV_fragment_program extension, if supported, also provides a similar programming model. This extension is incompatible with NV_fragment_program in a number of different ways. Mixing the two models in a single application is possible but not recommended. The interactions between the extensions are defined below.

Functions, enumerants, and programs defined in NV_fragment_program are called "NV functions", "NV enumerants", and "NV programs," respectively. Functions, enumerants, and programs defined in ARB_fragment_program are called "ARB functions", "ARB enumerants", and "ARB programs," respectively.

The following GL state is identical in the two extensions:

- Fragment program mode enable. The NV and ARB enumerants have different values, but the same effect.

- Program error position.

- Program error string.

- NV_fragment_program and ARB_fragment_program "program local parameters."

- Fragment program names, targets, formats, program string, program string lengths, and residency information. The ARB and NV query functions operate differently. The ARB query function does not allow queries of target (passed in to the query) and residency information. The NV query function does not allow queries of program name (passed in to the query) or format. The format of NV programs is always PROGRAM_FORMAT_ASCII_ARB.

- Program object name space. Program objects are created differently in the NV and ARB specs. Under the NV spec, program objects are created by calling LoadProgramNV. Under the ARB spec, program objects are created by calling BindProgramARB with an unused program name.

The following state is provided only by ARB_fragment_program:

- Program environment parameters.

- Implementation-dependent limits on the number of instructions, ALU instructions, texture instructions, texture indirections, program parameters, fragment attributes, resource counts, and native resource counts. The instruction limit is baked into the NV spec. Implementations supporting NV_fragment_program have no specific restrictions on the number of ALU instructions, texture instructions, texture indirections, or fragment attributes used. Such implementations also have no limit on program parameters used, except that no more than one may be used by any single program instruction.

The following state is provided only by NV_fragment_program:

- Named program parameters (variables defined in the program text and updated by name).

The following are additional functional differences between ARB_fragment_program and NV_fragment_program:

- NV programs use a set of register names, with no support for user-defined variables (other than parameters in the program). ARB programs provide no support for fixed variable names; all variables must be declared, explicitly or implicitly, in the program.

- ARB programs support parameter variables that can be bound to selected GL state variables, and are updated automatically when the underlying state changes. NV programs provide no such support; applications must set program parameters themselves.

- ARB_fragment_program doesn't provide explicit support for multiple data types (fx12, fp16, fp32) described in NV_fragment_program, and provides no mechanism for controlling the precision used to carry out arithmetic operations.

- ARB_fragment_program doesn't support condition codes, conditional writemasks, or the "C" instruction suffix that specifies a condition code update.

- ARB_fragment_program doesn't support an absolute value operator that can be applied to a source vector as it is loaded.

- ARB_fragment_program doesn't define behavior for many floating-point special cases. On platforms where NV_fragment_program is supported, ARB programs will have the same special-case behavior.

```
    - Language to declare program parameters is slightly different
      (NV_fragment_program has "DECLARE" and "DEFINE";
      ARB_fragment_program has "PARAM").

    - NV_fragment_program provides a number of instructions not found
      in ARB_fragment_program:

        * DDX, DDY:  partial derivatives relative to x and  y.

        * "PK*" and "UP*":  packing and unpacking instructions.

        * RFL:  reflection vector.

        * SEQ, SFL, SGT, SLE, SNE, STR:  set on equal, false, greater
          than, less than or equal, not equal, and true, respectively.

        * TXD:  texture lookup w/partials.

        * X2D:  2D coordinate transformation.

    - ARB_fragment_program provides several instructions not found in
      NV_fragment_program, and there are a few instruction set
      differences:

        * ABS:  absolute value.  ABS instructions are unnecessary in
            NV_fragment_program because of the free absolute value on
            input operator.  Equivalent to:

               MOV dst, |src|;

        * CMP:  compare.  Roughly equivalent to the following
            sequence, but may be optimized further:

               SLT tmp, src0;
               LRP dst, tmp, src1, src2;

        * DPH:  homogenous dot product.  Equivalent to:

               DP3 tmp, src0, src1;
               ADD dst, tmp, src0.w;

        * KIL:  kill fragment.  Both extensions support this
            instruction, but the ARB instruction takes a vector
            operand rather than a condition code.

        * SCS:  sine/cosine.  Emulated using the separate SIN and COS
            instructions in NV_fragment_program, which also have no
            restriction on the input values.

        * SWZ:  extended swizzle.  On NV_fragment_program platforms,
            this instruction will be emulated using a single MAD
            instruction and a program parameter constant.

        * TXB:  texture sample with bias.  Not exposed in the
            NV_fragment_program API.
        * XPD:  cross product.  Emulated using a MUL and a MAD
            instruction.
```

GLX Protocol

```
    The following rendering commands are sent to the server as part of
    a glXRender request:

        BindProgramARB
            2           12              rendering command length
            2           4180            rendering command opcode
            4           ENUM            target
            4           CARD32          program

        ProgramEnvParameter4fvARB
            2           32              rendering command length
            2           4184            rendering command opcode
            4           ENUM            target
            4           CARD32          index
            4           FLOAT32         params[0]
            4           FLOAT32         params[1]
            4           FLOAT32         params[2]
            4           FLOAT32         params[3]

        ProgramEnvParameter4dvARB
            2           44              rendering command length
            2           4185            rendering command opcode
            4           ENUM            target
            4           CARD32          index
            8           FLOAT64         params[0]
            8           FLOAT64         params[1]
            8           FLOAT64         params[2]
            8           FLOAT64         params[3]

        ProgramLocalParameter4fvARB
            2           32              rendering command length
            2           4215            rendering command opcode
            4           ENUM            target
            4           CARD32          index
            4           FLOAT32         params[0]
            4           FLOAT32         params[1]
            4           FLOAT32         params[2]
            4           FLOAT32         params[3]

        ProgramLocalParameter4dvARB
            2           44              rendering command length
            2           4216            rendering command opcode
            4           ENUM            target
            4           CARD32          index
            8           FLOAT64         params[0]
            8           FLOAT64         params[1]
            8           FLOAT64         params[2]
            8           FLOAT64         params[3]

    The ProgramStringARB is potentially large, and hence can be sent in
    a glXRender or glXRenderLarge request.
    **ProgramStringARB**
        2           16+len+p        rendering command length
        2           4217            rendering command opcode
        4           ENUM            target
        4           ENUM            format
        4           sizei           len
        len         LISTofBYTE      program
        p                           unused, p=pad(len)

     If the command is encoded in a glxRenderLarge request, the
     command opcode and command length fields above are expanded to
     4 bytes each:

        4           16+len+p        rendering command length
        4           4217            rendering command opcode

The remaining commands are non-rendering commands.  These commands
are sent separately (i.e., not as part of a glXRender or
glXRenderLarge request), using the glXVendorPrivateWithReply
request:

    **DeleteProgramsARB**

            2           CARD16          sequence number
            4           0               reply length
            4           BOOL32          return value
            20                          unused
```

Errors

The error INVALID_OPERATION is generated by ProgramStringARB if the program string <string> is syntactically incorrect or violates any semantic restriction of the execution environment of the specified program target <target>. The error INVALID_OPERATION may also be generated by ProgramStringARB if the specified program would exceed native resource limits of the implementation.

The error INVALID_OPERATION is generated by BindProgramARB if <program> is the name of a program whose target does not match <target>.

The error INVALID_VALUE is generated by commands ProgramEnvParameter{fd}ARB, ProgramEnvParameter{fd}vARB, and GetProgramEnvParameter{fd}vARB if <index> is greater than or equal to the value of MAX_PROGRAM_ENV_PARAMETERS_ARB corresponding to the program target <target>.

The error INVALID_VALUE is generated by commands ProgramLocalParameter4{fd}ARB, ProgramLocalParameter4{fd}vARB, and GetProgramLocalParameter{fd}vARB if <index> is greater than or equal to the value of MAX_PROGRAM_LOCAL_PARAMETERS_ARB corresponding to the program target <target>.

The error INVALID_OPERATION is generated if Begin, RasterPos, or any command that performs an explicit Begin is called when fragment program mode is enabled and the currently bound fragment program object does not contain a valid fragment program.

The error INVALID_OPERATION is generated by any command accessing texture coordinate processing state if the texture unit number corresponding to the current value of ACTIVE_TEXTURE is greater than or equal to the implementation-dependent constant MAX_TEXTURE_COORDS_ARB. Such commands include: GetTexGen{if}v; TexGen{ifd}, TexGen{ifd}v; Disable, Enable, IsEnabled with argument TEXTURE_GEN_{STRQ}; Get with argument CURRENT_TEXTURE_COORDS, CURRENT_RASTER_TEXTURE_COORDS, TEXTURE_STACK_DEPTH, TEXTURE_MATRIX, TRANSPOSE_TEXTURE_MATRIX; when the current matrix mode is TEXTURE, Frustum, LoadIdentity, LoadMatrix{fd}, LoadTransposeMatrix{fd}, MultMatrix{fd}, MultTransposeMatrix{fd}, Ortho, PopMatrix, PushMatrix, Rotate{fd}, Scale{fd}, Translate{fd}.

    The error INVALID_OPERATION is generated by any command accessing
    texture image processing state if the texture unit number
    corresponding to the current value of ACTIVE_TEXTURE is greater than
    or equal to the implementation-dependent constant
    MAX_TEXTURE_IMAGE_UNITS_ARB. Such commands include: BindTexture;
    GetCompressedTexImage, GetTexEnv{if}v, GetTexImage,
    GetTexLevelParameter{if}v, GetTexParameter{if}v; TexEnv{if},
    TexEnv{if}v, TexParameter{if}, TexParameter{if}v; Disable, Enable,
    IsEnabled with argument TEXTURE_{123}D, TEXTURE_CUBE_MAP; Get with
    argument TEXTURE_BINDING_{123}D, TEXTURE_BINDING_CUBE_MAP;
    CompressedTexImage{123}D, CompressedTexSubImage{123}D,
    CopyTexImage{12}D, CopyTexSubImage{123}D, TexImage{123}D,
    TexSubImage{123}D.

Sample Usage

The following program shows how to perform a simple modulation between the interpolated color and a single texture:

```
!!ARBfp1.0
# Simple program to show how to code up the default texture environment
ATTRIB tex = fragment.texcoord;      #first set of texture coordinates
ATTRIB col = fragment.color.primary; #diffuse interpolated color
OUTPUT outColor = result.color;
TEMP tmp;
TXP tmp, tex, texture, 2D;           #sample the texture
MUL outColor, tmp, col;              #perform the modulation
END
```

The following is an example the simulates a chrome surface:

```
  !!ARBfp1.0
  ########################
  # Input Textures:
  #-----------------------
  # Texture 0 contains the default 2D texture used for general mapping
  # Texture 2 contains a 1D pointlight falloff map
  # Texture 3 contains a 2D map for calculating specular lighting
  # Texture 4 contains normalizer cube map
  # Input Texture Coordinates:
  #-----------------------
  # TexCoord1 contains the calculated normal
  # TexCoord2 contains the light to vertex vector
  # TexCoord3 contains the half-vector in tangent space
  # TexCoord4 contains the light vector in tangent space
  # TexCoord5 contains the eye vector in tangent space
  ########################
  TEMP     NdotH, lV, L;
  ALIAS    diffuse  = L;
  PARAM       half  = { 0.5, 0.5, 0.5, 0.5 };
  ATTRIB   norm_tc  = fragment.texcoord[1];
  ATTRIB     lv_tc  = fragment.texcoord[2];
  ATTRIB   half_tc  = fragment.texcoord[3];
  ATTRIB  light_tc  = fragment.texcoord[4];
  ATTRIB    eye_tc  = fragment.texcoord[5];
  OUTPUT      oCol  = result.color;
  TEX     L, light_tc, texture[4], CUBE; # Sample cube map normalizer
  # Calculate diffuse lighting (N.L)
  SUB     L, L, half;             # Bias L and then multiply by 2
  ADD     L, L, L;
  DP3     diffuse, norm_tc, L;     # N.L
  # Calculate specular lighting component { (N.H), |H|^2 }
  DP3     NdotH.x, norm_tc, half_tc;
  DP3     NdotH.y, half_tc, half_tc;
  DP3     lV.x, lv_tc, lv_tc;     # lV = (|light to vertex|)^2
  #############
  # Pass 2
  #############
  TEMP     base, specular;
  ALIAS    atten  = lV;
  TEX base, eye_tc, texture[0], 2D; # sample enviroment map using eye vector
  TEX atten,    lV,     texture[2], 1D; # Sample attenuation map
  TEX specular, NdotH,  texture[3], 2D; # Sample specular NHHH map=(N.H)^256
  # specular = (N.H)^256 * (N.L)
  # this ensures a pixel is only lit if facing the light (since the specular
  # exponent makes negative N.H positive we must do this)
  MUL      specular, specular, diffuse;
  # specular = specular * environment map
  MUL      specular, base, specular;
  # diffuse = diffuse * environment map
  MUL      diffuse, base, diffuse;
  # outColor = (specular * environment map) + (diffuse * environment map)
  ADD      base, specular, diffuse;
  # Apply point light attenutaion
  MUL      oCol, base, atten.r;
  END
```

Revision History

```
    Date: 8/22/2003
    Revision: 26
       - Added list of commands generating errors when active texture
         unit selector is out of range.
       - Fixed typo in <stateMatrixItem> rule.
       - Clarified behavior of fragment.position.z with respect to depth
         offset.

    Date: 2/26/2003
    Revision: 25
       - Fixed description of KIL instruction to reflect less than zero
         test, not less than or equal to zero.
       - Clarified the processing of incoming and outgoing depths and
         colors to reflect the conversion to floating-point on input and
         the conversion to fixed-point on output.

    Date: 1/10/2003
    Revision: 24
       - Fixed bug where "state.matrix.mvp" was specified incorrectly.
         It should be P*M0 rather than M0*P.
       - Added issue warning about CMP opcode's order of operands.

    Date: 10/22/2002
    Revision: 23
       - Fixed reference to <extSwizComp> rule in 3.11.5.28.  Instead
         reference both <xyzwExtSwizComp> and <rgbaExtSwizComp> rules.

    Date: 10/02/2002
    Revision: 22
       - Fixed typo in section 3.11.1, where 8 program environment and
         8 program local parameters are listed as the minimums instead
         of 24 of each.  Table X.10 had the correct values.
       - Fixed <stateTexEnvItem> to refer to legacy texture units.
       - Fixed typos in issue 29 pseudo-code, added some clarification.

    Date: 9/19/2002
    Revision: 21
       - Added clarifying paragraph for native texture indirection
         counting, offering examples of possible cases where texture
         indirections may be increased.
       - Fixed typos in issues 25 and 29.

    Date: 9/16/2002
    Revision: 20
       - Added precision hint program options.
       - Fixed various typos, reworded some parts for consistency.
       - Updated issues list.
```

```
Date: 9/13/2002
Revision: 19
   - Promoted minimum precision of texture coordinates in 2.1.1.
   - Added ARB_fog_* program options.
   - Removed modification to 3.9, put clamps in 3.11.4.4.
   - Made 'texture' a reserved keyword in the grammar.
   - Fixed various typos.
   - Updated section 3.11.6.
   - Updated issues list.

Date: 9/11/2002
Revision: 18
   - Updated for consistency with ARB_vertex_program revision 36.
   - Depth output moved to 3rd component of result.depth.
   - Fixed various typos, reworded things in many places.
   - Added NV_fragment_program interactions.
   - Updated issues list.

Date: 9/09/2002
Revision: 17
   - Added fogcoord and position attributes.
   - Moved fragment program section to 3.11, after fog.
   - Changed MAX_TEXTURE_UNITS/MAX_AUX_TEXTURE_UNITS to
     MAX_TEXTURE_COORDS/MAX_TEXTURE_IMAGE_UNITS.
   - Removed TRC and MOD instructions.
   - Added SIN and COS instructions.
   - Added more clarity to resource consumption wording.
   - Added invariance wording concerning depth-replacement.
   - Added rule that a program that fails to load must always fail to
     load, regardless of GL state.
   - Updated issues list.

Date: 8/30/2002
Revision: 16
   - Improved texture indirection description.
   - Defined result of sample from incomplete texture as (0,0,0,1).
   - Removed PROGRAMS_LOAD_OVER_NATIVE_LIMITS_ARB per-target query.
   - Allowed ProgramStringARB to fail on non-native programs.
   - Updated issues list.

Date: 8/28/2002
Revision: 15
   - Updated for consistency with ARB_vertex_program revision 35.
   - Added PROGRAMS_LOAD_OVER_NATIVE_LIMITS_ARB per-target query.
   - Changed MAX_AUX_TEXTURE_UNITS_ARB enum value.
   - Updated issues list.

Date: 8/22/2002
Revision: 14
   - Added sine/cosine instruction (SCS).
   - Updated texture sample grammar, replaced texenables hierarchy.
   - Added EXT_vertex_weighting and ARB_vertex_blend dependency.
   - Updated issues list.
```

```
Date: 8/14/2002
Revision: 13
   - Fixed <paramConstant> grammar rule.
   - Updated issues list.

Date: 8/06/2002
Revision: 12
   - Fixed various typos.
   - Updated issues list.
   - Added wording to 3.10.3.6 to reflect that native resource
     consumption may increase due to emulated instructions.

Date: 7/29/2002
Revision: 11
   - Updated for consistency with ARB_vertex_program revision 34.
   - Added support for matrix binding.
   - Removed precision queries.
   - Updated issues list.

Date: 7/16/2002
Revision: 10
   - Updated for consistency with ARB_vertex_program revision 31.
   - Added fog params and depth range bindings to grammar.
   - Removed stpq writemasks and swizzles from grammar.
   - Required swizzle components to come from same set, xyzw or rgba.

Date: 7/10/2002
Revision: 9
   - Made fog params and depth range bindable.
   - Changed texture instruction names to match 3-letter format.
   - Made texture instructions more consistent with ALU instructions.
   - Increased minimums for implementation-dependent values.
   - Re-introduced 4-components swizzles and the SWZ instruction.
   - Updated issues list.

Date: 7/03/2002
Revision: 8
   - Fixed typos.
   - Added DST, LIT, SGE, SLT instructions.
   - Changed FRC definition to match ARB_vertex_program, added MOD
     instruction to expose fmod(arg, 1.0) behavior.

Date: 6/25/2002
Revision: 7
   - Updated for consistency with ARB_vertex_program revision 29.

Date: 6/19/2002
Revision: 6
   - Updated for consistency with ARB_vertex_program revision 28.
   - Changed from ATI to ARB prefix/suffix.
   - Started using single integer revision number.
   - Added a few more issues to the list.

Date: 6/14/2002
Revision: 1.4
   - Updated for consistency with ARB_vertex_program revision 27.
   - Added a few more issues to the list.
```

```
    Date: 6/05/2002
    Revision: 1.3
       - Updated for consistency with ARB_vertex_program revision 26.
       - Incorporated program object management, removing dependency on
         ARB_vertex_program.
       - Added interaction with ARB_shadow.

    Date: 6/03/2002
    Revision: 1.2
       - Updated for consistency with ARB_vertex_program revision 25.
       - Fixed TexInstructions to use <texSrcReg>, i.e. no parameters.
       - Added TRC, POW, DPH instructions, updated FRC and LRP.
       - Added fog color parameter binding.

    Date: 5/23/2002
    Revision: 1.1
       - Updated for consistency with ARB_vertex_program revision 24.
       - Added GetProgramfvATI entrypoint for querying precision values.

    Date: 5/10/2002
    Revision: 1.0
       - First draft for circulation.
```

Name

    ARB_fragment_program_shadow

Name Strings

    GL_ARB_fragment_program_shadow

IP Status

    Unknown, but Microsoft claims to own intellectual property
    related to ARB_fragment_program. This extension is
    an extension to ARB_fragment_program.

Status

    Complete. Approved by ARB on December 16, 2003

Version

    Last Modified Date: December 8, 2003
    Revision: 5

Number

    ARB Extension #36

Dependencies

    The extension is written against the OpenGL 1.3 Specification.

    ARB_fragment_program is required.

    ARB_shadow is required.

    EXT_texture_rectange affects the definition of this extension.

Overview

    This extension extends ARB_fragment_program to remove
    the interaction with ARB_shadow.

    This extension defines the program option
    "ARB_fragment_program_shadow".

    If a fragment program specifies the option
    "ARB_fragment_program_shadow"

        SHADOW1D, SHADOW2D, SHADOWRECT

    are added as texture targets. When shadow map comparisons are
    desired, specify the SHADOW1D, SHADOW2D, or SHADOWRECT texture
    targets in texture instructions.

    Programs must assure that the comparison mode for each depth
    texture (TEXTURE_COMPARE_MODE) and/or the internal texture
    format (DEPTH_COMPONENT) and the targets of the texture lookup

instructions match. Otherwise, if the comparison mode
and/or the internal texture format are inconsistent with the
texture target, the results of the texture lookup are undefined.

Issues

(1) What should this extension be called?

RESOLVED: ARB_fragment_program_shadow. Shadow support
is the only new feature. The name ARB_fragment_program2
should be used for a far more major revision to
ARB_fragment_program. ARB_fragment_program1_1 is
less descriptive.

*(2) Should this extension use the header string "!!ARBfp1.1" or
a program option "ARB_fragment_program_shadow"?*

RESOLVED: Program option "ARB_fragment_program_shadow".

(3) What form should the ARB_fragment_program_shadow option take?

a. New sampler instructions.
```
SHX result.color.a, fragment.texcoord[1], texture[0], 2D;
```

b. New texture modifiers.
```
TEX result.color.a, fragment.texcoord[1], texture[0], 2D,SHADOW;
```

c. New texture targets.
```
TEX result.color.a, fragment.texcoord[1], texture[0], SHADOW2D;
```

d. New sampler instructions AND new texture modifiers.
```
SHX result.color.a, fragment.texcoord[1], texture[0], 2D,SHADOW;
```

e. New sampler instructions AND new texture targets.
```
SHX result.color.a, fragment.texcoord[1], texture[0], SHADOW2D;
```

RESOLVED: Choose the simplest option c, add new texture targets.

All of the above forms are functionally equivalent.

An earlier draft proposed option a, adding six new shadow
instructions. The required shadow instructions are
three variants of shadow instruction (non-projective, projective,
and biased), and the same instructions with the modifier _SAT.

Option b adds texture modifiers but requires additional semantic
restrictions.

Option c adds texture targets only. It is a sufficient
and simple change to one grammar rule.

Option d and e are listed for completeness. They require
additional instructions and additional semantic restrictions.

Note that option e is most similar to the resolution of this issue
by ARB_fragment_shader and the OpenGL Shading Language. The OpenGL
Shading Language has both built-in texture and shadow functions and

sampler types, analogous to texture instructions and texture targets. The resolution here drops the added reduntancy and potential error checking in favor of simplicity, but is otherwise consistent. This resolution is also consistent with the precident already established in ARB_fragment_program, since we have a TEX instruction, not a TEX1D, TEX2D, TEXCUBE, TEX3D, TEXRECT instructions.

(4) How should ARB_fragment_program_shadow function?

a. Simply remove the interaction with ARB_shadow so that TEXTURE_COMPARE_MODE behaves exactly as specified in the OpenGL 1.4 specification.

b. Add "SHADOW" targets to texture lookup instructions. TEXTURE_COMPARE_MODE is ignored. For samples from a SHADOW target TEXTURE_COMPARE_MODE is treated as COMPARE_R_TO_TEXTURE; otherwise, it is treated as NONE.

c. Like (b), but with undefined results if TEXTURE_COMPARE_MODE and/or the internal format of the texture does not match the target.

d. A hybrid of (a) and (b), where the SHADOW target means to use the TEXTURE_COMPARE_MODE state.

RESOLVED - Option c, undefined behavior when the target and mode do not match.

Program text is not simply loaded, it is compiled, optimized and then loaded. Options a and d would remove information from the optimizer. Which components of the texture coordinate are required for the sample? Specifically, is the r component of the texture coordinate required? Options b and c are both sufficient and retain the information required by optimizers. Option c is consistent with the resolution chosen by ARB_fragment_shader.

(5) What if additional texture compare modes are added by future extensions to ARB_SHADOW?

We do not anticipate future extensions adding additional texture compare modes. Only the additional mode COMPARE_T_TO_TEXTURE has even marginal utility, and then only for SHADOW1D targets. However, a future extension adding additional texture compare modes is not precluded. The language in this specification is carefully, if somewhat awkwardly, written to say the TEXTURE_COMPARE_MODE either "is NONE" or "is not NONE.

(6) Does EXT_shadow_funcs interact with this extension?

RESOLVED: It doesn't. ARB_shadow supports LEQUAL or GEQUAL comparison functions. EXT_shadow_funcs simply adds the additional functions LESS, GREATER, EQUAL, NOTEQUAL, ALWAYS, and NEVER. Whichever function is specified will be used for the comparison function.

(7) Does ARB_shadow_ambient interact with this extension?

RESOLVED: It doesn't. ARB_shadow returns a result in the range [0,1]. ARB_shadow_ambient simply maps this range to [TEXTURE_COMPARE_FAIL_ARB, 1]. The result will be returned in the specified range.

(8) How would an existing fragment program be ported to use the program option ARB_fragment_program_shadow?

RESOLVED: Fairly simply, but with a caveat on undefined behavior.

```
!!ARBfp1.0
# A simple example of shadow map (R <= Dt)
#
# SHOULD make sure that the 2D texture bound to texture unit 0:
#    texture format of DEPTH_COMPONENT (for highest quality comparison)
#    TEXTURE_MAG_FILTER is NEAREST
#    TEXTURE_MIN_FILTER is NEAREST or NEAREST_MIPMAP_NEAREST
# Assumes DEPTH_TEXTURE_MODE is LUMINANCE or INTENSITY
#
TEMP Result;
ALIAS Dt = Result;
TEX Dt, fragment.texcoord[0], texture[0], 2D;
SGE Result, Dt.x, fragment.texcoord[0].z;      # R <= Dt

!!ARBfp1.0
OPTION ARB_fragment_program_shadow;
# A simple example of shadow map (R<= Dt)
#
# MUST make sure that the 2D texture bound to texture unit 0:
#    texture format of DEPTH_COMPONENT and a
#    TEXTURE_COMPARE_MODE of COMPARE_R_TO_TEXTURE
# Otherwise, the Result is undefined.
#
# Remember also that to get R <= Dt to set:
#    TEXTURE_COMPARE_FUNC of LEQUAL
#
# A single compare equivalent to the above example will result if:
#    TEXTURE_MAG_FILTER is NEAREST
#    TEXTURE_MIN_FILTER is NEAREST or NEAREST_MIPMAP_NEAREST
# Otherwise, percent closer filtering may be applied.
#
TEMP Result;
TEX Result, fragment.texcoord[0], texture[0], SHADOW2D;
```

Additions to Chapter 2 of the OpenGL 1.3 Specification (OpenGL Operation)

None

Additions to Chapter 3 of the OpenGL 1.3 Specification (Rasterization)

Modify Section 3.11.2 Fragment Program Grammar and Semantic Restrictions

Replace <texTarget> grammar rule with

```
<texTarget>             ::= "1D"
                          | "2D"
                          | "3D"
                          | "CUBE"
                          | "RECT"
                          | <shadowTarget> (if program option is present)

<shadowTarget>          ::= "SHADOW1D"
                          | "SHADOW2D"
                          | "SHADOWRECT"
```

Add Section 3.11.4.5.3 Fragment Program Shadow Option

If a fragment program specifies the "ARB_fragment_program_shadow" program option, the <texTarget> rule is modified to add the texture targets SHADOW1D, SHADOW2D and SHADOWRECT (See Section 3.11.2).

Modify Section 3.11.6 Fragment Program Texture Instruction Set

(replace 1st through 4th paragraphs with the following paragraphs)

The first three texture instructions described below specify the mapping of 4-tuple input vectors to 4-tuple output vectors. The sampling of the texture works as described in section 3.8, except that texture environments and texture functions are not applicable, and the texture enables hierarchy is replaced by explicit references to the desired texture target (i.e., 1D, 2D, 3D, cube map, rectangle). These texture instructions specify how the 4-tuple is mapped into the coordinates used for sampling. The following function is used to describe the texture sampling in the descriptions below:

```
  vec4 TextureSample(float s, float t, float r, float lodBias,
                     int texImageUnit, enum texTarget);
```

Note that not all three texture coordinates, s, t, and r, are used by all texture targets. In particular, 1D texture targets only use the s component. 2D and RECT (non-power-of-two) texture targets only use the s and t components. SHADOW1D texture targets only use the s and r components. The descriptions of the texture instructions below supply all three components, as would be the case with CUBE, 3D, SHADOW2D, and SHADOWRECT targets.

If a fragment program samples from a texture target on a texture image unit where the bound texture object is not complete, as defined in section 3.8.9, the result will be the vector (R, G, B, A) = (0, 0, 0, 1).

If a fragment program does not specify the "ARB_fragment_program_shadow" program option, and if a fragment

    program samples from a texture target of 1D, 2D, or RECT, it is as
    if TEXTURE_COMPARE_MODE_ARB is NONE.

    If a fragment program specifies the "ARB_fragment_program_shadow"
    program option, the result returned of a sample from a texture target
    on a texture image unit is undefined if:

```
      the texture target is 1D, 2D, or RECT, and
      the texture object's internal format is DEPTH_COMPONENT_ARB, and
      the TEXTURE_COMPARE_MODE_ARB is not NONE;
```

    or

```
      the texture target is SHADOW1D, SHADOW2D, SHADOWRECT, and
        the texture object's internal format is DEPTH_COMPONENT_ARB, and
      the TEXTURE_COMPARE_MODE_ARB is NONE;
```

    or

```
      the texture target is SHADOW1D, SHADOW2D, SHADOWRECT, and
        the texture object's internal format is not DEPTH_COMPONENT_ARB.
```

    A fragment program will fail to load if it attempts to sample from
    multiple texture targets on the same texture image unit. For example,
    the following programs would fail to load:

```
      !!ARBfp1.0
      TEX result.color.rgb, fragment.texcoord[0], texture[0], 2D;
      TEX result.color.a,   fragment.texcoord[1], texture[0], 3D;
      END

      !!ARBfp1.0
      OPTION ARB_fragment_program_shadow;
      TEX result.color.rgb, fragment.texcoord[0], texture[0], 2D;
      TEX result.color.a,   fragment.texcoord[1], texture[0], SHADOW2D;
      END
```

Status

    Complete. Appprove by the ARB on October 22, 2004.

Version

    Last Modified Date: October 1, 2004
    Version: 6

Number

    ARB Extension #40

Dependencies

    This extension is written against the OpenGL 2.0 Specification
    but will work with the OpenGL 1.5 Specification.

    Based on the NV_half_float extension.

    This extension interacts with ARB_color_buffer_float.

Overview

    This extension introduces a new data type for half-precision (16-bit)
    floating-point quantities. The floating-point format is very similar
    to the IEEE single-precision floating-point standard, except that it
    has only 5 exponent bits and 10 mantissa bits. Half-precision floats
    are smaller than full precision floats and provide a larger dynamic
    range than similarly sized normalized scalar data types.

    This extension allows applications to use half-precision floating-
    point data when specifying pixel data. It extends the existing image
    specification commands to accept the new data type.

    Floating-point data is clamped to [0, 1] at various places in the
    GL unless clamping is disabled with the ARB_color_buffer_float
    extension.

IP Status

SGI owns US Patent #6,650,327, issued November 18, 2003. SGI believes this patent contains necessary IP for graphics systems implementing floating point (FP) rasterization and FP framebuffer capabilities.

SGI will not grant the ARB royalty-free use of this IP for use in OpenGL, but will discuss licensing on RAND terms, on an individual basis with companies wishing to use this IP in the context of conformant OpenGL implementations. SGI does not plan to make any special exemption for open source implementations.

Contact Doug Crisman at SGI Legal for the complete IP disclosure.

Issues

1. *How is this extension different from the NV_half_float extension?*

   This extension does not add new commands for specifying half-precision vertex data, and all imaging functions have been listed for supporting the "half" type.

2. *What should the new data type be called? "half"? "hfloat"?*

   RESOLVED: half . This convention builds on the convention of using the type "double" to describe double-precision floating-point numbers. Here, "half" will refer to half-precision floating-point numbers.

   Even though the 16-bit float data type is a first-class data type, it is still more problematic than the other types in the sense that no native programming languages support the data type. "hfloat/hf" would have reflected a second-class status better than "half/h".

   Both names are not without conflicting precedents. The name "half" is used to connote 16-bit scalar values on some 32-bit CPU architectures (e.g., PowerPC). The name "hfloat" has been used to describe 128-bit floating-point data on VAX systems.

3. *Should half-precision data be accepted by commands in the imaging subset that accept pixel data?*

   RESOLVED: Yes, all functions in the core OpenGL and the imaging subset that accept pixel data accept half-precision data.

4. *Should the special representations NaN, INF, and denormal be supported?*

   RESOLVED: Implementation dependent. The spec reflects that Nan and INF produce unspecified results. Denormalized numbers can be treated as a value of 0.

New Tokens

    SeparableFilter2D, GetSeparableFilter, ColorTable, ColorSubTable,
    and GetColorTable:

        HALF_FLOAT_ARB   0x140B

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

Add a new Section 2.1.2, (p. 6):

2.1.2 16-Bit Floating-Point Numbers

A 16-bit floating-point number has a 1-bit sign (S), a 5-bit exponent (E), and a 10-bit mantissa (M). The value of a 16-bit floating-point number is determined by the following:

```
    (-1)^S * 0.0,                        if E == 0 and M == 0,
    (-1)^S * 2^-14 * (M / 2^10),         if E == 0 and M != 0,
    (-1)^S * 2^(E-15) * (1 + M/2^10),    if 0 < E < 31,
    (-1)^S * INF,                        if E == 31 and M == 0, or
    NaN,                                 if E == 31 and M != 0,
```

where

```
    S = floor((N mod 65536) / 32768),
    E = floor((N mod 32768) / 1024), and
    M = N mod 1024.
```

Implementations are also allowed to use any of the following alternative encodings:

```
    (-1)^S * 0.0,                        if E == 0 and M != 0,
    (-1)^S * 2^(E-15) * (1 + M/2^10),    if E == 31 and M == 0, or
    (-1)^S * 2^(E-15) * (1 + M/2^10),    if E == 31 and M != 0,
```

Any representable 16-bit floating-point value is legal as input to a GL command that accepts 16-bit floating-point data. The result of providing a value that is not a floating-point number (such as infinity or NaN) to such a command is unspecified, but must not lead to GL interruption or termination. Providing a denormalized number or negative zero to GL must yield predictable results.

(modify Table 2.2, p. 9) -- add new row

GL Type	Minimum Bit Width	Description
half	16	half-precision floating-point value encoded in an unsigned scalar

Modify Section 2.14, (Colors and Coloring), p. 59

(modify Table 2.9, p. 59) Add new row to the table:

GL Type	Conversion
half	c

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

Modify Section 3.6.4, Rasterization of Pixel Rectangles (p. 126)

(modify Table 3.5, p. 128 -- add new row)

type Parameter Token Name	Corresponding GL Data Type	Special Interpretation
HALF_FLOAT_ARB	half	No

(modify Unpacking, p. 129) Data are taken from host memory as a sequence of signed or unsigned bytes (GL data types byte and ubyte), signed or unsigned integers (GL data types int and uint), or floating-point values (GL data types half and float).

Additions to Chapter 4 of the OpenGL 2.0 Specification (Per-Fragment Operations and the Framebuffer)

Modify Section 4.3.2, Reading Pixels (p. 219)

(modify Final Conversion, p. 222) For an index, if the type is not FLOAT or HALF_FLOAT_ARB, final conversion consists of masking the index with the value given in Table 4.6; if the type is FLOAT or HALF_FLOAT_ARB, then the integer index is converted to a GL float or half data value.

(modify Table 4.7, p. 224 -- add new row)

    Last Modified Date: December 15, 1999
    Author Revision: 0.5

    Based on: SGIS_Multisample Specification
               Date: 1994/11/22 Revision: 1.14

Number

    ARB Extension #5

Dependencies

    WGL_EXT_extensions_string is required.
    WGL_EXT_pixel_format is required.

Overview

This extension provides a mechanism to antialias all GL primitives: points, lines, polygons, bitmaps, and images. The technique is to sample all primitives multiple times at each pixel. The color sample values are resolved to a single, displayable color each time a pixel is updated, so the antialiasing appears to be automatic at the application level. Because each sample includes depth and stencil information, the depth and stencil functions perform equivalently to the single-sample mode.

An additional buffer, called the multisample buffer, is added to the framebuffer. Pixel sample values, including color, depth, and stencil values, are stored in this buffer. When the framebuffer includes a multisample buffer, it does not also include separate depth or stencil buffers, even if the multisample buffer does not store depth or stencil values. Color buffers (left/right, front/ back, and aux) do coexist with the multisample buffer, however.

Multisample antialiasing is most valuable for rendering polygons, because it requires no sorting for hidden surface elimination, and it correctly handles adjacent polygons, object silhouettes, and even intersecting polygons. If only points or lines are being rendered, the "smooth" antialiasing mechanism provided by the base GL may result in a higher quality image. This extension is

designed to allow multisample and smooth antialiasing techniques
to be alternated during the rendering of a single scene.

IP Status

TBD

Issues

1. Multiple passes have been taken out. Is this acceptable?

   RESOLUTION: Yes. This can be added back with an additional
   extension if needed.

2. Would SampleAlphaARB be a better name for the function
   SampleMaskARB? If so, the name SAMPLE_MASK_ARB should also be
   changed to SAMPLE_ALPHA_ARB.

   RESOLUTION: Names containing "mask" were changed to use
   "coverage" instead.

3. Should the SampleCoverageARB function be changed to allow
   blending between more than two objects?

   RESOLUTION: Not addressed by this extension. An additional
   extension has been proposed that allows a coverage range for
   each object. The coverage range is a min and max value that
   can be used to blend multiple objects at different level-of-
   detail fading. The SampleCoverageARB function will layer on
   this new extension.

New Procedures and Functions

```
void SampleCoverageARB(clampf value,
                       boolean invert);
```

New Tokens

Accepted by the <attribList> parameter of glXChooseVisual, and by
the <attrib> parameter of glXGetConfig:

```
GLX_SAMPLE_BUFFERS_ARB              100000
GLX_SAMPLES_ARB                     100001
```

Accepted by the <piAttributes> parameter of
wglGetPixelFormatAttribivEXT, wglGetPixelFormatAttribfvEXT, and
the <piAttribIList> and <pfAttribIList> of wglChoosePixelFormatEXT:

```
WGL_SAMPLE_BUFFERS_ARB              0x2041
WGL_SAMPLES_ARB                     0x2042
```

    Accepted by the <cap> parameter of Enable, Disable, and IsEnabled,
    and by the <pname> parameter of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

MULTISAMPLE_ARB	0x809D
SAMPLE_ALPHA_TO_COVERAGE_ARB	0x809E
SAMPLE_ALPHA_TO_ONE_ARB	0x809F
SAMPLE_COVERAGE_ARB	0x80A0

    Accepted by the <mask> parameter of PushAttrib:

MULTISAMPLE_BIT_ARB	0x20000000

    Accepted by the <pname> parameter of GetBooleanv, GetDoublev,
    GetIntegerv, and GetFloatv:

SAMPLE_BUFFERS_ARB	0x80A8
SAMPLES_ARB	0x80A9
SAMPLE_COVERAGE_VALUE_ARB	0x80AA
SAMPLE_COVERAGE_INVERT_ARB	0x80AB

Additions to Chapter 2 of the 1.2.1 Specification (OpenGL Operation)

None

Additions to Chapter 3 of the 1.2.1 Specification (Rasterization)

If SAMPLE_BUFFERS_ARB is a value of one, the rasterization of all GL primitives is changed, and is referred to as multisample rasterization. Otherwise, primitive rasterization operates as it is described in the GL specification, and is referred to as single-sample rasterization. The value of SAMPLE_BUFFERS_ARB is an implementation dependent constant, and is queried by calling GetIntegerv with <pname> set to SAMPLE_BUFFERS_ARB. This value is the same as GLX_SAMPLE_BUFFERS_ARB or WGL_SAMPLE_BUFFERS_ARB for the visual or pixel format associated with the context.

During multisample rendering the contents of a pixel fragment are changed in two ways. First, each fragment includes a coverage value with SAMPLES_ARB bits. The value of SAMPLES_ARB is an implementation-dependent constant, and is queried by calling GetIntegerv with <pname> set to SAMPLES_ARB. Second, each fragment includes SAMPLES_ARB depth values, instead of the single depth value that is maintained in single-sample rendering mode. Each pixel fragment thus consists of integer x and y grid coordinates, a color, SAMPLES_ARB depth values, texture coordinates, and a coverage value with a maximum of SAMPLES_ARB bits.

The behavior of multisample rasterization is a function of MULTISAMPLE_ARB, which is enabled and disabled by calling Enable or Disable, with <cap> set to MULTISAMPLE_ARB. Its value is queried using IsEnabled, with <cap> set to MULTISAMPLE_ARB.

If MULTISAMPLE_ARB is disabled, multisample rasterization of all primitives is equivalent to single-sample rasterization, except that the fragment coverage value is set to full coverage. The depth values may all be set to the single value that would have been assigned by single-sample rasterization, or they may be assigned as described below for multisample rasterization.

If MULTISAMPLE_ARB is enabled, multisample rasterization of all primitives differs substantially from single-sample rasterization. It is understood that each pixel in the framebuffer has SAMPLES_ARB locations associated with it. These locations are exact positions, rather than regions or areas, and each is referred to as a sample point. The sample points associated with a pixel may be located inside or outside of the unit square that is considered to bound the pixel. Furthermore, the relative locations of sample points may be identical for each pixel in the framebuffer, or they may differ.

If the sample locations differ per pixel, they should be aligned to window, not screen, boundaries. Otherwise rendering results will be window-position specific. The invariance requirement described in section 3.1 is relaxed for all enabled multisample rendering, because the sample locations may be a function of pixel location.

It is not possible to query the actual sample locations of a pixel.

Point Multisample Rasterization
[Insert before section 3.3.1]

If MULTISAMPLE_ARB is enabled, and SAMPLE_BUFFERS_ARB is a value of one, then points are rasterized using the following algorithm, regardless of whether point antialiasing (POINT_SMOOTH) is enabled or disabled. Point rasterization produces a fragment for each framebuffer pixel with one or more sample points that intersect the region lying within the circle having diameter equal to the current point width and centered at the point's (Xw,Yw). Coverage bits that correspond to sample points that intersect the circular region are 1, other coverage bits are 0. All depth values of the fragment are assigned the depth value of the point being rasterized. Other data associated with each fragment are the data associated with the point being rasterized.

Point size range and number of gradations are equivalent to those supported for antialiased points.

Line Multisample Rasterization
[Insert before section 3.4.3]

If MULTISAMPLE_ARB is enabled, and SAMPLE_BUFFERS_ARB is a value of one, then lines are rasterized using the following algorithm, regardless of whether line antialiasing (LINE_SMOOTH) is enabled or disabled. Line rasterization produces a fragment for each framebuffer pixel with one or more sample points that intersect the rectangular region that is described in the Antialiasing section of 3.4.2 (Other Line Segment Features). If line stippling is enabled, the rectangular region is subdivided into adjacent unit-length rectangles, with some rectangles eliminated according to the procedure given under Line Stipple, where "fragment" is replaced by "rectangle".

Coverage bits that correspond to sample points that intersect a retained rectangle are 1, other coverage bits are 0. Each depth value is produced by substituting the corresponding sample location into equation 3.1, then using the result to evaluate equation 3.3. The data associated with each fragment are otherwise computed by evaluating equation 3.1 at the fragment center, then substituting into equation 3.2.

Line width range and number of gradations are equivalent to those supported for antialiased lines.

Polygon Multisample Rasterization
[Insert before section 3.5.6]

If MULTISAMPLE_ARB is enabled, and SAMPLE_BUFFERS_ARB is a value of one, then polygons are rasterized using the following algorithm, regardless of whether polygon antialiasing (POLYGON_SMOOTH) is enabled or disabled. Polygon rasterization produces a fragment for each framebuffer pixel with one or more sample points that satisfy the point sampling criteria described in section 3.5.1, including the special treatment for sample points that lie on a polygon boundary edge. If a polygon is culled, based on its orientation and the CullFace mode, then no fragments are produced during rasterization. Fragments are culled by the polygon stipple just as they are for aliased and antialiased polygons.

Coverage bits that correspond to sample points that satisfy the point sampling criteria are 1, other coverage bits are 0. Each depth value is produced by substituting the corresponding sample location into the barycentric equations described in section 3.5.1, using the approximation to equation 3.4 that omits w components. The data associated with each fragment are otherwise computed by barycentric evaluation using the fragment's center point.

The rasterization described above applies only to the FILL state of PolygonMode. For POINT and LINE, the rasterizations described in the Point Multisample Rasterization and the Line Multisample Rasterization sections apply.

Pixel Rectangle Multisample Rasterization
[Insert before section 3.6.5]

If MULTISAMPLE_ARB is enabled, and SAMPLE_BUFFERS_ARB is a value of one, then pixel rectangles are rasterized using the following algorithm. Let (Xrp,Yrp) be the current raster position. (If the current raster position is invalid, then DrawPixels is ignored.) If a particular group (index or components) is the nth in a row and belongs to the mth row, consider the region in window coordinates bounded by the rectangle with corners

```
  (Xrp + Zx*n, Yrp + Zy*m)
```

and

```
  (Xrp + Zx*(n+1), Yrp + Zy*(m+1))
```

where Zx and Zy are the pixel zoom factors specified by PixelZoom, and may each be either positive or negative. A fragment representing group n,m is produced for each framebuffer pixel with one or more sample points that lie inside, or on the bottom or left boundary, of this rectangle. Each fragment so produced takes its associated data from the group and from the current raster position, in a manner consistent with the discussion in the Conversion to Fragments subsection of section 3.6.4 of the GL specification. All depth sample values are assigned the same value, taken either from the group (if it is a depth component group) or from the current raster position (if it is not).

A single pixel rectangle will generate multiple, perhaps very many fragments for the same framebuffer pixel, depending on the pixel zoom factors.

Bitmap Multisample Rasterization
[Insert at the end section 3.7]

If MULTISAMPLE_ARB is enabled, and SAMPLE_BUFFERS_ARB is a value of one, then bitmaps are rasterized using the following algorithm. If the current raster position is invalid, the bitmap is ignored. Otherwise, a screen-aligned array of pixel-size rectangles is constructed, with its lower-left corner at (Xrp,Yrp), and its upper right corner at (Xrp+w,Yrp+h), where w and h are the width and height of the bitmap. Rectangles in this array are eliminated if the corresponding bit in the bitmap is zero, and are retained otherwise. Bitmap rasterization produces a fragment for each framebuffer pixel with one or more sample points either inside or on the bottom or left edge of a retained rectangle.

Coverage bits that correspond to sample points either inside or on the bottom or left edge of a retained rectangle are 1, other coverage bits are 0. The associated data for each fragment are those associated with the current raster position. Once the fragments have been produced, the current raster position is updated exactly as it is in the single-sample rasterization case.

Additions to Chapter 4 of the 1.2.1 Specification (Per-Fragment Operations and the Frame Buffer)

Multisample Fragment Operations
[Insert after section 4.1.2]

This step modifies fragment alpha and coverage values based on the values of SAMPLE_ALPHA_TO_COVERAGE_ARB, SAMPLE_ALPHA_TO_ONE_ARB, SAMPLE_COVERAGE_ARB, SAMPLE_COVERAGE_VALUE_ARB, and SAMPLE_COVERAGE_INVERT_ARB. No changes to the fragment alpha or coverage values are made at this step if MULTISAMPLE_ARB is disabled, or if SAMPLE_BUFFERS_ARB is not a value of one.

SAMPLE_ALPHA_TO_COVERAGE_ARB, SAMPLE_ALPHA_TO_ONE_ARB, and SAMPLE_COVERAGE_ARB are enabled and disabled by calling Enable and Disable with <cap> specified as one of the three token values. All three values are queried by calling IsEnabled, with <cap> set to the desired token value. If SAMPLE_ALPHA_TO_COVERAGE_ARB is enabled, the fragment alpha value is used to generate a temporary coverage value, which is then ANDed with the fragment coverage value. Otherwise the fragment coverage value is unchanged at this point.

This specification does not require a specific algorithm for converting an alpha value to a temporary coverage value. It is intended that the number of 1's in the temporary coverage be proportional to the alpha value, with all 1's corresponding to the maximum alpha value, and all 0's corresponding to an alpha value of 0. It is also intended that the algorithm be pseudo-random in nature, to avoid image artifacts due to regular coverage sample locations. The algorithm can and probably should be different at different pixel locations. If it does differ, it should be defined relative to window, not screen, coordinates, so that rendering results are invariant with respect to window position.

Next, if SAMPLE_ALPHA_TO_ONE_ARB is enabled, fragment alpha is replaced by the maximum representable alpha value. Otherwise, fragment alpha value is not changed.

Finally, if SAMPLE_COVERAGE_ARB is enabled, the fragment coverage is ANDed with another temporary coverage. This temporary coverage is generated in the same manner as the one described above, but as a function of the value of SAMPLE_COVERAGE_VALUE_ARB. The function need not be identical, but it must have the same properties of proportionality and invariance. If SAMPLE_COVERAGE_INVERT_ARB is TRUE, the temporary coverage is inverted (all bit values are inverted) before it is ANDed with the fragment coverage.

The values of SAMPLE_COVERAGE_VALUE_ARB and SAMPLE_COVERAGE_INVERT_ARB are specified simultaneously by calling SampleCoverageARB, with <value> set to the desired coverage value, and <invert> set to TRUE or FALSE. <value> is clamped to [0,1] before being stored as SAMPLE_COVERAGE_VALUE_ARB. SAMPLE_COVERAGE_VALUE_ARB is queried by calling GetFloatv with <pname> set to SAMPLE_COVERAGE_VALUE_ARB. SAMPLE_COVERAGE_INVERT_ARB is queried by calling GetBooleanv with <pname> set to SAMPLE_COVERAGE_INVERT_ARB.

Multisample Fragment Operations
[Insert after section 4.1.8]

If the DrawBuffers mode is NONE, no change is made to any multisample or color buffer. Otherwise, fragment processing is as described below.

If MULTISAMPLE_ARB is enabled, and SAMPLE_BUFFERS_ARB is one, the stencil test, depth test, blending, and dithering operations are performed for each pixel sample, rather than just once for each fragment. Failure of the stencil or depth test results in termination of the processing of that sample, rather than discarding of the fragment. All operations are performed on the color, depth, and stencil values stored in the multisample buffer (to be described in a following section). The contents of the color buffers are not modified at this point.

Stencil, depth, blending, and dithering operations are performed for a pixel sample only if that sample's fragment coverage bit is a value of 1. If the corresponding coverage bit is 0, no operations are performed for that sample. Depth operations use the fragment depth value that is specific for each sample. The single fragment color value is used for all sample operations, however, as is the current stencil value.

If MULTISAMPLE_ARB is disabled, and SAMPLE_BUFFERS_ARB is one, the fragment may be treated exactly as described above, with optimization possible because the fragment coverage must be set to full coverage. Further optimization is allowed, however. An implementation may choose to identify a centermost sample, and to perform stencil and depth tests on only that sample. Regardless of the outcome of the stencil test, all multisample buffer stencil sample values are set to the appropriate new stencil value. If the depth test passes, all multisample buffer depth sample values are set to the depth of the fragment's centermost sample's depth value, and all multisample buffer color sample values are set to the color value of the incoming fragment. Otherwise, no change is made to any multisample buffer color or depth value.

After all operations have been completed on the multisample buffer, the color sample values are combined to produce a single color value, and that value is written into each color buffer that is currently enabled, based on the DrawBuffers mode. An implementation may defer the writing of the color buffer until a later time, but the state of the framebuffer must behave as if the color buffer was updated as each fragment was processed. The method of combination is not specified, though a simple average computed independently for each color component is recommended.

Fine Control of Multisample Buffer Updates
[Insert at the end of section 4.2.2]

When SAMPLE_BUFFERS_ARB is one, ColorMask, DepthMask, and StencilMask control the modification of values in the multisample buffer. The color mask has no effect on modifications to the color buffers. If the color mask is entirely disabled, the color sample values must still be combined (as described above) and the result used to replace the color values of the buffers enabled by DrawBuffers.

Clearing the Multisample Buffer
[Insert as a subsection for section 4.2.3]

The color samples of the multisample buffer are cleared when one or more color buffers are cleared, as specified by the Clear mask bit COLOR_BUFFER_BIT and the DrawBuffers mode. If the DrawBuffers mode is NONE, the color samples of the multisample buffer cannot be cleared.

Clear mask bits DEPTH_BUFFER_BIT and STENCIL_BUFFER_BIT indicate that the depth and stencil samples of the multisample buffer are to be cleared. If Clear mask bit DEPTH_BUFFER_BIT is specified, and if the DrawBuffers mode is not NONE, then the multisample depth buffer samples are cleared. Likewise, if Clear mask bit STENCIL_BUFFER_BIT is specified, and if the DrawBuffers mode is not NONE, then the multisample stencil buffer is cleared.

Reading Pixels
[These changes are made to the text in section 4.3.2, following the subheading Obtaining Pixels from the Framebuffer.]

Follow the sentence "If there is no depth buffer, the error INVALID_OPERATION occurs." with: If there is a multisample buffer (SAMPLE_BUFFERS_ARB is 1) then values are obtained from the depth samples in this buffer. It is recommended that the depth value of the centermost sample be used, though implementations may choose any function of the depth sample values at each pixel.

Follow the sentence "if there is no stencil buffer, the error INVALID_OPERATION occurs." with: If there is a multisample buffer, then values are obtained from the stencil samples in this buffer. It is recommended that the stencil value of the centermost sample be used, though implementations may choose any function of the stencil sample values at each pixel.

[This extension makes no change to the way that color values are obtained from the framebuffer.]

Additions to Chapter 5 of the 1.2.1 Specification (Special Functions)

None

Additions to Chapter 6 of the 1.2 Specification (State and State Requests)

An additional group of state variables, MULTISAMPLE_BIT_ARB, is defined by this extension. When PushAttrib is called with bit MULTISAMPLE_BIT_ARB set, the multisample group of state variables is pushed onto the attribute stack. When PopAttrib is called, these state variables are restored to their previous values if they were pushed. Some multisample state is included in the ENABLE_BIT group as well. In order to avoid incompatibility with GL implementations that do not support SGIS_multisample, ALL_ATTRIB_BITS does not include MULTISAMPLE_BIT_ARB.

Additions to the GLX Specification

The parameter GLX_SAMPLE_BUFFERS_ARB is added to glXGetConfig. When queried, by calling glXGetConfig with <attrib> set to GLX_SAMPLE_BUFFERS_ARB, it returns the number of multisample buffers included in the visual. For a normal visual, the return value is zero. A return value of one indicates that a single multisample buffer is available. The number of samples per pixel is queried by calling glXGetConfig with <attrib> set to GLX_SAMPLES_ARB. It is understood that the number of color, depth, and stencil bits per sample in the multisample buffer are as specified by the GLX_*_SIZE parameters. It is also understood that there are no single-sample depth or stencil buffers associated with this visual -- the only depth and stencil buffers are those in the multisample buffer. GLX_SAMPLES_ARB is zero if GLX_SAMPLE_BUFFERS_ARB is zero.

glXChooseVisual accepts GLX_SAMPLE_BUFFERS_ARB in <attribList>, followed by the minimum number of multisample buffers that can be accepted. Visuals with the smallest number of multisample buffers that meets or exceeds the specified minimum number are preferred. Currently operation with more than one multisample buffer is undefined, so the returned value will be either zero or one.

glXChooseVisual accepts GLX_SAMPLES_ARB in <attribList>, followed by the minimum number of samples that can be accepted in the multisample buffer. Visuals with the smallest number of samples that meets or exceeds the specified minimum number are preferred.

If the color samples in the multisample buffer store fewer bits than are stored in the color buffers, this fact will not be reported accurately. Presumably a compression scheme is being employed, and is expected to maintain an aggregate resolution equal to that of the color buffers.

GLX Protocol

TBD

Additions to the WGL Specification

The parameter WGL_SAMPLE_BUFFERS_ARB is added to wglGetPixelFormatAttrib*v. When queried, by calling wglGetPixelFormatAttrib*v with <piAttributes> set to WGL_SAMPLE_BUFFERS_ARB, it returns the number of multisample buffers included in the pixel format. For a normal pixel format, the return value is zero. A return value of one indicates that a single multisample buffer is available. The number of samples per pixel is queried by calling wglGetPixelFormatAttrib*v with <piAttributes> set to WGL_SAMPLES_ARB. It is understood that the number of color, depth, and stencil bits per sample in the multisample buffer are as specified by the WGL_*_SIZE parameters. It is also understood that there are no single-sample depth or stencil buffers associated with this visual -- the only depth and stencil buffers are those in the multisample buffer. WGL_SAMPLES_ARB is zero if WGL_SAMPLE_BUFFERS_ARB is zero.

wglChoosePixelFormatEXT accepts WGL_SAMPLE_BUFFERS_ARB in <piAttribIList> and <pfAttribIList> with the corresponding value set to the minimum number of multisample buffers that can be accepted. Pixel formats with the smallest number of multisample buffers that meets or exceeds the specified minimum number are preferred. Currently operation with more than one multisample buffer is undefined, so the returned value will be either zero or one.

If the color samples in the multisample buffer store fewer bits than are stored in the color buffers, this fact will not be reported accurately. Presumably a compression scheme is being employed, and is expected to maintain an aggregate resolution equal to that of the color buffers.

Errors

    INVALID_OPERATION is generated if SampleCoverageARB is called
    between the execution of Begin and the execution of the
    corresponding End.

New State

Get Value	Get Command	Type	Initial Value	Attribute
MULTISAMPLE_ARB	IsEnabled	B	TRUE	multisample/enable
SAMPLE_ALPHA_TO_COVERAGE_ARB	IsEnabled	B	FALSE	multisample/enable
SAMPLE_ALPHA_TO_ONE_ARB	IsEnabled	B	FALSE	multisample/enable
SAMPLE_COVERAGE_ARB	IsEnabled	B	FALSE	multisample/enable
SAMPLE_COVERAGE_VALUE_ARB	GetFloatv	R+	1	multisample
SAMPLE_COVERAGE_INVERT_ARB	GetBooleanv	B	FALSE	multisample

Revision History

```
    09/20/1999  0.1
        - First ARB draft based on the original SGI draft.

    10/1/1999   0.2
        - Added query for the number of passes.

    11/8/1999   0.3
        - Fixed numerous typos reported by E&S.

    12/7/1999   0.4
        - Removed the multiple pass feature.
        - Resolved the working group issues at the ARB meeting.
        - Added language that stated that SAMPLE_BUFFERS_ARB is the
          same value as either GLX_SAMPLE_BUFFERS_ARB or
          WGL_SAMPLE_BUFFERS_ARB.

    12/15/1999  0.5
        - Added back in the statement about ALL_ATTRIB_BITS not
          including MULTISAMPLE_BIT_ARB.
```

Number

ARB Extension #29

Dependencies

Written based on the wording of the OpenGL 1.4 specification.

HP_occlusion_test affects the definition of this extension.

Overview

This extension defines a mechanism whereby an application can query the number of pixels (or, more precisely, samples) drawn by a primitive or group of primitives.

The primary purpose of such a query (hereafter referred to as an "occlusion query") is to determine the visibility of an object. Typically, the application will render the major occluders in the scene, then perform an occlusion query for the bounding box of each detail object in the scene. Only if said bounding box is visible, i.e., if at least one sample is drawn, should the corresponding object be drawn.

```
    The earlier HP_occlusion_test extension defined a similar mechanism,
    but it had two major shortcomings.

    - It returned the result as a simple GL_TRUE/GL_FALSE result, when in
      fact it is often useful to know exactly how many samples were
      drawn.

    - It provided only a simple "stop-and-wait" model for using multiple
      queries.  The application begins an occlusion test and ends it;
      then, at some later point, it asks for the result, at which point
      the driver must stop and wait until the result from the previous
      test is back before the application can even begin the next one.
      This is a very simple model, but its performance is mediocre when
      an application wishes to perform many queries, and it eliminates
      most of the opportunities for parallelism between the CPU and GPU.

    This extension solves both of those problems.  It returns as its
    result the number of samples that pass the depth and stencil tests,
    and it encapsulates occlusion queries in "query objects" that allow
    applications to issue many queries before asking for the result of
    any one.  As a result, they can overlap the time it takes for the
    occlusion query results to be returned with other, more useful work,
    such as rendering other parts of the scene or performing other
    computations on the CPU.

    There are many situations where a pixel/sample count, rather than a
    boolean result, is useful.

    - Objects that are visible but cover only a very small number of
      pixels can be skipped at a minimal reduction of image quality.

    - Knowing exactly how many pixels an object might cover may help the
      application decide which level-of-detail model should be used.  If
      only a few pixels are visible, a low-detail model may be
      acceptable.

    - "Depth peeling" techniques, such as order-independent transparency,
      need to know when to stop rendering more layers; it is difficult to
      determine a priori how many layers are needed.  A boolean result
      allows applications to stop when more layers will not affect the
      image at all, but this will likely result in unacceptable
      performance.  Instead, it makes more sense to stop rendering when
      the number of pixels in each layer falls below a given threshold.

    - Occlusion queries can replace glReadPixels of the depth buffer to
      determine whether (for example) a light source is visible for the
      purposes of a lens flare effect or a halo to simulate glare.  Pixel
      counts allow you to compute the percentage of the light source that
      is visible, and the brightness of these effects can be modulated
      accordingly.
```

Issues

How is this extension different from NV_occlusion_query?

The following changes have been made.

- A "target" parameter has been added. Only one target exists at present, SAMPLES_PASSED_ARB, but future extensions could add additional types of queries.
- Terminology changed slightly. "Pixel" was being used incorrectly, where "fragment" or "sample" would be more accurate.
- Various NVIDIA-specific references have been removed.
- Interactions with multisample have been changed slightly to allow implementations based on either a sample count or a fragment count. The result is returned in units of samples.
- Clarified that using an id of zero is illegal.
- Added missing spec language for IsQuery entry point.
- General language, issues, etc. cleanup.
- HP_occlusion_test is no longer required.
- Modified the minimum required counter bits to be dependent on the implementation's maximum viewport or the value 0
- Clarified that active query state is per target server state. This implies that a loop of QUERY_RESULT_AVAILABLE_ARB will return TRUE in finite time. NV_occlusion_query asked that the application flush to prevent an infinite loop.
- Clarified the behavior of the async QUERY_RESULT_AVAILABLE_ARB command.
- When the count of samples that pass the occlusion query overflows, the value should saturate.

Should we use an object-based interface?

RESOLVED: Yes, this makes the interface much simpler, and it is friendly for indirect rendering.

What is the difference between a "query object" and an "occlusion query"?

"Occlusion query" is a synonym for "query object used with target SAMPLES_PASSED".

Should we offer a way to poll whether an occlusion query has completed and its result is available?

RESOLVED. Yes, this allows applications to use CPU time that might have been spent spinning more usefully. However, the polling method introduced in the NV_occlusion_query spec allowed for a potential infinite loop if the application does not do a flush. This version of the spec clarifies the behavior which now makes such a flush unnecessary.

Is GetQueryObjectuivARB necessary?

RESOLVED: Yes, it makes using a 32-bit count less painful.

Should there be a limit on how many queries can be outstanding?

RESOLVED: No. This would make the extension much more difficult to spec and use. Allowing this does not add any significant implementation burden; and even if drivers have some internal limit on the number of outstanding queries, it is not expected that applications will need to know this to achieve optimal or near-optimal performance.

What happens if BeginQueryARB is called when a query is already outstanding for a different object on the same target?

RESOLVED: This is an INVALID_OPERATION error.

What happens if BeginQueryARB is called with an ID of a query that is already in progress?

RESOLVED: This is also an INVALID_OPERATION error.

What parameters should EndQueryARB have?

RESOLVED: Just a target. It doesn't need to take an "id" argument, since this would be redundant -- only one query can be active for any given target at a given time.

How many bits should we require the samples-passed count to be, at minimum?

RESOLVED. The largest minimum that can be required of a GL implementation is 32, the minimum bit width of an int or uint.

The minimum number of bits required for the samples-passed count will be dependent on the implementation's maximum viewport size. In order to allow for two overdraws in the case of only one sample buffer, the minimum counter precision (n) will be determined by:

```
n = min (32 , ceil (log2 (maxViewportWidth x maxViewportHeight x
                1 sample x 2 overdraws) ) )
```

An implementation can either set QUERY_COUNTER_BITS_ARB to the value 0, or to some number greater than or equal to n. If an implementation returns 0 for QUERY_COUNTER_BITS_ARB, then the occlusion queries will always return that zero samples passed the occlusion test, and so an application should not use occlusion queries on that implementation.

Note that other targets may come along in the future that require more or fewer bits.

What should we do about overflows?

RESOLVED: Overflows are required to saturate, though it is expected that several current implementations will not conform to this requirement.

The ideal behavior is to saturate. This ensures that you always get a "large" result when you render many samples. It also ensures that apps which want a boolean test can do this without worrying about the rare case where the result ends up exactly at zero after wrapping.

Either way, it's unlikely that this matters much as long as a sufficient number of bits are required.

What is the interaction with multisample?

RESOLVED: We count samples, not pixels -- even if MULTISAMPLE is disabled but SAMPLE_BUFFERS is 1.

A given fragment may have anywhere between zero and SAMPLES of its samples covered. Ideally, the samples-passed count would be incremented by the precise number of samples, but we permit implementations to instead increment the samples-passed count by SAMPLES if at least one sample in a given fragment is covered.

Note that the depth/stencil test optimization whereby implementations may choose to depth test at only one of the samples when MULTISAMPLE is disabled does not cause this to become ill-specified, because we are counting the number of samples that are still alive _after_ the depth test stage. The particular mechanism used to decide whether to kill or keep those samples is not relevant.

Exactly what stage in the pipeline are we counting samples at?

RESOLVED: We are counting immediately after _both_ the depth and stencil tests, i.e., samples that pass both. Note that the depth test comes after the stencil test, so to say that it is the number that pass the depth test is sufficient; though it is often conceptually helpful to think of the depth and stencil tests as being combined, because the depth test's result impacts the stencil operation used.

Is it guaranteed that occlusion queries return in order?

RESOLVED: Yes. It makes sense to do this. If occlusion test X occurred before occlusion query Y, and the driver informs the app that occlusion query Y is done, the app can infer that occlusion query X is also done. For applications that do poll, this allows them to do so with less effort.

Will polling a query without a Flush possibly cause an infinite loop?

RESOLVED: No. An infinite loop was possible in the original NV_occlusion_query spec if an application did not perform a flush prior to polling. This behavior was removed in this version of the spec as it violated language in the core GL spec.

Instead of allowing for an infinite loop, performing a QUERY_RESULT_AVAILABLE_ARB will perform a flush if the result is not ready yet on the first time it is queried. This ensures that the async query will return true in finite time.

This behavior is not a significant performance loss over the original version of the spec. A flush would need to be performed at some point anyway and the flush performed when QUERY_RESULT_AVAILABLE_ARB is requested will only occur *if the result is not back yet*.

What should be the interaction between this spec and HP_occlusion_test?

RESOLVED: Whereas NV_occlusion_query required that you implement HP_occlusion_test, and even went so far as to specify the precise behavior of HP_occlusion_test (since the HP_occlusion_test spec did not contain those details), this spec does not. This spec explains the interaction with HP_occlusion_test, but does not attempt to double as a spec for that extension.

What happens if HP_occlusion_test and ARB_occlusion_query usage is overlapped?

RESOLVED: The two can be overlapped safely. Counting is enabled if either an occlusion query is active *or* OCCLUSION_TEST_HP is enabled. The alternative (producing an error) does not work -- it would require that PopAttrib be capable of producing an error, which would be rather problematic.

Note that BeginQueryARB, not EndQueryARB, resets the sample count (and therefore the occlusion test result). This can avoid certain types of strange behavior where an occlusion query's samples-passed count does not always correspond to the samples rendered during the occlusion query. The spec would make sense the other way, but the behavior would be strange.

Should there be a "target" parameter to BeginQueryARB?

RESOLVED: Yes. Whereas NV_occlusion_query wasn't trying to solve a problem beyond simple occlusion queries, this extension creates a framework useful for future queries.

Does GenQueriesARB need a "target" parameter?

RESOLVED: No. A query can be reused any number of times with any targets.

How can one ask for the currently active query?

RESOLVED: A new entry point has been added to query information about a given query target. This makes it unnecessary to add two new enumerants (# of bits and current query ID) for each new target that is introduced.

Are query objects shareable between multiple contexts?

RESOLVED: No. Query objects are lightweight and we normally share large data across contexts. Also, being able to share query objects across contexts is not particularly useful. In order to do the async query across contexts, a query on one context would have to be finished before the other context could query it.

What happens when an app begins a query on a target, ends it, begins a query on the same target with the same id, ends it, and then tries to retrieve data about the query using GetQueryObjecti[u]vARB? Which query does the GetQueryObjecti[u]vARB return results for?

RESOLVED. In this case, the result retrieved from GetQueryObjecti[u]vARB will be from the last query on that target and id. The result returned from GetQueryObjecti[u]vARB will always be from the last BeginQueryARB/EndQueryARB pair on that target and id.

Is this extension useful for saving geometry, fill rate, or both?

The answer to this question is to some extent implementation-dependent, but it is expected that it is most useful for reducing geometry workload, and less so for fill rate.

For the cost of rendering a bounding box, you can potentially save rendering a normal object. A bounding box consists of only 12 triangles, whereas the original object might have contained thousands or even millions of triangles.

Using bounding box occlusion queries may either help or hurt in fill-limited situations, because rendering the pixels of a bounding box is not free. In most situations, a bounding box will probably have more pixels than the original object. Those pixels can probably be rendered more quickly, though, since they involve only Z reads (no Z writes or color traffic), and they need not be textured or otherwise shaded.

In multipass rendering situations, however, occlusion queries can almost always save fill rate, because wrapping an object with an occlusion query is generally cheap. See "Usage Examples" for an illustration.

What can be said about guaranteeing correctness when using occlusion queries, especially as it relates to invariance?

Invariance is critical to guarantee the correctness of occlusion queries. If occlusion queries go through a different code path than standard rendering, the fragments rendered may be different.

However, the invariance issues are difficult at best to solve. Because of the vagaries of floating-point precision, it is difficult to guarantee that rendering a bounding box will render at least as many pixels with equal or smaller Z values than the object itself would have rendered.

Likewise, many other aspects of rendering state tend to be different when performing an occlusion query. Color and depth writes are typically disabled, as are texturing, vertex programs, and any fancy per-fragment math. So unless all these features have guarantees of invariance themselves (unlikely at best), requiring invariance for ARB_occlusion_query would be futile.

In general, implementations are recommended to be fully invariant with respect to whether any given type of query is active, insofar as it is possible. That is, having an occlusion query active should not affect the operation of any other stage of the pipeline. Following this rule is essential to numerous occlusion query algorithms working correctly. However, to permit implementations where this feature is implemented in software, this rule is only a recommendation, not a requirement.

Another unrelated problem that can threaten correctness is near and far clipping. The bounding box of an object may penetrate the near clip plane, even though the original object may not have. In such a circumstance, a bounding box occlusion query may produce an incorrect result. Whenever you design an algorithm using occlusion queries, it is best to be careful about the near and far clip planes.

How can frame-to-frame coherency help applications using this extension get even higher performance?

Usually, if an object is visible one frame, it will be visible the next frame, and if it is not visible, it will not be visible the next frame.

Of course, for most applications, "usually" isn't good enough. It is undesirable, but acceptable, to render an object that *isn't* visible, because that only costs performance. It is generally unacceptable to *not* render an object that *is* visible.

The simplest approach is that visible objects should be checked every N frames (where, say, N=5) to see if they have become occluded, while objects that were occluded last frame must be rechecked again in the current frame to guarantee that they are still occluded. This will reduce the number of wasteful occlusion queries by almost a factor of N.

Other, more complicated techniques exist but are beyond the scope of this extension document.

Do occlusion queries make other visibility algorithms obsolete?

No.

Occlusion queries are helpful, but they are not a cure-all. They should be only one of many items in your bag of tricks to decide whether objects are visible or invisible. They are not an excuse to skip frustum culling, or precomputing visibility using portals for static environments, or other standard visibility techniques.

New Procedures and Functions

```
    void GenQueriesARB(sizei n, uint *ids);
    void DeleteQueriesARB(sizei n, const uint *ids);
    boolean IsQueryARB(uint id);
    void BeginQueryARB(enum target, uint id);
    void EndQueryARB(enum target);
    void GetQueryivARB(enum target, enum pname, int *params);
    void GetQueryObjectivARB(uint id, enum pname, int *params);
    void GetQueryObjectuivARB(uint id, enum pname, uint *params);
```

New Tokens

Accepted by the <target> parameter of BeginQueryARB, EndQueryARB, and GetQueryivARB:

```
        SAMPLES_PASSED_ARB                            0x8914
```

Accepted by the <pname> parameter of GetQueryivARB:

```
        QUERY_COUNTER_BITS_ARB                        0x8864
        CURRENT_QUERY_ARB                             0x8865
```

Accepted by the <pname> parameter of GetQueryObjectivARB and GetQueryObjectuivARB:

```
        QUERY_RESULT_ARB                              0x8866
        QUERY_RESULT_AVAILABLE_ARB                    0x8867
```

Additions to Chapter 2 of the OpenGL 1.4 Specification (OpenGL Operation)

Modify Section 2.1, OpenGL Fundamentals (p. 4)

(modify fourth paragraph, p. 4) It also means that queries and pixel read operations return state consistent with complete execution of all previously invoked GL commands, except where explicitly specified otherwise

Additions to Chapter 3 of the OpenGL 1.4 Specification (Rasterization)

None.

Additions to Chapter 4 of the OpenGL 1.4 Specification (Per-Fragment Operations and the Frame Buffer)

Add a new section "Occlusion Queries" between sections 4.1.6 and 4.1.7:

"4.1.6A Occlusion Queries

Occlusion queries can be used to track the number of fragments or samples that pass the depth test.

Occlusion queries are associated with query objects. The command

```
  void GenQueriesARB(sizei n, uint *ids);
```

returns <n> previously unused query object names in <ids>. These names are marked as used, but no object is associated with them until the first time they are used by BeginQueryARB. Query objects contain one piece of state, an integer result value. This result value is initialized to zero when the object is created. Any positive integer except for zero (which is reserved for the GL) is a valid query object name.

Query objects are deleted by calling

```
  void DeleteQueriesARB(sizei n, const uint *ids);
```

<ids> contains <n> names of query objects to be deleted. After a query object is deleted, its name is again unused. Unused names in <ids> are silently ignored.

An occlusion query can be started and finished by calling

```
  void BeginQueryARB(enum target, uint id);
  void EndQueryARB(enum target);
```

where <target> is SAMPLES_PASSED_ARB. If BeginQueryARB is called with an unused <id>, that name is marked as used and associated with a new query object. If BeginQueryARB is called while another query is already in progress with the same target, an INVALID_OPERATION error is generated. If EndQueryARB is called while no query with the same target is in progress, an INVALID_OPERATION error is generated. Calling either GenQueriesARB or DeleteQueriesARB while any query of any target is active causes an INVALID_OPERATION error to be generated.

BeginQueryARB with a <target> of SAMPLES_PASSED_ARB resets the current samples-passed count to zero and sets the query active state to TRUE and the active query id to <id>. EndQueryARB with a target of SAMPLES_PASSED_ARB initializes a copy of the current samples-passed count into the active occlusion query object's results value, sets the active occlusion query object's result available to FALSE, sets the query active state to FALSE, and the active query id to 0.

If BeginQueryARB is called with an <id> of zero, or where <id> is the name of a query currently in progress, an INVALID_OPERATION error is generated.

When an occlusion query is active, the samples-passed count increases by a certain quantity for each fragment that passes the depth test. If the value of SAMPLE_BUFFERS is 0, then the samples-passed count increases by 1 for each fragment. If the value of SAMPLE_BUFFERS is 1, then the samples-passed count increases by the number of samples whose coverage bit is set. However, implementations, at their discretion, are allowed to instead increase the samples-passed count by the value of SAMPLES if any sample in the fragment is covered.

If the samples-passed count overflows, i.e., exceeds the value 2^n-1 (where n is the number of bits in the samples-passed count), its value becomes undefined. It is recommended, but not required, that implementations handle this overflow case by saturating at 2^n-1 and incrementing no further.

The necessary state is a single bit indicating whether an occlusion query is active, the identifier of the currently active occlusion query, and a counter keeping track of the number of samples that have passed."

Additions to Chapter 5 of the OpenGL 1.4 Specification (Special Functions)

Add to the end of Section 5.4 "Display Lists":

"DeleteQueriesARB, GenQueriesARB, IsQueryARB, GetQueryivARB, GetQueryObjectivARB, and GetQueryObjectuivARB are not compiled into display lists but are executed immediately."

Additions to Chapter 6 of the OpenGL 1.4 Specification (State and State Requests)

Add a new section 6.1.13 "Occlusion Queries":

"The command

```
  boolean IsQueryARB(uint id);
```

returns TRUE if <id> is the name of a query object. If <id> is zero, or if <id> is a non-zero value that is not the name of a query object, IsQueryARB returns FALSE.

Information about a query target can be queried with the command

```
  void GetQueryivARB(enum target, enum pname, int *params);
```

If <pname> is CURRENT_QUERY_ARB, the name of the currently active query for <target>, or zero if no query is active, will be placed in <params>.

If <pname> is QUERY_COUNTER_BITS_ARB, the number of bits in the counter for <target> will be placed in <params>. The minimum number of query counter bits allowed is a function of the implementation's maximum viewport dimensions (MAX_VIEWPORT_DIMS). If the counter is non-zero, then the counter must be able to represent at least two overdraws for every pixel in the viewport using only one sample buffer. The formula to compute the allowable minimum value is below (where n is the minimum number of bits):

```
  n = (min (32, ceil (log2 (maxViewportWidth x maxViewportHeight x 2) ) ) )
       or 0
```

If the value of n is 0, then the result from GetQueryiv(SAMPLES_PASSED_ARB) will always return 0,

```
    The state of a query object can be queried with the commands

      void GetQueryObjectivARB(uint id, enum pname, int *params);
      void GetQueryObjectuivARB(uint id, enum pname, uint *params);

    If <id> is not the name of a query object, or if the query object
    named by <id> is currently active, then an INVALID_OPERATION error is
    generated.

    If <pname> is QUERY_RESULT_ARB, then the query object's result value
    is placed in <params>.

    Often, query object results will be returned asynchronously with
    respect to the host processor's operation.  As a result, sometimes,
    if a result is queried, the host must wait until the result is back.
    If <pname> is QUERY_RESULT_AVAILABLE_ARB, the value placed in <params>
    indicates whether or not such a wait would occur if the result of
    that query object were to be queried presently.  A result of TRUE
    means no wait would be required; a result of FALSE means that some
    wait would occur.  It must always be true that if the result for
    one query is available, the result for all previous queries must
    also be available at that point in time.

    Querying the state for a given occlusion query forces that occlusion
    query to complete within a finite amount of time.

    If multiple queries are issued on the same target and id prior to
    calling GetQueryObject[u]iVARB, the result returned will always be
    from the last query issued.  The results from any queries before
    the last one will be lost if the results are not retrieved before
    starting a new query on the same target and id."
```

Dependencies on HP_occlusion_test

```
    When GetIntegerv is called with <pname> of OCCLUSION_TEST_RESULT_HP,
    the current samples-passed count is reset to zero.  The occlusion
    test result is TRUE when the samples-passed count is nonzero, and
    FALSE when it is zero.  Sample counting is active (i.e. the samples-
    passed count increases as fragments are drawn) whenever either an
    occlusion query is active *or* OCCLUSION_TEST_HP is enabled.
```

GLX Protocol

```
    Seven new GL commands are added.

    The following two rendering commands are sent to the server as part
    of a glXRender request:

        BeginQueryARB
            2           12              rendering command length
            2           ????            rendering command opcode
            4           ENUM            target
            4           CARD32          id
        EndQueryARB
            2           8               rendering command length
            2           ????            rendering command opcode
            4           ENUM            target

    The remaining fivecommands are non-rendering commands.  These
    commands are sent separately (i.e., not as part of a glXRender or
    glXRenderLarge request), using the glXVendorPrivateWithReply
    request:

        DeleteQueriesARB
            1           CARD8           opcode (X assigned)
            1           17              GLX opcode (glXVendorPrivateWithReply)
            2           4+n             request length
            4           ????            vendor specific opcode
            4           GLX_CONTEXT_TAG context tag
            4           INT32           n
            n*4         LISTofCARD32    ids

        GenQueriesARB
            1           CARD8           opcode (X assigned)
            1           17              GLX opcode (glXVendorPrivateWithReply)
            2           4               request length
            4           ????            vendor specific opcode
            4           GLX_CONTEXT_TAG context tag
            4           INT32           n
          =>
            1           1               reply
            1                           unused
            2           CARD16          sequence number
            4           n               reply length
            24                          unused
            n*4         LISTofCARD322   queries

        IsQueryARB
            1           CARD8           opcode (X assigned)
            1           17              GLX opcode (glXVendorPrivateWithReply)
            2           4               request length
            4           ????            vendor specific opcode
            4           GLX_CONTEXT_TAG context tag
            4           CARD32          id
          =>
            1           1               reply
            1                           unused
            2           CARD16          sequence number
            4           0               reply length
            4           BOOL32          return value
            20                          unused
            1           1               reply
        GetQueryivARB
            1           CARD8           opcode (X assigned)
            1           17              GLX opcode (glXVendorPrivateWithReply)
            2           5               request length
            4           ????            vendor specific opcode
            4           GLX_CONTEXT_TAG context tag
            4           ENUM            target
            4           ENUM            pname
          =>
            1           1               reply
            1                           unused
            2           CARD16          sequence number
            4           m               reply length, m=(n==1?0:n)
            4                           unused
            4           CARD32          n

            if (n=1) this follows:

            4           INT32           params
            12                          unused

            otherwise this follows:

            16                          unused
            n*4         LISTofINT32     params

        GetQueryObjectivARB
            1           CARD8           opcode (X assigned)
            1           17              GLX opcode (glXVendorPrivateWithReply)
            2           5               request length
            4           ????            vendor specific opcode
            4           GLX_CONTEXT_TAG context tag
            4           CARD32          id
            4           ENUM            pname
          =>
            1           1               reply
            1                           unused
            2           CARD16          sequence number
            4           m               reply length, m=(n==1?0:n)
            4                           unused
            4           CARD32          n

            if (n=1) this follows:

            4           INT32           params
            12                          unused

            otherwise this follows:

            16                          unused
            n*4         LISTofINT32     params
        GetQueryObjectuivARB
            1           CARD8           opcode (X assigned)
            1           17              GLX opcode (glXVendorPrivateWithReply)
            2           5               request length
            4           ????            vendor specific opcode
            4           GLX_CONTEXT_TAG context tag
            4           CARD32          id
            4           ENUM            pname
          =>
            1           1               reply
            1                           unused
            2           CARD16          sequence number
            4           m               reply length, m=(n==1?0:n)
            4                           unused
            4           CARD32          n

            if (n=1) this follows:

            4           CARD32          params
            12                          unused

            otherwise this follows:

            16                          unused
            n*4         LISTofCARD32    params
```

Errors

```
    The error INVALID_VALUE is generated if GenQueriesARB is called where
    <n> is negative.

    The error INVALID_VALUE is generated if DeleteQueriesARB is called
    where <n> is negative.

    The error INVALID_OPERATION is generated if GenQueriesARB or
    DeleteQueriesARB is called when a query of any target is active.

    The error INVALID_ENUM is generated if BeginQueryARB, EndQueryARB, or
    GetQueryivARB is called where <target> is not SAMPLES_PASSED_ARB.

    The error INVALID_OPERATION is generated if BeginQueryARB is called
    when a query of the given <target> is already active.

    The error INVALID_OPERATION is generated if EndQueryARB is called
    when a query of the given <target> is not active.

    The error INVALID_OPERATION is generated if BeginQueryARB is called
    where <id> is zero.

    The error INVALID_OPERATION is generated if BeginQueryARB is called
    where <id> is is the name of a query currently in progress.

    The error INVALID_ENUM is generated if GetQueryivARB is called where
    <pname> is not QUERY_COUNTER_BITS_ARB or CURRENT_QUERY_ARB.
```

    The error INVALID_OPERATION is generated if GetQueryObjectivARB or
    GetQueryObjectuivARB is called where <id> is not the name of a query
    object.

    The error INVALID_OPERATION is generated if GetQueryObjectivARB or
    GetQueryObjectuivARB is called where <id> is the name of a currently
    active query object.

    The error INVALID_ENUM is generated if GetQueryObjectivARB or
    GetQueryObjectuivARB is called where <pname> is not QUERY_RESULT_ARB
    or QUERY_RESULT_AVAILABLE_ARB.

    The error INVALID_OPERATION is generated if any of the commands
    defined in this extension is executed between the execution of Begin
    and the corresponding execution of End.

New State

Usage Examples

Here is some rough sample code that illustrates how this extension can be used.

```
GLuint queries[N];
GLuint sampleCount;
GLint available;
GLuint bitsSupported;

// check to make sure functionality is supported
glGetQueryiv(GL_QUERY_COUNTER_BITS_ARB, &bitsSupported);
if (bitsSupported == 0) {
    // render scene without using occlusion queries
}

glGenQueriesARB(N, queries);
...
// before this point, render major occluders
glColorMask(GL_FALSE, GL_FALSE, GL_FALSE, GL_FALSE);
glDepthMask(GL_FALSE);
// also disable texturing and any fancy shaders
for (i = 0; i < N; i++) {
    glBeginQueryARB(GL_SAMPLES_PASSED_ARB, queries[i]);
    // render bounding box for object i
    glEndQueryARB(GL_SAMPLES_PASSED_ARB);
}

glFlush();

// Do other work until "most" of the queries are back, to avoid
// wasting time spinning
i = N*3/4; // instead of N-1, to prevent the GPU from going idle
do {
    DoSomeStuff();
    glGetQueryObjectivARB(queries[i],
                          GL_QUERY_RESULT_AVAILABLE_ARB,
                          &available);
} while (!available);

glColorMask(GL_TRUE, GL_TRUE, GL_TRUE, GL_TRUE);
glDepthMask(GL_TRUE);
// reenable other state, such as texturing
for (i = 0; i < N; i++) {
    glGetQueryObjectuivARB(queries[i], GL_QUERY_RESULT_ARB,
                           &sampleCount);
    if (sampleCount > 0) {
        // render object i
    }
}
```

Here is some rough sample code for a simple multipass rendering application that does not use occlusion queries.

```
    for (i = 0; i < N; i++) {
        // First rendering pass
        glDisable(GL_BLEND);
        glDepthFunc(GL_LESS);
        glDepthMask(GL_TRUE);
        // configure shader 0
        // render object i

        // Second rendering pass
        glEnable(GL_BLEND);
        glBlendFunc(...);
        glDepthFunc(GL_EQUAL);
        glDepthMask(GL_FALSE);
        // configure shader 1
        // render object i
    }
```

Here is the previous example, enhanced using occlusion queries.

```
    GLuint queries[N];
    GLuint sampleCount;

    glGenQueriesARB(N, queries);
    ...
    // First rendering pass plus almost-free visibility checks
    glDisable(GL_BLEND);
    glDepthFunc(GL_LESS);
    glDepthMask(GL_TRUE);
    // configure shader 0
    for (i = 0; i < N; i++) {
        glBeginQueryARB(GL_SAMPLES_PASSED_ARB, queries[i]);
        // render object i
        glEndQueryARB(GL_SAMPLES_PASSED_ARB);
    }

    // Second pass only on objects that were visible
    glEnable(GL_BLEND);
    glBlendFunc(...);
    glDepthFunc(GL_EQUAL);
    glDepthMask(GL_FALSE);
    // configure shader 1
    for (i = 0; i < N; i++) {
        glGetQueryObjectuivARB(queries[i], GL_QUERY_RESULT_ARB,
                               &sampleCount);
        if (sampleCount > 0) {
            // render object i
        }
    }
```

Name

    ARB_pixel_buffer_object

Name Strings

    GL_ARB_pixel_buffer_object

Status

    Complete. Approved by ARB on December 7, 2004.

Version

    Last Modified Date: December 8, 2004
    Revision: 1.0

Number

    ARB Extension #42

Dependencies

    Written based on the wording of the OpenGL 2.0 specification.

    Assumes support for (at least) OpenGL 1.5 or the
    ARB_vertex_buffer_object extension.

    NV_pixel_data_range affects the definition of this extension.

    EXT_pixel_buffer_object interacts with this extension.

Overview

This extension expands on the interface provided by the ARB_vertex_buffer_object extension (and later integrated into OpenGL 1.5) in order to permit buffer objects to be used not only with vertex array data, but also with pixel data. The intent is to provide more acceleration opportunities for OpenGL pixel commands.

While a single buffer object can be bound for both vertex arrays and pixel commands, we use the designations vertex buffer object (VBO) and pixel buffer object (PBO) to indicate their particular usage in a given situation.

Recall that buffer objects conceptually are nothing more than arrays of bytes, just like any chunk of memory. ARB_vertex_buffer_object allows GL commands to source data from a buffer object by binding the buffer object to a given target and then overloading a certain set of GL commands' pointer arguments to refer to offsets inside the buffer, rather than pointers to user memory. An offset is encoded in a pointer by adding the offset to a null pointer.

This extension does not add any new functionality to buffer objects themselves. It simply adds two new targets to which buffer objects can be bound: GL_PIXEL_PACK_BUFFER and GL_PIXEL_UNPACK_BUFFER. When a buffer object is bound to the GL_PIXEL_PACK_BUFFER target, commands such as glReadPixels pack (write) their data into a buffer object. When a buffer object is bound to the GL_PIXEL_UNPACK_BUFFER target, commands such as glDrawPixels and glTexImage2D unpack (read) their data from a buffer object.

There are a several approaches to improve graphics performance with PBOs. Some of the most interesting approaches are:

- Streaming texture updates: If the application uses glMapBuffer/glUnmapBuffer to write its data for glTexSubImage into a buffer object, at least one of the data copies usually required to download a texture can be eliminated, significantly increasing texture download performance.

- Streaming draw pixels: When glDrawPixels sources client memory, OpenGL says the client memory can be modified immediately after the glDrawPixels command returns without disturbing the drawn image. This typically necessitates unpacking and copying the image prior to glDrawPixels returning. However, when using glDrawPixels with a pixel pack buffer object, glDrawPixels may return prior to image unpacking because future modification of the buffer data requires explicit commands (glMapBuffer, glBufferData, or glBufferSubData).

- Asynchronous glReadPixels: If an application needs to read back a number of images and process them with the CPU, the existing GL interface makes it nearly impossible to pipeline this operation. The driver will typically send the hardware a readback command when glReadPixels is called, and then wait for all of the data to be available before returning control to the application. Then, the application can either process the data immediately or call glReadPixels again; in neither case will the readback overlap with the processing. If the application issues several readbacks into several buffer objects, however, and then maps each one to process its data, then the readbacks can proceed in parallel with the data processing.

- Render to vertex array: The application can use a fragment program to render some image into one of its buffers, then read this image out into a buffer object via glReadPixels. Then, it can use this buffer object as a source of vertex data.

Issues

1) *How does this extension relate to ARB_vertex_buffer_object?*

It builds on the ARB_vertex_buffer_object framework by adding two new targets that buffers can be bound to.

2) *How does this extension relate to NV_pixel_data_range?*

This extension relates to NV_pixel_data_range in the same way that ARB_vertex_buffer_object relates to NV_vertex_array_range. To paraphrase the ARB_vertex_buffer_object spec, here are the main differences:

- Applications are no longer responsible for memory management and synchronization.

- Applications may still access high-performance memory directly, but this is optional, and such access is more restricted.

- Buffer changes (glBindBuffer) are generally expected to be very lightweight, rather than extremely heavyweight (glPixelDataRangeNV).

- A platform-specific allocator such as wgl/glXAllocateMemoryNV is no longer required.

3) *Can a given buffer be used for both vertex and pixel data?*

RESOLVED: YES. All buffers can be used with all buffer bindings, in whatever combinations the application finds useful. Consider yourself warned, however, by the following issue.

4) *May implementations make use of the target as a hint to select an appropriate memory space for the buffer?*

RESOLVED: YES, as long as such behavior is transparent to the application. Some implementations may choose, for example, that they would rather stream vertex data from AGP memory, element (index) data from video memory, and pixel data from video memory. In fact, one can imagine arbitrarily complicated heuristics for selecting the memory space, based on factors such as the target, the "usage" argument, and the application's observed behavior.

While it is entirely legal to create a buffer object by binding it to GL_ARRAY_BUFFER and loading it with data, then using it with the GL_PIXEL_UNPACK_BUFFER_ARB or GL_PIXEL_PACK_BUFFER_ARB binding, such behavior is liable to confuse the driver and may hurt performance. If the driver implemented the hypothetical heuristic described earlier, such a buffer might have already been located in AGP memory, and so the driver would have to choose between two bad options: relocate the buffer into video memory, or accept lower performance caused by streaming pixel data from AGP.

5) *Should all pixel path commands be supported, or just a subset of them?*

RESOLVED: ALL. While there is little reason to believe that, say, glConvolutionFilter2D would benefit from this extension, there is no reason _not_ to support it. The complete list of commands affected by this extension is listed in issues 17 and 18.

6) *Should glPixelMap and glGetPixelMap be supported?*

RESOLVED: YES. They're not really pixel path operations, but, again, there is no good reason to omit operations, and they _are_ operations that pass around big chunks of pixel-related data. If we support glPolygonStipple, surely we should support this.

7) *How does the buffer binding state push/pop?*

RESOLVED: As part of the pixel store client state. This is analogous to how the ARB_vertex_buffer_object bindings pushed/popped as part of the vertex array client state.

8) *Should NV_pixel_data_range (PDR) be used concurrently with pixel buffer objects ?*

RESOLVED: NO. While it would be possible to allocate a memory range for PDR, using a pointer into this memory range with one of the commands affected by PBOs will not work if a pixel buffer object other than zero is bound to the buffer binding point affecting the command.

Pixel buffer objects always have higher precedence than PDR.

9) *Should the INVALID_OPERATION error be generated if a pixel command would access data outside the range of the bound PBO?*

RESOLVED: YES. This requires considering the command parameters (such as width/height/depth/format/type/pointer), the current pixel store (pack/unpack) state, and the command operation itself to determine the maximum addressed byte for the pixel command.

Brian Paul strongly recommends this behavior.

This behavior should increase the reliability of using PBO and guard against programmer mistakes.

This is particularly important for glReadPixels where returning data into a region outside the PBO could cause corruption of application memory.

Such bounds checking is substantially more expensive for VBO accesses because bounds checking on a per-vertex element basis for each of multiple enabled vertex arrays prior to performing the command compromises the performance justification of VBO.

10) *If a pixel command with a bound PBO accesses data outside the range of the PBO, thereby generating a GL_INVALID_OPERATION error, can the pixel command end up being partially processed?*

RESOLVED: NO. As for all GL errors excepting GL_OUT_OF_MEMORY situations, "the command generating the error is ignored so that it has no effect on GL state or framebuffer contents."

This means implementations must determine before the pixel command is performed whether the resulting read or write operations on the bound PBO will exceed the size of the PBO.

This means an implementation is NOT allowed to detect out of bounds accesses in the middle of performing the command.

11) *How expensive is it to predetermine whether a pixel command accessing a PBO would have an out of bounds access?*

See the "Appendix on Pack/Unpack Range" to see the computations involved in computing the access limit.

Implementations can further specialize and optimize the check to make this out of bounds checking negligible for any sizable pixel payload.

12) *Should feedback and select buffers output results into a buffer object?*

RESOLVED: That might be useful for a future extension but is not appropriate for this extension. New targets (other than PIXEL_PACK_BUFFER_ARB and PIXEL_UNPACK_BUFFER_ARB) make sense.

13) *Should NV_pixel_data_range interactions be documented in this specification?*

RESOLVED: YES. Interactions with NV_pixel_data_range are important to document to facilitate developers migrating to the multi-vendor ARB_pixel_buffer_object extension. Discussion of interactions is limited to the issues and example usage sections.

Other ARB specifications follow this policy, and Jon Leech agrees with this policy.

14) *Should an INVALID_OPERATION error be generated if the offset within a pixel buffer to a datum comprising of N basic machine units is not a multiple of N?*

RESOLVED: YES. This was stated for VBOs but no error was defined if the rule was violated. Perhaps this needs to be better specified for VBO.

For PBO, it is reasonable and cheap to enforce the alignment rule. For pixel commands it means making sure the offset is evenly divisible by the component or group size in basic machine units.

```
        This check is independent of the pixel store state because the
        pixel store state is specified in terms of pixels (not basic
        machine units) so pixel store addressing cannot create an
        unaligned access as long as the base offset is aligned.

        Certain commands (specifically glPolygonStipple,
        glGetPolygonStipple, glBitmap, glCompressedTexImage1D,
        glCompressedTexImage2D, glCompressedTexImage3D,
        glCompressedTexSubImage1D, glCompressedTexSubImage2D,
        glCompressedTexSubImage3D, and glGetCompressedTexImage) are not
        affected by this error because the data accessed is addressed
        at the granularity of basic machine units.

    15) Various commands do not make explicit reference to supporting
        packing or unpacking from a pixel buffer object but rather specify
        that parameters are handled in the same manner as glDrawPixels,
        glReadPixels, or the glCompressedTexImage commands.  So do such
        commands (example: glCompressedTexSubImage2D) use pixel buffers?

        RESOLVED:  YES.  Commands that have their behavior defined based
        on commands that read or write from pixel buffers will themselves
        read or write from pixel buffers.  Relying on this reduces the
        amount of specification language to be updated.

    16) What is the complete list of commands that can unpack (read)
        pixels from the current pixel unpack buffer object?

            glBitmap
            glColorSubTable
            glColorTable
            glCompressedTexImage1D
            glCompressedTexImage2D
            glCompressedTexImage3D
            glCompressedTexSubImage1D
            glCompressedTexSubImage2D
            glCompressedTexSubImage3D
            glConvolutionFilter1D
            glConvolutionFilter2D
            glDrawPixels
            glPixelMapfv
            glPixelMapuiv
            glPixelMapusv
            glPolygonStipple
            glSeparableFilter2D
            glTexImage1D
            glTexImage2D
            glTexImage3D
            glTexSubImage1D
            glTexSubImage2D
            glTexSubImage3D
    17) What is the complete list of commands that can pack (write)
        pixels into the current pixel pack buffer object?

            glGetCompressedTexImage
            glGetConvolutionFilter
            glGetHistogram
            glGetMinmax
            glGetPixelMapfv
            glGetPixelMapuiv
            glGetPixelMapusv
            glGetPolygonStipple
            glGetSeparableFilter,
            glGetTexImage
            glReadPixels

    18) How does support for pixel buffer objects affect the GLX protocol?

        UNRESOLVED:  See the "GLX Protocol" section.

    19) Prior to this extension, passing zero for the data argument of
        glTexImage1D, glTexImage2D, and glTexImage3D defined a texture
        image level without supplying an image.  How does this behavior
        change with this extension?

        RESOLVED:  The "unspecified image" behavior of the glTexImage
        calls only applies when bound to a zero pixel unpack buffer
        object.

        When bound to a non-zero pixel unpack buffer object, the data
        argument to these calls is treated as an offset rather than
        a pointer so zero is a reasonable and even likely value that
        corresponds to the very beginning of the buffer object's data.

        So to create a texture image level with unspecified image data,
        you MUST bind to the zero pixel unpack buffer object.

        See the ammended language at the end of section 3.8.1.

    20) How does this extension support video frame grabbers?

        RESOLVED:  This extension extends buffer objects so they can
        operate with pixel commands, rather than just vertex array
        commands.

        We anticipate that a future extension may provide a mechanism
        for transferring video frames from video frame grabber hardware
        or vertices from motion capture hardware (or any other source
        of aquired real-time data) directly into a buffer object to
        eliminate a copy.  Ideally, such transfers would be possible
        without requiring mapping of the buffer object.  But this
        extension does not provide such functionality.

        We anticipate such functionality to involve binding a buffer
        object to a new target type, configuring a source (or sink) for
        data (video frames, motion capture vertex sets, etc.), and then
        commands to initiate data transfers to the bound buffer object.
```

21) Can this ARB extension share the same enumerants with the EXT version of this functionality?

RESOLVED: YES. The ARB extension is functionally compatible with EXT_pixel_buffer_object except that the ARB version adds additional error checks for alignment and buffer bounds checking.

The EXT behavior in the case of alignment violations and buffer bounds overflow are technically undefined. The ARB extension simply defines the EXT extension's undefined behavior to be an OpenGL error.

Using the same enumerants with firmed up error checking (that would otherwise indicate buggy usage) is preferable to two sets of enumerants where the older EXT set simply allows sloppy usage.

22) The expected usage parameters (GL_STREAM_DRAW, etc.) for glBufferData are not clearly specified. How can they be improved?

RESOLVED: To improve the clarity, replace the phrase "specified once" with "specified once per repetition of the usage pattern" so that it is clear for the STREAM_* usage modes (and the STATIC_* usage modes too, just much less frequently) that the repeated specification is part of a pattern and it is expected that the buffer can be, and will be for the STREAM_* usage patterns, specified again after being used and this is likely to repeat.

Additionally, the *_COPY and *_DRAW usage patterns can source the data with "a GL drawing command" but also with image specification commands so change this phrase to "a GL drawing or image specification command."

23) Is this the "right" way to expose render-to-vertex-array?

DISCUSSION: You can use this extension to render an image into a framebuffer, copy the pixels into a buffer object with glReadPixels, and then configure vertex arrays to source the pixel data as vertex attributes. This necessarily involves a copy from the framebuffer to the buffer object. Future extensions may provide mechanisms for copy-free render-to-vertex-array capabilities but that is not a design goal of this extension.

New Procedures and Functions

None.

New Tokens

Accepted by the <target> parameters of BindBuffer, BufferData, BufferSubData, MapBuffer, UnmapBuffer, GetBufferSubData, GetBufferParameteriv, and GetBufferPointerv:

```
    PIXEL_PACK_BUFFER_ARB                       0x88EB
    PIXEL_UNPACK_BUFFER_ARB                     0x88EC
```

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
    PIXEL_PACK_BUFFER_BINDING_ARB               0x88ED
    PIXEL_UNPACK_BUFFER_BINDING_ARB             0x88EF
```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

None

-- Section 2.9 "Buffer Objects"

Replace the first two paragraphs with:

"The vertex data arrays described in section 2.8 are stored in client memory. It is sometimes desirable to store frequently accessed client data, such as vertex array and pixel data, in high-performance server memory. GL buffer objects provide a mechanism for clients to use to allocate, initialize, and access such memory."

The name space for buffer objects is the unsigned integer, with zero reserved for the GL. A buffer object is created by binding an unused name to a buffer target. A buffer object is bound by calling

```
   void BindBuffer(enum target, uint buffer);
```

/target/ must be one of ARRAY_BUFFER, ELEMENT_ARRAY_BUFFER, PIXEL_UNPACK_BUFFER_ARB, or PIXEL_PACK_BUFFER_ARB. The ARRAY_BUFFER target is discussed in section 2.9.1 The ELEMENT_ARRAY_BUFFER target is discussed in section 2.9.2. The PIXEL_UNPACK_BUFFER_ARB and PIXEL_PACK_BUFFER_ARB targets are discussed later in sections 3.6, 4.3.2, and 6.1. If the buffer object named /buffer/ has not been previously bound or has been deleted since the last binding, the GL creates a new state vector, initialized with a zero-sized memory buffer and comprising the state values listed in table 2.6."

Replace the 5th paragraph with:

"Initially, each buffer object target is bound to zero. There is no buffer object corresponding to the name zero so client attempts to modify or query buffer object state for a target bound to zero generate an INVALID_OPERATION error."

Replace the phrase listing the valid targets for BufferData in the 9th paragraph with:

"with target set to one of ARRAY_BUFFER, ELEMENT_ARRAY_BUFFER, PIXEL_UNPACK_BUFFER_ARB, or PIXEL_PACK_BUFFER_ARB,"

In the 10th paragraph describing buffer object usage modes, replace the phrase "specified once" with "specified once per repetition of the usage pattern" for the STREAM_* and STATIC_* usage values.

Also in the 10th paragraph describing buffer object usage modes, replace the phrases "of a GL drawing command." and "for GL drawing commands." with "for GL drawing and image specification commands." for the *_DRAW and *_COPY usage values.

Replace the phrase listing the valid targets for BufferSubData in the 15th paragraph with:

"with target set to one of ARRAY_BUFFER, ELEMENT_ARRAY_BUFFER, PIXEL_UNPACK_BUFFER_ARB, or PIXEL_PACK_BUFFER_ARB."

Replace the phrase listing the valid targets for MapBuffer in the 16th paragraph with:

"with target set to one of ARRAY_BUFFER, ELEMENT_ARRAY_BUFFER, PIXEL_UNPACK_BUFFER_ARB, or PIXEL_PACK_BUFFER_ARB."

Replace the phrase listing the valid targets for UnmapBuffer in the 21st paragraph with:

"with target set to one of ARRAY_BUFFER, ELEMENT_ARRAY_BUFFER, PIXEL_UNPACK_BUFFER_ARB, or PIXEL_PACK_BUFFER_ARB."

-- Section 2.9.2 "Array Indices in Buffer Objects"

Delete the 3rd paragraph that explains how the ELEMENT_ARRAY_BUFFER target is acceptable for the commands specified in section 2.9. The updated section 2.9 language already says this.

-- NEW Section 2.9.3 "Buffer Object Required State"

"The state required to support buffer objects consists of binding names for the array buffer, element buffer, pixel unpack buffer, and pixel pack buffer. Additionally, each vertex array has an associated binding so there is a buffer object binding for each of the vertex array, normal array, color array, index array, multiple texture coordinate arrays, edge flag array, secondary color array, fog coordinate array, and vertex attribute arrays. The initial values for all buffer object bindings is zero.

The state of each buffer object consists of a buffer size in basic machine units, a usage parameter, an access parameter, a mapped boolean, a pointer to the mapped buffer (NULL if unmapped), and the sized array of basic machine units for the buffer data."

Additions to Chapter 3 of the 1.2.1 Specification (Rasterization)

-- Section 3.6 "Pixel Rectangles"

Replace the 1st sentence in the 2nd paragraph:

"A number of parameters control the encoding of pixels in buffer object or client memory (for reading and writing) and how pixels are processed before being placed in or after being read from the framebuffer (for reading, writing, and copying)."

-- RENAME Section 3.6.1 "Pixel Storage Modes and Pixel Buffer Objects"

Add to the end of the section:

"In addition to storing pixel data in client memory, pixel data may also be stored in buffer objects (described in section 2.9). The current pixel unpack and pack buffer objects are designated by the PIXEL_UNPACK_BUFFER_ARB and PIXEL_PACK_BUFFER_ARB targets respectively.

Initially, zero is bound for the PIXEL_UNPACK_BUFFER_ARB, indicating that image specification commands such as DrawPixels source their pixels from client memory pointer parameters. However, if a non-zero buffer object is bound as the current pixel unpack buffer, then the pointer parameter is treated as an offset into the designated buffer object."

-- Section 3.6.3 "Pixel Transfer Modes", page 116.

Replace the last phrase in the 2nd paragraph with:

"and /values/ refers to an array of size map values."

[values is no longer necessarily a pointer.]

Add the following paragraph after the third paragraph:

"If a pixel unpack buffer is bound (as indicated by a non-zero value of PIXEL_UNPACK_BUFFER_BINDING_ARB), /values/ is an offset into the pixel unpack buffer; otherwise, /values/ is a pointer to a block client memory. All pixel storage and pixel transfer modes are ignored when specifying a pixel map. n machine units are read where n is the /size/ of the pixel map times the size of a float, uint, or ushort datum in basic machine units, depending on the respective PixelMap version. If a pixel unpack buffer object is bound and data+n is greater than the size of the pixel buffer, INVALID_OPERATION results. If a pixel unpack buffer object is bound and /values/ is not evenly divisible into the number of basic machine units needed to store in memory a float, uint, or ushort datum depending on their respective PixelMap version, INVALID_OPERATION results."

-- Section 3.6.4 "Rasterization of Pixel Rectangles", page 126.

Change the 1st sentence of the 1st paragraph to read:

"The process of drawing pixels encoded in buffer objects or client memory is diagrammed in figure 3.7."

Change the 4th sentence of the 2nd paragraph to read:

"/data/ refers to the data to be drawn."

[data is no longer necessarily a pointer.]

Change the initial phrase in the 1st sentence of the 1st paragraph after "Unpacking" to read:

"Data are taken from the currently bound pixel unpack buffer or client memory as a sequence of..."

Insert this paragraph after the 1st paragraph after "Unpacking":

"If a pixel unpack buffer is bound (as indicated by a non-zero value of PIXEL_UNPACK_BUFFER_BINDING_ARB), /data/ is an offset into the pixel unpack buffer and the pixels are unpacked from the buffer relative to this offset; otherwise, /data/ is a pointer to a block client memory and the pixels are unpacked from the client memory relative to the pointer. If a pixel unpack buffer object is bound and unpacking the pixel data according to the process described below would access memory beyond the size of the pixel unpack buffer's memory size, INVALID_OPERATION results. If a pixel unpack buffer object is bound and /data/ is not evenly divisible into the number of basic machine units needed to store in memory the corresponding GL data type from table 3.5 for the /type/ parameter, INVALID_OPERATION results."

-- Section 3.8.1 "Texture Image Specification", page 150.

Replace the last phrase in the 2nd to last sentence in the 1st paragraph with:

"and a reference to the image data in the currently bound pixel unpack buffer or client memory."

Replace the 1st sentence in the 13th paragraph with:

"The image itself (referred to by /data/) is a sequence of groups of values."

Replace the last paragraph with:

"If the data argument of TexImage1D, TexImage2D, or TexImage3D is a null pointer (a zero-valued pointer in the C implementation) and the pixel unpack buffer object is zero, a one-, two-, or three-dimensional texture array is created with the specified target, level, internalformat, width, height, and depth border, but with unspecified image contents. In this case no pixel values are access in client memory, and no pixel processing is performed. Errors are generated, however, exactly as though the data pointer were valid. Otherwise if the pixel unpack buffer object is non-zero, the data argument is treatedly normally to refer to the beginning of the pixel unpack buffer object's data."

-- Section 3.8.3 "Compressed Texture Images", page 163.

Replace the 3rd sentence of the 2nd paragraph with:

"/data/ refers to compressed image data stored in the compressed image format corresponding to internalformat. If a pixel unpack buffer is bound (as indicated by a non-zero value of PIXEL_UNPACK_BUFFER_BINDING_ARB), /data/ is an offset into the pixel unpack buffer and the compressed data is read from the buffer relative to this offset; otherwise, /data/ is a pointer to a block client memory and the compressed data is read from the client memory relative to the pointer."

Replace the 2nd sentence in the 3rd paragraph with:

"Compressed texture images are treated as an array of /imageSize/ ubytes relative to /data/. If a pixel unpack buffer object is bound and data+imageSize is greater than the size of the pixel buffer, INVALID_OPERATION results."

Additions to Chapter 4 of the 1.2.1 Specification (Per-Fragment Operations and the Frame Buffer)

-- Section 4.3.2 "Reading Pixels", page 219.

Replace 1st sentence of the 1st paragraph with:

"The method for reading pixels from the framebuffer and placing them in pixel pack buffer or client memory is diagrammed in figure 4.2."

Add this paragraph after the 1st paragraph:

"Initially, zero is bound for the PIXEL_PACK_BUFFER_ARB, indicating that image read and query commands such as ReadPixels return pixels results into client memory pointer parameters. However, if a non-zero buffer object is bound as the current pixel pack buffer, then the pointer parameter is treated as an offset into the designated buffer object."

Rename "Placement in Client Memory" to "Placement in Pixel Pack Buffer or Client Memory".

Insert this paragraph after the newly renamed "Placement in Pixel Pack Buffer or Client Memory" heading:

"If a pixel pack buffer is bound (as indicated by a non-zero value of PIXEL_PACK_BUFFER_BINDING_ARB), /data/ is an offset into the pixel pack buffer and the pixels are packed into the buffer relative to this offset; otherwise, /data/ is a pointer to a block client memory and the pixels are packed into the client memory relative to the pointer. If a pixel pack buffer object is bound and packing the pixel data according to the pixel pack storage state would access memory beyond the size of the pixel pack buffer's memory size, INVALID_OPERATION results. If a pixel pack buffer object is bound and /data/ is not evenly divisible into the number of basic machine units needed to store in memory the corresponding GL data type from table 3.5 for the /type/ parameter, INVALID_OPERATION results."

Additions to Chapter 5 of the 1.2.1 Specification (Special Functions)

None

Additions to Chapter 6 of the 1.2.1 Specification (State and State Requests)

-- Section 6.1.3 "Enumerated Queries".

After the sentence in the last paragraph describing GetPixelMap, add:

"The GetPixelMapfv, GetPixelMapuiv, and GetPixelMapusv commands write all the values in the named pixel map to /data/. If a pixel pack buffer is bound (as indicated by a non-zero value of PIXEL_PACK_BUFFER_BINDING_ARB), /data/ is an offset into the pixel pack buffer; otherwise, /data/ is a pointer to a block client memory. All pixel storage and pixel transfer modes are ignored when returning a pixel map. n machine units are written where n is the size of the pixel map times the size of FLOAT, UNSIGNED_INT, or UNSIGNED_SHORT respectively in basic machine units. If a pixel pack buffer object is bound and data+n is greater than the size of the pixel buffer, generate INVALID_OPERATION."

-- Section 6.1.4 "Texture Queries".

Remove the mention of img in the last phrase in the last sentence of the 1st paragraph so the sentence reads:

"lod is a level-of-detail number, format is a pixel format from table 3.6, and type is a pixel type from table 3.5."

Replace the 3rd sentence of the 2nd paragraph with:

"These groups are then packed and placed in client or pixel buffer object memory. If a pixel pack buffer is bound (as indicated by a non-zero value of PIXEL_PACK_BUFFER_BINDING_ARB), /img/ is an offset into the pixel pack buffer; otherwise, /img/ is a pointer to a block client memory."

Add to the end of the 4th paragraph:

"If a pixel pack buffer object is bound and packing the texture image into the buffer's memory would exceed the size of the buffer, generate INVALID_OPERATION."

Replace the 2nd sentence of the 5th paragraph with:

"When called, GetCompressedTexImage writes n ubytes of compressed image data to the pixel pack buffer or client memory pointed to by ptr, where n is the texture image's TEXTURE_COMPRESSED_IMAGE_SIZE value.

Add to the end of the 6th paragraph:

"If a pixel pack buffer object is bound and ptr+n is greater than the size of the buffer, generate INVALID_OPERATION."

-- Section 6.1.5 "Stipple Query".

"The pattern is packed into client or pixel pack buffer memory according to the procedures given in section 4.3.2 for ReadPixels; ..."

-- Section 6.1.7 "Color Table Query".

"The one-dimensional color table image is returned to client or pixel pack buffer memory starting at table."

-- Section 6.1.8 "Convolution Query".

"The one-dimensional or two-dimensional image is returned to client or pixel pack buffer memory starting at image."

"The row and column images are returned to client or pixel pack buffer memory starting at row and column respectively."

-- Section 6.1.9 "Histogram Query".

"The one-dimensional histogram table image is returned to client or pixel pack buffer memory starting at values."

-- Section 6.1.10 "Minmax Query".

"A one-dimensional image of width 2 is returned to client or pixel pack buffer memory starting at values."

-- Section 6.1.13 "Buffer Object Queries".

Change the 2nd sentence of the 2nd paragraph to read:

"target is ARRAY_BUFFER, ELEMENT_ARRAY_BUFFER, PIXEL_PACK_BUFFER_ARB, or PIXEL_UNPACK_BUFFER_ARB."

Change the last phrase in the 1st sentence of the 4th paragraph to:

"with target set to ARRAY_BUFFER, ELMENT_ARRAY_BUFFER, PIXEL_PACK_BUFFER_ARB, or PIXEL_UNPACK_BUFFER_ARB and pname set to BUFFER_MAP_POINTER."

GLX Protocol

XXX still-in-progress

(ARB_vertex_buffer_object has similar issues and lacks specified GLX protocol for its functionality. This discussion just addresses the issues created by pixel buffer objects, not buffer objects in general.)

Pixel buffers, like texture objects and display lists, are server-side state.

Prior to pixel buffer objects, pixel storage state for image packing and unpacking was considered client-side state. However, pixel buffers create the new situation where the server performs packing and unpacking into server-side pixel buffers.

The GLX protocol is designed so that the amount of unpacking done by the client is parameterized with the request. In other words, the client can do as much unpacking as it wants, and then tell the server what unpacking remains to be done by sending the appropriate pixel storage parameters along with the image.

This means the GLX protocol for rendering commands involving pixel data includes pixel store state for unpacking.

This means, in theory, the existing protocol for rendering commands with pixel data is sufficient for manipulating pixel buffers.
A command (for example, glDrawPixels) could build a protocol request containing the current pixel unpack state and specify zero bytes of image payload when operating on a pixel buffer object.

In practice, while this addresses command requiring unpacking of pixel data, commands that require packing of pixel data (for example, glReadPixels) to return pixel data do not have protocol fields for pixel store pack state.

Fortunately, the GLX protocol, through foresight or oversight, has GLX protocol and non-rendering command opcodes (109 and 110) assigned for glPixelStoref and glPixelStorei respectively.

It is better to use the existing protocol to send glPixelStorei and glPixelStoref GLX commands. This solves the problem of server-side pixel state the same way for both pack and unpack state. It may also allow implementations to minimize validation overhead for pixel commands because the pixel store modes are stateful rather than being parameters sent with every pixel command.

To avoid creating useless protocol overhead for applications not using pixel buffer objects, and hence not requiring server-side knowledge of pixel store state, the GLX client library is free to defer pixel store commands until just prior to pixel commands operating on pixel buffer objects that require server-side pixel store state.

There is no GLX protocol however for glPushClientAttrib and glPopClientAttrib. New protocol should be specified for these commands. These commands are also needed for vertex buffer objects because the vertex array state becomes server-side.

When bound to an pixel unpack buffer object, the pixel payload for a non-reply pixel command (for example, glTexImage2D) can be ignored. In fact, GLX client implementations are expected to send zero bytes of pixel payload in this case.

When bound to a pixel pack buffer object, the reply for pixel commands that return pixel data (for example, glReadPixels) is not required since the pixel data is actually transferred to the server-side pixel pack buffer object. Indeed, forcing an unnecessary reply would hinder the performance advantages of using pixel buffer objects

```
    Therefore, protocol for "no reply" version of the following commands
    is specified:

        GetCompressedTexImage_noreply
        GetConvolutionFilter_noreply
        GetHistogram_noreply
        GetMinmax_noreply
        GetPixelMapfv_noreply
        GetPixelMapuiv_noreply
        GetPixelMapusv_noreply
        GetPolygonStipple_noreply
        GetSeparableFilter,_noreply
        GetTexImage_noreply
        ReadPixels_noreply

    If a "no reply" command is sent when the current pixel pack
    buffer object binding is zero, a GLXBadContextState error should
    be generated by the server.
```

Errors

```
    INVALID_ENUM is generated if the <target> parameter of
    BindBuffer, BufferData, BufferSubData, MapBuffer, UnmapBuffer,
    GetBufferSubData, GetBufferParameteriv, or GetBufferPointerv is not
    one of ARRAY_BUFFER, ELEMENT_ARRAY_BUFFER, PIXEL_PACK_BUFFER_ARB,
    or PIXEL_UNPACK_BUFFER_ARB.

    INVALID_OPERATION is generated if Bitmap, ColorSubTable, ColorTable,
    CompressedTexImage1D, CompressedTexImage2D, CompressedTexImage3D,
    CompressedTexSubImage1D, CompressedTexSubImage2D,
    CompressedTexSubImage3D, ConvolutionFilter1D, ConvolutionFilter2D,
    DrawPixels, PixelMapfv, PixelMapuiv, PixelMapusv, PolygonStipple,
    SeparableFilter2D, TexImage1D, TexImage2D, TexImage3D, TexSubImage1D,
    TexSubImage2D, or TexSubImage3D would unpack (read) data from the
    currently bound PIXEL_UNPACK_BUFFER_ARB buffer object such that
    the memory reads required for the command would exceed the memory
    (data store) size of the buffer object.

    INVALID_OPERATION is generated if GetColorTable,
    GetCompressedTexImage, GetConvolutionFilter, GetHistogram, GetMinmax,
    GetPixelMapfv, GetPixelMapuiv, GetPixelMapusv, GetPolygonStipple,
    GetSeparableFilter, GetTexImage, or ReadPixels would pack (write) data
    to the currently bound PIXEL_PACK_BUFFER_ARB buffer object such that
    the memory writes required for the command would exceed the memory
    (data store) size of the buffer object.

    INVALID_OPERATION is generated by GetColorTable, GetConvolutionFilter,
    GetHistogram, GetMinmax, GetSeparableFilter, GetTexImage and ReadPixels
    if the current PIXEL_PACK_BUFFER_BINDING_ARB value is non-zero and the
    table/image/values/span/img/data parameter is not evenly divisible
    into the number of basic machine units needed to store in memory a
    datum indicated by the type parameter.

    INVALID_OPERATION is generated by ColorTable, ColorSubTable,
    ConvolutionFilter2D, ConvolutionFilter1D, SeparableFilter2D,
    TexImage1D, TexImage2D, TexImage3D, TexSubImage1D,
    TexSubImage2D, TexSubImage3D, and DrawPixels if the current
```

PIXEL_UNPACK_BUFFER_BINDING_ARB value is non-zero and the data parameter is not evenly divisible into the number of basic machine units needed to store in memory a datum indicated by the type parameter.

INVALID_OPERATION is generated by GetPixelMapfv if the current PIXEL_PACK_BUFFER_BINDING_ARB value is non-zero and the data parameter is not evenly divisible into the number of basic machine units needed to store in memory a float datum.

INVALID_OPERATION is generated by GetPixelMapuiv if the current PIXEL_PACK_BUFFER_BINDING_ARB value is non-zero and the data parameter is not evenly divisible into the number of basic machine units needed to store in memory a uint datum.

INVALID_OPERATION is generated by GetPixelMapusv if the current PIXEL_PACK_BUFFER_BINDING_ARB value is non-zero and the data parameter is not evenly divisible into the number of basic machine units needed to store in memory a ushort datum.

INVALID_OPERATION is generated by PixelMapfv if the current PIXEL_UNPACK_BUFFER_BINDING_ARB value is non-zero and the data parameter is not evenly divisible into the number of basic machine units needed to store in memory a float datum.

INVALID_OPERATION is generated by PixelMapuiv if the current PIXEL_UNPACK_BUFFER_BINDING_ARB value is non-zero and the data parameter is not evenly divisible into the number of basic machine units needed to store in memory a uint datum.

INVALID_OPERATION is generated by PixelMapusv if the current PIXEL_UNPACK_BUFFER_BINDING_ARB value is non-zero and the data parameter is not evenly divisible into the number of basic machine units needed to store in memory a ushort datum.

Dependencies on EXT_pixel_buffer_object

When this extension is supported, the EXT_pixel_buffer_object functionality adopts the tighter alignment and buffer bounds overflow error generation behavior of ARB_pixel_buffer_object (previously, EXT_pixel_buffer_object was not explicit about what happened in these situations). This is because the two extensions share the same enumerants.

Dependencies on NV_pixel_data_range

A non-zero pixel pack buffer binding takes priority over the READ_PIXEL_DATA_RANGE_NV enable.

A non-zero pixel unpack buffer binding takes priority over the WRITE_PIXEL_DATA_RANGE_NV enable.

New State

(table 6.20, Pixels, p. 235)

Get Value	Type	Get Command	Initial Value	Sec	Attribute
PIXEL_PACK_BUFFER_BINDING_ARB	Z+	GetIntegerv	0	4.3.5	pixel-store
PIXEL_UNPACK_BUFFER_BINDING_ARB	Z+	GetIntegerv	0	6.1.13	pixel-store

New Implementation Dependent State

(none)

Usage Examples

Convenient macro definition for specifying buffer offsets:

```
#define BUFFER_OFFSET(i) ((char *)NULL + (i))
```

Example 1: Render to vertex array:

```
const int numberVertices = 100;

// Create a buffer object for a number of vertices consisting of
// 4 float values per vertex
glGenBuffers(1, vertexBuffer);
glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, vertexBuffer);
glBufferData(GL_PIXEL_PACK_BUFFER_ARB, numberVertices*4,
             NULL, GL_DYNAMIC_DRAW);

// Render vertex data into 100x1 strip of framebuffer using a
// fragment program
glBindProgram(FRAGMENT_PROGRAM_ARB, fragmentProgram);
glDrawBuffer(GL_BACK);
renderVertexData();
glBindProgramARB(FRAGMENT_PROGRAM_ARB, 0);

// Read the vertex data back from framebuffer
glReadBuffer(GL_BACK);
glReadPixels(0, 0, numberVertices, 1, GL_BGRA, GL_FLOAT,
             BUFFER_OFFSET(0));

// Change the binding point of the buffer object to
// the vertex array binding point
glBindBuffer(GL_ARRAY_BUFFER, vertexBuffer);

glEnableClientState(VERTEX_ARRAY);
glVertexPointer(4, GL_FLOAT, 0, BUFFER_OFFSET(0));
glDrawArrays(TRIANGLE_STRIP, 0, numberVertices);
```

Example 2: Streaming textures

Streaming textures using NV_pixel_data_range:

```
    const int texWidth = 256;
    const int texHeight = 256;
    const int texsize = texWidth * texHeight * 4;
    void *pdrMemory, *texData;

    pdrMemory = glAllocateMemoryNV(texsize, 0.0, 1.0, 1.0);

    glPixelDataRangeNV(GL_WRITE_PIXEL_DATA_RANGE_NV, texsize,
                       pdrMemory);

    glEnableClientState(GL_WRITE_PIXEL_DATA_RANGE_NV);

    // Define texture level (without an image)
    glTexImage2D(GL_TEXTURE_2D, 0, GL_RGBA8, texWidth, texHeight, 0,
                 GL_BGRA, GL_UNSIGNED_BYTE, NULL);
    // Setup texture environment
    ...

    texData = getNextImage();

    while (texData) {

        memcpy(pdrMemory, texData, texsize);

        glFlushPixelDataRangeNV(GL_WRITE_PIXEL_DATA_RANGE_NV);

        glTexSubImage2D(GL_TEXTURE_2D, 0, 0, 0, texWidth, texHeight,
                        GL_BGRA, GL_UNSIGNED_BYTE, pdrMemory);

        // Draw textured geometry
        glBegin(GL_QUADS);
        ...
        glEnd();

        texData = getNextImage();
    }

    glDisableClientState(GL_WRITE_PIXEL_DATA_RANGE_NV);

    glFreeMemoryNV(pdrMemory);
```

Streaming textures using pixel buffer objects:

```
    const int texWidth = 256;
    const int texHeight = 256;
    const int texsize = texWidth * texHeight * 4;
    void *pboMemory, *texData;

    // Define texture level zero (without an image); notice the
    // explicit bind to the zero pixel unpack buffer object so that
    // pass NULL for the image data leaves the texture image
    // unspecified.
    glBindBuffer(GL_PIXEL_UNPACK_BUFFER_ARB, 0);
    glTexImage2D(GL_TEXTURE_2D, 0, GL_RGBA8, texWidth, texHeight, 0,
                 GL_BGRA, GL_UNSIGNED_BYTE, NULL);

    // Create and bind texture image buffer object
    glGenBuffers(1, &texBuffer);
    glBindBuffer(GL_PIXEL_UNPACK_BUFFER_ARB, texBuffer);

    // Setup texture environment
    ...

    texData = getNextImage();

    while (texData) {

        // Reset the contents of the texSize-sized buffer object
        glBufferData(GL_PIXEL_UNPACK_BUFFER_ARB, texSize, NULL,
                     GL_STREAM_DRAW);

        // Map the texture image buffer (the contents of which
        // are undefined due to the previous glBufferData)
        pboMemory = glMapBuffer(GL_PIXEL_UNPACK_BUFFER_ARB,
                                GL_WRITE_ONLY);

        // Modify (sub-)buffer data
        memcpy(pboMemory, texData, texsize);

        // Unmap the texture image buffer
        glUnmapBuffer(GL_PIXEL_UNPACK_BUFFER_ARB);

        // Update (sub-)teximage from texture image buffer
        glTexSubImage2D(GL_TEXTURE_2D, 0, 0, 0, texWidth, texHeight,
                        GL_BGRA, GL_UNSIGNED_BYTE, BUFFER_OFFSET(0));

        // Draw textured geometry
        glBegin(GL_QUADS);
        ...
        glEnd();

        texData = getNextImage();
    }

    glBindBuffer(GL_PIXEL_UNPACK_BUFFER_ARB, 0);
```

Example 3: Asynchronous glReadPixels

Traditional glReadPixels:

```
const int imagewidth = 640;
const int imageheight = 480;
GLubyte readBuffer[imagewidth*imageheight*4];

// Render to framebuffer
glDrawBuffer(GL_BACK);
renderScene()

// Read image from framebuffer
glReadBuffer(GL_BACK);
glReadPixels(0, 0, imagewidth, imageheight, GL_BGRA,
             GL_UNSIGNED_BYTE, readBuffer);

// Process image when glReadPixels returns after reading the
// whole buffer
processImage(readBuffer);
```

Asynchronous glReadPixels:

```
const int imagewidth = 640;
const int imageheight = 480;
const int imageSize = imagewidth*imageheight*4;

glGenBuffers(2, imageBuffers);

glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, imageBuffers[0]);
glBufferData(GL_PIXEL_PACK_BUFFER_ARB, imageSize / 2, NULL,
             GL_STREAM_READ);

glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, imageBuffers[1]);
glBufferData(GL_PIXEL_PACK_BUFFER_ARB, imageSize / 2, NULL,
             GL_STREAM_READ);

// Render to framebuffer
glDrawBuffer(GL_BACK);
renderScene();

// Bind two different buffer objects and start the glReadPixels
// asynchronously. Each call will return directly after
// starting the DMA transfer.
glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, imageBuffers[0]);
glReadPixels(0, 0, imagewidth, imageheight/2, GL_BGRA,
             GL_UNSIGNED_BYTE, BUFFER_OFFSET(0));

glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, imageBuffers[1]);
glReadPixels(0, imageheight/2, imagewidth, imageheight/2, GL_BGRA,
             GL_UNSIGNED_BYTE, BUFFER_OFFSET(0));

// Process partial images.  Mapping the buffer waits for
// outstanding DMA transfers into the buffer to finish.
glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, imageBuffers[0]);
pboMemory1 = glMapBuffer(GL_PIXEL_PACK_BUFFER_ARB,
                         GL_READ_ONLY);
```

```
        processImage(pboMemory1);
        glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, imageBuffers[1]);
        pboMemory2 = glMapBuffer(GL_PIXEL_PACK_BUFFER_ARB,
                                 GL_READ_ONLY);
        processImage(pboMemory2);

        // Unmap the image buffers
        glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, imageBuffers[0]);
        glUnmapBuffer(GL_PIXEL_PACK_BUFFER_ARB);
        glBindBuffer(GL_PIXEL_PACK_BUFFER_ARB, imageBuffers[1]);
        glUnmapBuffer(GL_PIXEL_PACK_BUFFER_ARB);
```

Appendix on Pack/Unpack Range

The complexity of OpenGL's pixel pack/unpack state makes it difficult to express succinctly what range of a pixel buffer object will be accessed by a pixel command.

The following code, following the conventions of the SGI OpenGL Sample Implementation, returns the limit (one byte more than the maximum allowed offset into the buffer object) for the memory a pixel command will read/write.

```
    /*
    ** Compute offset limit into user's data considering all pixel
    ** store modes.  This offset limit is ONE MORE than the largest byte
    ** offset for the image.
    */
    static GLsizeiptr OffsetLimitImage3D(__GLpixelStoreMode *pixelStoreMode,
                                         GLsizei width, GLsizei height,
                                         GLsizei depth,
                                         GLenum format, GLenum type,
                                         const GLvoid *userdata,
                                         GLint skip_images)
    {
        const GLint line_length = pixelStoreMode->lineLength;
        const GLint image_height = pixelStoreMode->imageHeight;
        const GLint alignment = pixelStoreMode->alignment;
        const GLint skip_pixels = pixelStoreMode->skipPixels;
        const GLint skip_lines = pixelStoreMode->skipLines;

        GLsizeiptr offsetLimit = (GLsizeiptr) userdata;

        GLint rowsize;
        GLint padding;
        GLint imagesize;

        assert(width > 0);
        assert(height > 0);
        assert(depth > 0);

        assert(line_length >= 0);
        assert(image_height >= 0);

        assert(skip_pixels >= 0);
        assert(skip_lines >= 0);
        assert(skip_images >= 0);
        assert((alignment == 1) ||
               (alignment == 2) ||
               (alignment == 4) ||
               (alignment == 8));

        /* All formats except GL_BITMAP fall out trivially */
        if (type == GL_BITMAP) {
            const GLint groups_per_line = (line_length > 0) ?
                                          line_length : width;
            const GLint rows_per_image = (image_height > 0) ?
                                         image_height : height;

            assert(1 == __glElementsPerGroup(format, type));

            rowsize = (groups_per_line + 7) / 8;
            padding = rowsize & (alignment-1);
            if (padding) {
                rowsize += alignment - padding;
            }
            imagesize = rows_per_image * rowsize;

            offsetLimit += imagesize    * (skip_images + depth-1);
            offsetLimit += rowsize      * (skip_lines  + height-1);
            offsetLimit += (skip_pixels + width+7)/8;
        } else {

    }
```

Revision History

    revision 0.3: mjk

        Numbered issues.

        Add issues 14 through 18.

        Remove all gl/GL prefix/suffixing in specification sections. Use
        gl/GL prefix/suffixing in sections other than the specification
        sections. Leaving off prefixes in non-specification sections is
        ambiguous, particularly within example source code.

        Base specification language updates on OpenGL 2.0 specification.

        Add buffer object required state section.

        Added GL_INVALID_OPERATION when an offset accessed (read or
        written) for a pixel command from/to a pixel buffer object would
        exceed the size of the buffer object.

        Added GL_INVALID_OPERATION when for misaligned offsets.

```
        Added "Appendix on Pack/Unpack Range".

        Add GLX protocol discussion.

    revision 0.4: mjk

        Fixed grammar issues from Brian Paul.

        Improved example code and fixed grammar from Nick Carter.

        Explain how a NULL data parameter to glTexImage commands works.

    revision 0.5: mjk

        Clarify that glBufferData usage modes apply to drawing _and_
        image specification commands.

    revision 0.6: mjk

        Add "streaming draw pixels" to the list of interesting approaches
        for this extension in the Overview.

        Add issue discussing the relationship of this extension to data
        aquisition hardware.

    revision 0.7: mjk

        Assign enumerant values to match the EXT_pixel_buffer_object values.

        Add issue explaining why the ARB extension shares enums with
        EXT_pixel_buffer_object.

        Apply Dale's suggestion to improve the clarity of the usage
        pattern parameters to glBufferData.

    revision 0.8 mjk

        Typo fixes from Ian Romanick and Nick Carter.

    revision 1.0 mjk

        Add issue 23 for Jeremy about render-to-vertex-array.  Move
        render-to-vertex-array justification in overview to bottom of
        the list.
```

Number

    ARB Extension #14

Dependencies

    OpenGL 1.0 is required.
    ARB_multisample affects the definition of this extension.
    The extension is written against the OpenGL 1.2.1 Specification.

Overview

This extension supports additional geometric characteristics of points. It can be used to render particles or tiny light sources, commonly referred to as "Light points".

The raster brightness of a point is a function of the point area, point color, point transparency, and the response of the display's electron gun and phosphor. The point area and the point transparency are derived from the point size, currently provided with the <size> parameter of glPointSize.

The primary motivation is to allow the size of a point to be affected by distance attenuation. When distance attenuation has an effect, the final point size decreases as the distance of the point from the eye increases.

The secondary motivation is a mean to control the mapping from the point size to the raster point area and point transparency. This is done in order to increase the dynamic range of the raster brightness of points. In other words, the alpha component of a point may be decreased (and its transparency increased) as its area shrinks below a defined threshold.

This extension defines a derived point size to be closely related to point brightness. The brightness of a point is given by:

```
                    1
dist_atten(d) = -------------------
                a + b * d + c * d^2

brightness(Pe) = Brightness * dist_atten(|Pe|)
```

where 'Pe' is the point in eye coordinates, and 'Brightness' is some initial value proportional to the square of the size provided with PointSize. Here we simplify the raster brightness to be a function of the rasterized point area and point transparency.

```
            brightness(Pe)       brightness(Pe) >= Threshold_Area
area(Pe) =
            Threshold_Area       Otherwise

factor(Pe) = brightness(Pe)/Threshold_Area

alpha(Pe) = Alpha * factor(Pe)
```

where 'Alpha' comes with the point color (possibly modified by lighting).

'Threshold_Area' above is in area units. Thus, it is proportional to the square of the threshold provided by the programmer through this extension.

The new point size derivation method applies to all points, while the threshold applies to multisample points only.

IP Status

None.

Issues

* *Does point alpha modification affect the current color ?*

No.

* *Do we need a special function GetPointParameterfvARB, or get by with GetFloat ?*

GetFloat is sufficient.

* *If alpha is 0, then we could toss the point before it reaches the fragment stage.*

No. This can be achieved with enabling the alpha test with reference of 0 and function of LEQUAL.

* *Do we need a disable for applying the threshold ? The default threshold value is 1.0. It is applied even if the point size is constant.*

If the default threshold is not overridden, the area of multisample points with provided constant size of less than 1.0, is mapped to 1.0, while the alpha component is modulated accordingly, to compensate for the larger area. For multisample points this is not a problem, as there are no relevant applications yet. As mentioned above, the threshold does not apply to alias or antialias points.

The alternative is to have a disable of threshold application, and state that threshold (if not disabled) applies to non antialias points only (that is, alias and multisample points).

The behavior without an enable/disable looks fine.

* *Future extensions (to the extension)*

1. POINT_FADE_ALPHA_CLAMP_ARB

When the derived point size is larger than the threshold size defined by the POINT_FADE_THRESHOLD_SIZE_ARB parameter, it might be desired to clamp the computed alpha to a minimum value, in order to keep the point visible. In this case the formula below change:

```
factor = (derived_size/threshold)^2

                factor                  clamp <= factor
clamped_value =
                clamp                   factor < clamp

         1.0                            derived_size >= threshold
alpha *=
         clamped_value                  Otherwise
```

where clamp is defined by the POINT_FADE_ALPHA_CLAMP_ARB new parameter.

New Procedures and Functions

```
void PointParameterfARB(enum pname,
                        float param);
void PointParameterfvARB(enum pname,
                         float *params);
```

New Tokens

Accepted by the <pname> parameter of PointParameterfARB, and the <pname> of Get:

```
POINT_SIZE_MIN_ARB
POINT_SIZE_MAX_ARB
POINT_FADE_THRESHOLD_SIZE_ARB
```

    Accepted by the <pname> parameter of PointParameterfvARB, and the
    <pname> of Get:

```
        POINT_SIZE_MIN_ARB               0x8126
        POINT_SIZE_MAX_ARB               0x8127
        POINT_FADE_THRESHOLD_SIZE_ARB    0x8128
        POINT_DISTANCE_ATTENUATION_ARB   0x8129
```

Additions to Chapter 2 of the OpenGL 1.2.1 Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the OpenGL 1.2.1 Specification (Rasterization)

In section 3.3, the following is inserted after the description of PointSize:

The point size is multiplied with a distance attenuation factor and clamped as follows:

```
        derived_size = Clamp(size * sqrt(dist_atten(dist)))
```

where dist_atten is specified as

```
                                 1
        dist_atten(d) = -------------------
                        a + b * d + c * d^2
```

and 'd' is the eye-coordinate distance from the eye, (0, 0, 0, 1) in eye coordinates, to the vertex.

The derived point size is clamped to a given range, and then clamped to the implementation-dependent point size range.

If multisampling is enabled, an implementation may optionally fade the point alpha (section 3.12) instead of allowing the size to go below a given threshold. In this case, the diameter of the rasterized point is

```
                   derived_size                derived_size >= threshold
        diameter =
                   threshold                   Otherwise
```

and the fade factor is computed as follows:

```
                 1                             derived_size >= threshold
        fade =
                 (derived_size/threshold)^2    Otherwise
```

The distance attenuation function coefficients, 'a', 'b', and 'c', the bounds of the clamp, and the point fade 'threshold', are specified with

```
        void PointParameterfARB( enum pname, float param );
        void PointParameterfvARB( enum pname, const float *params );
```

If <pname> is POINT_SIZE_MIN_ARB or POINT_SIZE_MAX_ARB, then <param> specifies, or <params> points to the lower or upper bound respectively on the derived point size. If the lower bound is greater than the upper bound, the resulting point size is undefined. If <pname> is POINT_DISTANCE_ATTENUATION_ARB, then <params> points to the coefficients 'a', 'b', and 'c'. If <pname> is POINT_FADE_THRESHOLD_SIZE_ARB, <param> specifies, or <params> points to the point fade threshold.

This extension doesn't change the feedback or selection behavior of points.

In section 3.11, the word "Finally" is removed from the first sentence.

Add the following after section 3.11.

Section 3.12 Multisample Point Fade

If multisampling is enabled and the rasterized fragment results from a point primitive, then the computed fade factor is applied to the fragment. In RGBA mode, the fade factor is multiplied by the fragment's alpha (A) value to yield a final alpha value. In color index mode, the fade factor has no effect.

GLX Protocol

Two new GL rendering commands are added. The following commands are sent to the server as part of a glXRender request:

```
    PointParameterfARB
        2           8+4*n             rendering command length
        2           2065              rendering command opcode
        4           ENUM              pname
                    0x8126    n=1   POINT_SIZE_MIN_ARB
                    0x8127    n=1   POINT_SIZE_MAX_ARB
                    0x8128    n=1   POINT_FADE_THRESHOLD_SIZE_ARB
        4           FLOAT32           param

    PointParameterfvARB
        2           8+4*n             rendering command length
        2           2066              rendering command opcode
        4           ENUM              pname
                    0x8126    n=1   POINT_SIZE_MIN_ARB
                    0x8127    n=1   POINT_SIZE_MAX_ARB
                    0x8128    n=1   POINT_FADE_THRESHOLD_SIZE_ARB
                    0x8129    n=3   POINT_DISTANCE_ATTENUATION_ARB
        4*n         LISTofFLOAT32   params
```

Dependencies on ARB_multisample

If ARB_multisample is not implemented, then the references to multisample points are invalid, and should be ignored.

Errors

INVALID_ENUM is generated if PointParameterfARB parameter <pname> is not POINT_SIZE_MIN_ARB, POINT_SIZE_MAX_ARB, or POINT_FADE_THRESHOLD_SIZE_ARB.

INVALID_ENUM is generated if PointParameterfvARB parameter <pname> is not POINT_SIZE_MIN_ARB, POINT_SIZE_MAX_ARB, POINT_FADE_THRESHOLD_SIZE_ARB, or POINT_DISTANCE_ATTENUATION_ARB

INVALID_VALUE is generated when values are out of range according to:

<pname>	valid range
POINT_SIZE_MIN_ARB	>= 0
POINT_SIZE_MAX_ARB	>= 0
POINT_FADE_THRESHOLD_SIZE_ARB	>= 0

New State

(table 6.11, p. 201)

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
POINT_SIZE_MIN_ARB	R+	GetFloatv	0.0	Attenuated Min point size	3.3	point
POINT_SIZE_MAX_ARB	R+	GetFloatv	M	Attenuated Max point size	3.3	point
POINT_FADE_THRESHOLD_SIZE_ARB	R+	GetFloatv	1.0	Threshold for alpha attenuation	3.3	point
POINT_DISTANCE_ATTENUATION_ARB	3xR	GetFloatv	(1.0,0.0,0.0)	Attenuation coefficients	3.3	point

M is the larger of the max antialiased and non antialiased point sizes.

Revision History

```
11/09/1999  0.1
    - First ARB draft based on the original SGI and EXT drafts.

12/07/1999  0.2
    - clarified behavior when POINT_SIZE_MIN exceeds POINT_SIZE_MAX
    - clarified when the point size is clamped to the supported range
    - removed issues from "Errors" section
    - fixed various typos
    - Updated to new extension template
    - added GLX protocol

04/20/2000  0.3
    - rewritten to fit within the context of the 1.2 specification
    - added language describing where the fade alpha is applied.
    - added language which indicates that some implementations may not
      implement POINT_FADE_THRESHOLD_SIZE_ARB

06/20/2000  0.4
    - removed alternate behavior for fade alpha, since it is optional
    - added new section describing fade alpha application

03/12/2002  0.5
    - added GLX protocol for PointParameterfARB and assigned ropcodes
```

    ARB Extension #35

Dependencies

    Written based on the wording of the OpenGL 1.4 specification.

    NV_point_sprite affects the definition of this extension.

Overview

    Applications such as particle systems have tended to use OpenGL quads
    rather than points to render their geometry, since they would like
    to use a custom-drawn texture for each particle, rather than the
    traditional OpenGL round antialiased points, and each fragment in
    a point has the same texture coordinates as every other fragment.

    Unfortunately, specifying the geometry for these quads can be
    expensive, since it quadruples the amount of geometry required, and
    may also require the application to do extra processing to compute
    the location of each vertex.

    The purpose of this extension is to allow such applications to use
    points rather than quads. When GL_POINT_SPRITE_ARB is enabled,
    the state of point antialiasing is ignored. For each texture unit,
    the app can then specify whether to replace the existing texture
    coordinates with point sprite texture coordinates, which are
    interpolated across the point.

Issues

    *   *Should this spec say that point sprites get converted into quads?*

        RESOLVED: No, this would make the spec much uglier, because then
        we'd have to say that polygon smooth and stipple get turned off,

etc. Better to provide a formula for computing the texture
coordinates and leave them as points.

* *How are point sprite texture coordinates computed?*

RESOLVED: They move smoothly as the point moves around on the
screen, even though the pixels touched by the point do not. The
exact formula is given in the spec below.

A point sprite can be thought of as a quad whose upper-left corner
has (s,t) texture coordinates of (0,0) and whose lower-right
corner has texture coordinates of (1,1), as illustrated in
the following figure. In the figure "P" is the center of
the point sprite, and "O" is the origin (0,0) of the window
coordinate system. Note that the y window coordinate increases
from bottom-to-top but the t texture coordinate of point sprites
increases from top-to-bottom.

```
      ^
    +y| (0,0)
      |   +-----+
      |   |     |
      |   |  P  |
      |   |     |
      |   +-----+
      |       (1,1)
      |              +x
      O--------------->
```

Applications using a single texture for both point sprites and
other geometry need to account for the fixed coordinate mapping
of point sprites.

* *Is the ARB specification different from the NV version?*

RESOLVED: Yes. The point sprite R mode has been removed.
The wording has also been updated to reflect version 1.4 of the
core OpenGL specification however. The enumerant values are
unchanged.

* *How do point sizes for point sprites work?*

RESOLVED: This specification treats point sprite sizes like
antialiased point sizes, but with more leniency. Implementations
may choose to not clamp the point size to the antialiased point
size range. The set of point sprite sizes available must be
a superset of the antialiased point sizes. However, whereas
antialiased point sizes are all evenly spaced by the point size
granularity, point sprites can have an arbitrary set of sizes.
This lets implementations use, e.g., floating-point sizes.

* *Should there be a way to query the list of supported point sprite
sizes?*

RESOLVED: No. If an implementation were to use, say, a single-
precision IEEE float to represent point sizes, the list would
be rather long.

* *Do mipmaps apply to point sprites?*

  RESOLVED: Yes. They are similar to quads in this respect.

* *What of this extension's state is per-texture unit and what of this extension's state is state is global?*

  RESOLVED: The GL_POINT_SPRITE_ARB enable is global.
  The COORD_REPLACE_ARB state is per-texture unit (state set by TexEnv is per-texture unit).

* *Should there be a global on/off switch for point sprites, or should the per-unit enable imply that switch?*

  RESOLVED: There is a global switch to turn it on and off. This is probably more convenient for both driver and app, and it simplifies the spec.

* *What should the TexEnv mode for point sprites be called?*

  RESOLVED: COORD_REPLACE_ARB.

* *What is the interaction with multisample points, which are round?*

  RESOLVED: Point sprites are rasterized as squares, even in multisample mode. Leaving them as round points would make the feature useless.

* *How does the point sprite extension interact with fragment program extensions (ARB_fragment_program, NV_fragment_program, etc)?*

  RESOLVED: The primary issue is how the interpolated texture coordinate set appears when fragment attribute variables (ARB terminology) or fragment program attribute registers (NV terminology) are accessed.

  When point sprite is enabled and the GL_COORD_REPLACE_ARB state for a given texture unit is GL_TRUE, the texture coordinate set for that texture unit is (s,t,0,1) where the point sprite-overridden s and t are described in the amended Section 3.3 below. The important point is that r and q are forced to 0 and 1, respectively.

  For fragment program extensions, r and q correspond to the z and w components of the respective fragment attribute.

* *How does this extension interact with PolygonMode?*

  RESOLVED: If a polygon is rendered in point mode and POINT_SPRITE_ARB is enabled, its vertices will be rendered as point sprites.

* *How does this extension interact with the point size attenuation functionality in ARB_point_parameters and OpenGL 1.4?*

  RESOLVED: Point sprites sizes are attenuated just like the sizes of non-sprite points.

* *What push/pop attribute bits control the state of this extension?*

  RESOLVED: POINT_BIT for all the state. Also ENABLE_BIT for the POINT_SPRITE_ARB enable.

* *How are point sprites clipped?*

  RESOLVED: Point sprites are transformed as points, and standard point clipping operations are performed. This can cause point sprites that move off the edge of the screen to disappear abruptly, in the same way that regular points do. As with any other primitive, standard per-fragment clipping operations (scissoring, window ownership test) still apply.

New Procedures and Functions

None

New Tokens

Accepted by the <cap> parameter of Enable, Disable, and IsEnabled, by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev, and by the <target> parameter of TexEnvi, TexEnviv, TexEnvf, TexEnvfv, GetTexEnviv, and GetTexEnvfv:

```
    POINT_SPRITE_ARB                               0x8861
```

When the <target> parameter of TexEnvf, TexEnvfv, TexEnvi, TexEnviv, GetTexEnvfv, or GetTexEnviv is POINT_SPRITE_ARB, then the value of <pname> may be:

```
    COORD_REPLACE_ARB                              0x8862
```

When the <target> and <pname> parameters of TexEnvf, TexEnvfv, TexEnvi, or TexEnviv are POINT_SPRITE_ARB and COORD_REPLACE_ARB respectively, then the value of <param> or the value pointed to by <params> may be:

```
    FALSE
    TRUE
```

Additions to Chapter 2 of the OpenGL 1.4 Specification (OpenGL Operation)

None.

Additions to Chapter 3 of the OpenGL 1.4 Specification (Rasterization)

Insert the following paragraphs after the second paragraph of section 3.3 (page 66):

"Point sprites are enabled or disabled by calling Enable or Disable with the symbolic constant POINT_SPRITE_ARB. The default state is for point sprites to be disabled. When point sprites are enabled, the state of the point antialiasing enable is ignored.

The point sprite texture coordinate replacement mode is set with one of the commands

```
  void TexEnv{if}(enum target, enum pname, T param)
  void TexEnv{if}v(enum target, enum pname, const T *params)
```

where target is POINT_SPRITE_ARB and pname is COORD_REPLACE_ARB. The possible values for param are FALSE and TRUE. The default value for each texture unit is for point sprite texture coordinate replacement to be disabled."

Replace the first two sentences of the second paragraph of section 3.3.1 (page 67) with the following:

"The effect of a point width other than 1.0 depends on the state of point antialiasing and point sprites. If antialiasing and point sprites are disabled, ..."

Replace the first sentences of the fourth paragraph of section 3.3.1 (page 68) with the following:

"If antialiasing is enabled and point sprites are disabled, ..."

Insert the following paragraphs at the end of section 3.3.1 (page 70):

"When point sprites are enabled, then point rasterization produces a fragment for each framebuffer pixel whose center lies inside a square centered at the point's (x_w, y_w), with side length equal to the current point size.

All fragments produced in rasterizing a point sprite are assigned the same associated data, which are those of the vertex corresponding to the point, with texture coordinates s, t, and r replaced with s/q, t/q, and r/q, respectively. If q is less than or equal to zero, the results are undefined. However, for each texture unit where COORD_REPLACE_ARB is TRUE, these texture coordinates are replaced with point sprite texture coordinates. The s coordinate varies from 0 to 1 across the point horizontally left-to-right, while the t coordinate varies from 0 to 1 vertically top-to-bottom. The r and q coordinates are replaced with the constants 0 and 1, respectively.

The following formula is used to evaluate the s and t coordinates:

```
  s = 1/2 + (x_f + 1/2 - x_w) / size
  t = 1/2 - (y_f + 1/2 - y_w) / size
```

where size is the point's size, x_f and y_f are the (integral) window coordinates of the fragment, and x_w and y_w are the exact, unrounded window coordinates of the vertex for the point.

The widths supported for point sprites must be a superset of those supported for antialiased points. There is no requirement that these widths must be equally spaced. If an unsupported width is requested, the nearest supported width is used instead."

Replace the text of section 3.3.2 (page 70) with the following:

"The state required to control point rasterization consists of the floating-point point width, three floating-point values specifying the minimum and maximum point size and the point fade threshold size, three floating-point values specifying the distance attenuation coefficients, a bit indicating whether or not antialiasing is enabled, a bit indicating whether or not point sprites are enabled, and a bit for the point sprite texture coordinate replacement mode for each texture unit."

Replace the text of section 3.3.3 (page 70) with the following:

"If MULTISAMPLE is enabled, and the value of SAMPLE_BUFFERS is one, then points are rasterized using the following algorithm, regardless of whether point antialiasing (POINT_SMOOTH) is enabled or disabled. Point rasterization produces a fragment for each framebuffer pixel with one or more sample points that intersect a region centered at the point's (x_w, y_w). This region is a circle having diameter equal to the current point width if POINT_SPRITE_ARB is disabled, or a square with side equal to the current point width if POINT_SPRITE_ARB is enabled. Coverage bits that correspond to sample points that intersect the region are 1, other coverage bits are 0. All data associated with each sample for the fragment are the data associated with the point being rasterized, with the exception of texture coordinates when POINT_SPRITE_ARB is enabled; these texture coordinates are computed as described in section 3.3.

Point size range and number of gradations are equivalent to those supported for antialiased points when POINT_SPRITE_ARB is disabled. The set of point sizes supported is equivalent to those for point sprites without multisample when POINT_SPRITE_ARB is enabled."

Interactions with NV_point_sprite

ARB_point_sprite is a functional subset of NV_point_sprite.

The only functional difference between the extensions is that NV_point_sprite provides the POINT_SPRITE_R_MODE_NV control. This mode allows applications to specify how the r texture coordinates for point sprites are replaced. The r coordinate can be replaced with the corresponding s texture coordinate ("S" mode), left unchanged ("R" mode), or replaced with the constant zero ("ZERO" mode). ARB_point_sprite always replaces r texture coordiantes of point sprites with zero.

Since ARB_point_sprite is functionally compatible with the default r mode from NV_point_sprite, the two extensions can coexist nicely. Enumerant values from NV_point_sprite are reused.

If NV_point_sprite is supported, the language describing the replacement of r coordinates for point sprites (forced to zero) is replaced with the corresponding language from NV_point_sprite (controlled by POINT_SPRITE_R_MODE_NV).

Errors

Contact

    Brian Paul (brian_e_paul 'at' yahoo.com)

Status

    Complete. Approved by ARB on February 14, 2002.

Version

    Last Modified Date: 21 January 2002

Number

    ARB Extension #23

Dependencies

    OpenGL 1.1 is required.
    ARB_depth_texture is required.
    This extension is written against the OpenGL 1.3 Specification.

Overview

    This extension clarifies the GL_SGIX_shadow extension.

    This extension supports comparing the texture R coordinate to a depth
    texture value in order to produce a boolean texture value. This can
    be used to implement shadow maps.

    The extension is written in generic terms such that other texture
    comparison modes can be accommodated in the future.

IP Status

    XXX None?

Issues

(1) How is this extension different from GL_SGIX_shadow?

      - It defines GL behaviour when the currently bound texture is not
        a depth texture.
      - It specifies that R is clamped to [0,1].
      - We use the standard GL_LEQUAL and GL_GEQUAL tokens instead of
        defining new ones.
      - The result may be ALPHA, LUMINANCE or INTENSITY.
      - A bit more is said about how depth textures are sampled.
      - The extension is generalized for comparison modes.

```
    (2) Should we use GL_LEQUAL and GL_EQUAL instead of
      GL_TEXTURE_LEQUAL_R_SGIX and GL_TEXTURE_GEQUAL_R_SGIX?

      RESOLUTION: Yes.  The old tokens are misleading.  For example,
      the GL_TEXTURE_LEQUAL_R_SGIX token should really have been named
      GL_R_LEQUAL_TEXTURE_SGIX since we're comparing R <= TEXTURE.
      This extension uses the standard GL_LEQUAL and GL_GEQUAL tokens.
      Also, the original shadow spec seems to be inconsistant with
      what was really implemented in hardware.

    (3) Use TEXTURE_COMPARE_OPERATOR_ARB or TEXTURE_COMPARE_FUNC_ARB?

      RESOLVED: Use TEXTURE_COMPARE_FUNC_ARB to be more consistant with
      the conventions of glDepthFunc(), glStencilFunc(), etc which use
      the GL_LEQUAL, GL_GEQUAL, etc tokens.

    (4) Should the result of the texture comparison be a LUMINANCE,
      INTENSITY or ALPHA texel?

      RESOLVED: Allow any of them. This is controlled by
      DEPTH_TEXTURE_MODE_ARB defined in ARB_depth_texture extension.

    (5) What if TEXTURE_COMPARE_MODE_ARB is set to COMPARE_R_TO_TEXTURE
      but the the currently bound texture is not a depth texture?

      RESOLVED: If the currently bound texture is a color (or paletted
      or color index) texture then the texture unit treats it in the
      usual manner and all texture comparison logic is bypassed.

    (6) Should the R value be clamped to [0,1] before the comparison?

      RESOLUTION: Yes, that makes sense since the depth texels are in
      the range [0,1].  Note that clamping R to [0,1] really only matters
      at the values 0 and 1.

    (7) How is bilinear or trilinear filtering implemented?

      RESOLUTION: We suggest an implementation behaviour but leave the
      details up to the implementation.  Differences here amount to the
      quality and softness of shadow edges.  Specific filtering
      algorithms could be expressed via layered extensions.  We're
      intentionally vague here to avoid IP and patent issues.

    (8) Is GL_ARB_shadow the right name for this extension?

      RESOLVED: Probably.  While this extension is expressed in rather
      generic terms which may be used by future extensions, it implements
      a rather specific operation at this time.

    (9) What about GL_SGIX_shadow_ambient?

      RESOLUTION: Omit that functionality.  It can be accomplished with
      advanced texture extensions such as GL_NV_register_combiners.
      GL_SGIX_shadow_ambient usually can't be implemented with existing
      hardware so it'll be offered as GL_ARB_shadow_ambient, rather than
      burdon this extension with it.

COMPARE_R_TO_TEXTURE_ARB	0x884E

Additions to Chapter 2 of the 1.3 Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the 1.3 Specification (Rasterization)

    Section 3.8.4, Texture Parameters, p. 133, append table 3.19 with the
    following:

Name	Type	Legal Values
TEXTURE_COMPARE_MODE_ARB	enum	NONE, COMPARE_R_TO_TEXTURE
TEXTURE_COMPARE_FUNC_ARB	enum	LEQUAL, GEQUAL

    After section 3.8.12, Texture Environments and Texture Functions,
    p. 149, insert the following new sections (and renumber subsequent
    sections):

"3.8.13 Texture Comparison Modes

    TEXTURE_COMPARE_MODE_ARB can be used to compute the texture value
    according to a comparison function. TEXTURE_COMPARE_MODE_ARB
    specifies the comparison operands, and TEXTURE_COMPARE_FUNC_ARB
    specifies the comparison function. The format of the resulting
    texture sample is specified by the DEPTH_TEXTURE_MODE_ARB.

3.8.13.1 Depth Texture Comparison Mode

    If the currently bound texture's format is DEPTH_COMPONENT then
    TEXTURE_COMPARE_MODE_ARB, TEXTURE_COMPARE_FUNC_ARB and
    DEPTH_TEXTURE_MODE_ARB control the output of the texture unit
    as described below. However, if the currently bound texture is
    not DEPTH_COMPONENT then the texture unit operates in the normal
    manner and texture comparison is bypassed.

    Let Dt (D subscript t) be the depth texture value, in the range
    [0, 1]. Let R be the interpolated texture coordinate clamped to

```
        the range [0, 1].  Then the effective texture value Lt, It, or At
        is computed by

        if TEXTURE_COMPARE_MODE_ARB = NONE

            r = Dt

        else if TEXTURE_COMPARE_MODE_ARB = COMPARE_R_TO_TEXTURE_ARB

            if TEXTURE_COMPARE_FUNC_ARB = LEQUAL

                 { 1.0,  if R <= Dt
             r = {
                 { 0.0,  if R > Dt

            else if TEXTURE_COMPARE_FUNC_ARB = GEQUAL

                 { 1.0,  if R >= Dt
             r = {
                 { 0.0,  if R < Dt

            endif

            if DEPTH_TEXTURE_MODE_ARB = LUMINANCE

                Lt = r

            else if DEPTH_TEXTURE_MODE_ARB = INTENSITY

                It = r

            else if DEPTH_TEXTURE_MODE_ARB = ALPHA

                At = r

            endif

        endif

        If TEXTURE_MAG_FILTER is not NEAREST or TEXTURE_MIN_FILTER is
        not NEAREST or NEAREST_MIPMAP_NEAREST then r may be computed by
        comparing more than one depth texture value to the texture R
        coordinate.  The details of this are implementation-dependent
        but r should be a value in the range [0, 1] which is proportional
        to the number of comparison passes or failures.
```

Additions to Chapter 4 of the 1.3 Specification (Per-Fragment Operations and the Frame Buffer)

None

Additions to Chapter 5 of the 1.3 Specification (Special Functions)

None

Additions to Chapter 6 of the 1.3 Specification (State and State Requests)

In section 6.1.3, p. 200, insert the following after the fourth paragraph:

"The texture compare mode and texture compare function may be queried by calling GetTexParameteriv or GetTexParameterfv with <pname> set to TEXTURE_COMPARE_MODE_ARB, or TEXTURE_COMPARE_FUNC_ARB, respectively."

Additions to the GLX Specification

None

Errors

INVALID_ENUM is generated if TexParameter[if] parameter <pname> is TEXTURE_COMPARE_MODE_ARB and parameter <param> is not NONE or COMPARE_R_TO_TEXTURE.

INVALID_ENUM is generated if TexParameter[if] parameter <pname> is TEXTURE_COMPARE_FUNC_ARB and parameter <param> is not LEQUAL or GEQUAL.

New State

In table 6.16, Texture Objects, p. 224, add the following:

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
TEXTURE_COMPARE_MODE_ARB	Z_2	GetTexParameter[if]v	NONE	compare mode	3.8.13	texture
TEXTURE_COMPARE_FUNC_ARB	Z_2	GetTexParameter[if]v	LEQUAL	compare func	3.8.13	texture

New Implementation Dependent State

None

Revision History

```
19 March 2001
    - initial revision
20 March 2001
    - use GL_LEQUAL, GL_GEQUAL tokens
    - removed TEXTURE_COMPARE_FAIL_VALUE_ARB
16 April 2001
    - renamed TEXTURE_COMPARE_OPERATOR_ARB to TEXTURE_COMPARE_FUNC_ARB
    - replace TEXTURE_COMPARE_ARB with TEXTURE_COMPARE_MODE_ARB
22 April 2001
    - added TEXTURE_COMPARE_RESULT
23 April 2001
    - minor tweaks
22 June 2001
    - fixed grammatical errors
16 November 2001
    - Change default value of TEXTURE_COMPARE_MODE_ARB to LUMINANCE.
17 November 2001
    - Resolved issue 5
    - cleaned up new section 3.8.7.1 yet again
12 December 2001
    - rewritten against the OpenGL 1.3 spec
3 January 2002
    - fixed a typo found by Bimal
18 January 2002
    - Since depth textures can now allow ALPHA, INTENSITY, LUMINANCE mode,
      there was no need for TEXTURE_COMPARE_RESULT_ARB.
21 January 2002
    - Fixed error to be INVALID_ENUM instead of INVALID_OPERATION.
```

Name

    ARB_texture_border_clamp

Name Strings

    GL_ARB_texture_border_clamp

Status

    Complete. Approved by the ARB, 20 June 2000

Version

    1.0, 22 June 2000

Number

    ARB Extension #13

Dependencies

    OpenGL 1.0 is required.

    This extension is written against the OpenGL 1.2.1 Specification.

    This extension is based on and intended to replace
    GL_SGIS_texture_border_clamp.

Overview

    The base OpenGL provides clamping such that the texture coordinates are
    limited to exactly the range [0,1]. When a texture coordinate is clamped
    using this algorithm, the texture sampling filter straddles the edge of
    the texture image, taking 1/2 its sample values from within the texture
    image, and the other 1/2 from the texture border. It is sometimes
    desirable for a texture to be clamped to the border color, rather than to
    an average of the border and edge colors.

    This extension defines an additional texture clamping algorithm.
    CLAMP_TO_BORDER_ARB clamps texture coordinates at all mipmap levels such
    that NEAREST and LINEAR filters return only the color of the border
    texels.

IP Status

    No known IP issues.

Issues

    (1) Is this formulation correct for higher-order texture filters
        (e.g., cubic or anisotropic filters)?

       RESOLVED: No. A more appropriate formulation would clamp the texture
       coordinates in texel space.

New Procedures and Functions

None.

New Tokens

Accepted by the <param> parameter of TexParameteri and TexParameterf, and by the <params> parameter of TexParameteriv and TexParameterfv, when their <pname> parameter is TEXTURE_WRAP_S, TEXTURE_WRAP_T, or TEXTURE_WRAP_R:

```
    CLAMP_TO_BORDER_ARB                             0x812D
```

Additions to Chapter 2 of the OpenGL 1.2.1 Specification (OpenGL Operation)

None.

Additions to Chapter 3 of the OpenGL 1.2.1 Specification (Rasterization)

Modify Table 3.17, p. 124, editing only the following lines:

Name	Type	Legal Values
TEXTURE_WRAP_S	integer	CLAMP, CLAMP_TO_EDGE, REPEAT, CLAMP_TO_BORDER_ARB
TEXTURE_WRAP_T	integer	CLAMP, CLAMP_TO_EDGE, REPEAT, CLAMP_TO_BORDER_ARB
TEXTURE_WRAP_R	integer	CLAMP, CLAMP_TO_EDGE, REPEAT, CLAMP_TO_BORDER_ARB

Modify **Section 3.8.4, Texture Wrap Modes**, p.124

(add at the end of the section, p. 125)

CLAMP_TO_BORDER_ARB clamps texture coordinates at all mipmaps such that the texture filter always samples border texels for fragments whose corresponding texture coordinate is sufficiently far outside the range [0,1]. The color returned when clamping is derived only from the border texels of the texture image, or from the constant border color if the texture image does not have a border.

Texture coordinates are clamped to the range [min, max]. The minimum value is defined as

```
    min = -1 / 2N
```

where N is the size (not including borders) of the one-, two-, or three-dimensional texture image in the direction of clamping. The maximum value is defined as

```
    max = 1 - min
```

so that clamping is always symmetric about the [0,1] mapped range of a texture coordinate.

```

Number

    ARB Extension #12

Dependencies

```
    OpenGL 1.1 is required.

    This extension is written against the OpenGL 1.2.1 Specification.

    This extension is written against the GLX Extensions for OpenGL
        Specification (Version 1.3).

    Depends on GL_ARB_texture_cube_map, as cube maps may be stored in
    compressed form.
```

Overview

```
    Compressing texture images can reduce texture memory utilization and
    improve performance when rendering textured primitives.  This extension
    allows OpenGL applications to use compressed texture images by providing:

        (1) A framework upon which extensions providing specific compressed
            image formats can be built.

        (2) A set of generic compressed internal formats that allow
            applications to specify that texture images should be stored in
            compressed form without needing to code for specific compression
            formats.

    An application can define compressed texture images by providing a texture
    image stored in a specific compressed image format.  This extension does
    not define any specific compressed image formats, but it does provide the
    mechanisms necessary to enable other extensions that do.

    An application can also define compressed texture images by providing an
    uncompressed texture image but specifying a compressed internal format.
    In this case, the GL will automatically compress the texture image using
    the appropriate image format.  Compressed internal formats can either be
```

specific (as above) or generic. Generic compressed internal formats are not actual image formats, but are instead mapped into one of the specific compressed formats provided by the GL (or to an uncompressed base internal format if no appropriate compressed format is available). Generic compressed internal formats allow applications to use texture compression without needing to code to any particular compression algorithm. Generic compressed formats allow the use of texture compression across a wide range of platforms with differing compression algorithms and also allow future GL implementations to substitute improved compression methods transparently.

Compressed texture images can be obtained from the GL in uncompressed form by calling GetTexImage and in compressed form by calling GetCompressedTexImageARB. Queried compressed images can be saved and later reused by calling CompressedTexImage[123]DARB. Pre-compressed texture images do not need to be processed by the GL and should significantly improve texture loading performance relative to uncompressed images.

This extension does not define specific compressed image formats (e.g., S3TC, FXT1), nor does it provide means to encode or decode such images. To support images in a specific compressed format, a hardware vendor would:

(1) Provide a new extension defininig specific compressed <internalformat> and <format> tokens for TexImage[123]D, TexSubImage[123]D, CopyTexImage[12]D, CompressedTexImage[123]DARB, CompressedTexSubImage[123]DARB, and GetCompressedTexImageARB calls.

(2) Specify the encoding of compressed images of that specific format.

(3) Specify a method for deriving the size of compressed images of that specific format, using the <internalformat>, <width>, <height>, <depth> parameters, and (if necessary) the compressed image itself.

IP Status

No known intellectual property issues on this general extension.

Specific compression algorithms used to implement this extension (and any other specific texture compression extensions) may be protected and require licensing agreements.

Issues

(1) Should we define additional internal formats that strongly tie an underlying compression algorithm to the format?

RESOLVED: Not here. Explicit compressed formats will be provided by other extensions built on top of this one.

(2) Should we provide additional compression state that gives more control on the level/quality of compression? If so, how?

RESOLVED: Yes, as a hint. Could have also been implemented as a [0.0, 1.0] floating-point TexParameter "quality" state variable (such as the JPEG quality scale found in many apps). This control will affect only the speed (and quality) with which a driver compresses incoming images, but will not affect the compressed image format selected by the driver.

As the spec is currently formulated, the requirement that quality control not affect compression format selection could have been relaxed by loosening the invariance requirements (so that the quality control can affect the choice of internal format). The risk was the potential for subtle mipmap consistency issues if the hint changes.

(3) Most current compression algorithms handle primarily RGB and RGBA images. Does it make sense having generic compressed formats for alpha, intensity, luminance, and luminance-alpha?

RESOLVED: Yes. It is conceivable that some or all of these formats may be compressed. Implementations not having compression algorithms for these formats can simply choose not to compress and use the appropriate base internal format instead.

(4) Full GetTexImage support requires that the renderer decompress the whole image. Should this extra implementation burden be imposed on the renderer?

RESOLVED: Yes, returning the uncompressed image is a useful feature for evaluating the quality of the compressed image. A decompression engine may also be required for a number of other areas, including software rasterization.

(5) Full TexSubImage support may require that the renderer decompress portions of the image (or perhaps the whole image), do a merge, and then recompress. Even if this were done, portions of the image outside the "modified" area may also be modified due to lossy compression. Should this extra implementation burden be imposed on the renderer?

RESOLVED: No. To avoid the complications involved with modifying a compressed texture image, only the lower-left corner may be modified by TexSubImage. In addition, after calling TexSubImage, the "unmodified" portion of the image is left undefined. An INVALID_OPERATION error results from any other TexSubImage calls.

This behavior allows for the use of compressed images whose dimensions are not powers of two, which TexImage will not accept. The recommended sequence of calls for defining such images is to first call TexImage with a NULL <data> pointer and the image size parameters padded out to the next power of two, and then call CompressedTexSubImageARB or TexSubImage with <xoffset>, <yoffset>, and <zoffset> parameters of zero and the compressed data pointed to by <data>. This behavior also allows TexSubImage to be used as a light-weight replacement of TexImage, where only the image contents are modified.

Certain compressed formats may allow a wider variety of edits -- their specifications will document the restrictions under which these edits are permitted. it is impossible to document such restrictions for unknown generic formats. It is desirable to keep the behavior of generic formats and the specific formats they map to as consistent as possible.

(6) What do the return values of the component sizes (RED_BITS, GREEN_BITS, ...) give for compressed textures? Compressed proxy textures?

RESOLVED: Some behavior has to be defined. For both normal and proxy textures, we return the bit depths of an uncompressed sized image that would most closely match the quality of the compression algorithm for an "average" texture image. Since compressed image quality is highly data dependent, the actual compressed image quality may be better or worse than the renderer's best guess at the best matching sized internal format. To implement this feature in a driver, it is expected that an error analysis would be done on a set of representative images, and the resultant "equivalent bit depths" would be hardwired constants.

(7) What should GetTexLevelParameter with TEXTURE_COMPRESSED_ IMAGE_SIZE_ARB return for existing uncompressed formats? For proxy textures?

RESOLVED: For both, an INVALID_OPERATION error results. The actual image to be compressed is not available for proxies, so actually compressing the specified image is not an option.

For uncompressed internal formats, we could return the actual amount of memory taken by the texture image. Such a mechanism might be useful as a metric of "how much space does this texture image take". It's not particularly useful for an application based texture management scheme, since there is no information available indicating the amount of available memory. In addition, because of implementation-dependent hardware constraints, the amount of texture memory consumed by a texture object is not necessarily equal to the sum of the memory consumed by each of its mipmaps. The OpenGL ARB decided against adopting this behavior when this specification was approved.

(8) What about texture borders?

RESOLVED: Not a problem for generic compressed formats since a base internal format can be used if borders are not supported in the compressed image format. Borders may pose problems for specific compression extensions, and compressed textures with borders might well be disallowed by those extensions.

(9) Should certain pixel operations be disallowed for compressed texture internal formats (e.g., PixelStorage, PixelTransfer)? What about byte swapping?

RESOLVED: For uncompressed source images, all pixel storage and pixel transfer modes will be applied prior to compression. For compressed source images, all pixel storage and transfer modes will be ignored. The encoding of compressed images should be specified as a byte stream that matches the disk file format defined for the corresponding image type.

(10) Should functionality be provided to allow applications to save compressed images to disk and reuse them in subsequent runs without programming to specific formats? If so, how?

RESOLVED: Yes. This can be done without knowledge of specific compression formats in the following manner:

* Call TexImage with an uncompressed image and a generic compressed internal format. The texture image will be compressed by the GL, if possible.

* Call GetTexLevelParameteriv with a <value> of TEXTURE_COMPRESSED_ARB to determine if the GL was able to store the image in compressed form.

* Call GetTexLevelParameteriv with a <value> of TEXTURE_INTERNAL_FORMAT to determine the specific compressed image format in which the image is stored.

* Call GetTexLevelParameteriv with a <value> of TEXTURE_COMPRESSED_IMAGE_SIZE_ARB to determine the size (in ubytes) of the compressed image that will be returned by the GL. Allocate a buffer of at least this size.

* Call GetCompressedTexImageARB. The GL will write the compressed texture image into the allocated buffer.

* Save the returned compressed image to disk, along with the associated width, height, depth, border parameters and the returned values of TEXTURE_COMPRESSED_IMAGE_SIZE_ARB and TEXTURE_INTERNAL_FORMAT.

* Load the compressed image and its parameters, and call CompressedTexImage_[123]DARB to use the compressed image. The value of TEXTURE_INTERNAL_FORMAT should be used as <internalFormat> and the value of TEXTURE_COMPRESSED_IMAGE_SIZE_ARB should be used as <imageSize>.

The saved images will be valid as long as they are used on a device supporting the returned <internalFormat> parameter. If the saved images are used on a device that does not support the compressed internal format, an INVALID_ENUM error would be generated by the call to CompressedTexImage_[123]D because of the unknown format.

Note also that to reliably determine if the GL will compress an image without actually compressing it, an application need only define a proxy texture image and query TEXTURE_COMPRESSED_ARB as above.

(11) Without knowing of the compressed image format, there is no convenient way for the client-side GLX library or tracing tools to ascertain the size of a compressed texture image when sending a TexImage1D, TexImage2D, or TexImage3D packet or interpret pixel storage modes. To complicate matters further, it is possible to create both indirect (that might not understand an image format) and direct rendering contexts (that might understand an image format) on the same renderer. How should this be solved?

RESOLVED: A separate set of CompressedTexImage and CompressedTexSubImage calls has been created that allows libraries to pass compressed images along to the renderer without needing to understand their specific image formats or how to interpret pixel storage modes.

(12) Are the CompressedTexImage[123]DARB entry points really needed?

RESOLVED: Yes. To robustly support images of unknown format, specific compressed entry points are required. While the extension does not support images in a completely unspecified format (early drafts did), having a separate call means that GLX and tools such as GLS (stream encoder) do not need intimate knowledge of every compressed image format. Having separate calls also cleanly solves the problem where pixel storage and pixel transfer operations apply if and only if the source image is uncompressed.

(13) Is variable-ratio compression supported?

RESOLVED: Yes. Fixed-ratio compression is currently the predominant texture compression format, but this spec should not preclude the use of other compression schemes.

(14) Should the <imageSize> parameter be validated on CompressedTexImage calls?

RESOLVED: Yes. Enforcement overhead is generally trivial. Without enforcement, an application could specify incorrect image sizes but notice them only when run on an indirect renderer, causing portability problems. There is also a reliability issue with respect to the GLX environment -- if the compressed image size provided by the user is less than the required image size, the GLX server may run off the end of the image and access invalid memory. A size check may thus be desirable to prevent server crashes (even though that could be considered an "undefined" result).

While enforcing correct <imageSize> parameters is trivial for current compressed internal formats, it might not be reasonable on others (particular variable-ratio compression formats). For such formats, this restriction should be overridden in the spec defining the formats. The <imageSize> check was made mandatory only in the final draft approved at the March 2000 OpenGL ARB meeting.

(15) Should TexImage calls fall back to uncompressed image formats when <internalformat> is a specific compressed format but its use in combination with other parameter values passed is not supported by the renderer?

RESOLVED: Yes. Advantages: Works in exactly the same way as generic formats, meaning no extra code/error checking. Inherent limitations of TexImage on specific formats should be documented in their specs and observed by their users. One simple query can detect fallback cases. Disadvantages: Silent fallback to a format not requested by the user.

(16) Should the texture format invariance requirements disallow scanning of the image data to select a compression method? What about for a base (uncompressed) internal format?

RESOLVED: The primary issue is mipmap consistency. The 1.2.1 spec defines a set of mipmaps as consistent if all are specified using the same internal format. However, it doesn't require that all mipmaps are allocated using the same format -- the renderer is responsible for ensuring mipmap consistency if it selects different formats for different images. There is no reason to disallow scanning for base internal formats; the renderer is responsible for doing the right thing.

The selection of a specific compressed internal format is different. It must be independent of the the image data because the GL treats the texture image as though it were specified using the specific compressed internal format chosen by the renderer.

(17) Should functionality be provided to enumerate the specific compressed formats supported by the renderer? If so, how and what will it accomplish?

RESOLVED: Yes. A glGet* query is added to return the number of compressed internal formats supported by the renderer and the <internalformat> tokens for each. These tokens can subsequently be used as <internalformat> parameters for normal TexImage calls and the new CompressedTexImage calls.

Providing an internal format enumeration allows applications to weigh the suitability of the various compression methods provided to it by the renderer without needing specific knowledge of the formats. Applications can query the component sizes (see issue 6) to determine the base format and approximate precision. Applications can directly evaluate image compression quality by having the renderer generate compressed texture images (using the returned <internalformat> values) and return them in uncompressed form using GetTexImage. Applications should also be aware that the use of the internal formats returned by this query is subject to the restrictions imposed by the specification defining them. The use of proxy textures allows the application to determine if a specific set of TexImage parameters is supported for a given internal format.

The renderer should enumerate all supported compression formats EXCEPT those that operate fundamentally differently from a normal uncompressed format. For example, the DirectX DXT1 compression format is fundamentally an RGB format, but it has a "transparent" encoding where the red, green, and blue component values are forced to zero, regardless of their original (uncompressed) values. Since such formats may have caveats that must be understood before being used, they should not be enumerated by this query.

This allows for forward compatibility -- an application can exploit compression techniques provided by future renderers.

(18) Should the separate GetCompressedTexImageARB function exist, or is GetTexImage with special <format> and/or <type> parameters sufficient?

RESOLVED: Provide a separate GetCompressedTexImageARB function. The primary rationale is for GLX indirect rendering. The client GetTexImage would require information to determine if an image is uncompressed (and should be decoded using pixel storage state) or compressed (pixel storage ignored). In addition, if the image is compressed, the actual image size would be required, but the only image size that could be inferred from the GLX protocol is padded out to a multiple of four bytes. A separate call is the cleanest solution to both issues.

New Procedures and Functions

```
    void CompressedTexImage3DARB(enum target, int level,
                                 enum internalformat, sizei width,
                                 sizei height, sizei depth,
                                 int border, sizei imageSize,
                                 const void *data);
    void CompressedTexImage2DARB(enum target, int level,
                                 enum internalformat, sizei width,
                                 sizei height, int border,
                                 sizei imageSize, const void *data);
    void CompressedTexImage1DARB(enum target, int level,
                                 enum internalformat, sizei width,
                                 int border, sizei imageSize,
                                 const void *data);
    void CompressedTexSubImage3DARB(enum target, int level,
                                    int xoffset, int yoffset,
                                    int zoffset, sizei width,
                                    sizei height, sizei depth,
                                    enum format, sizei imageSize,
                                    const void *data);
    void CompressedTexSubImage2DARB(enum target, int level,
                                    int xoffset, int yoffset,
                                    sizei width, sizei height,
                                    enum format, sizei imageSize,
                                    const void *data);
    void CompressedTexSubImage1DARB(enum target, int level,
                                    int xoffset, sizei width,
                                    enum format, sizei imageSize,
                                    const void *data);
    void GetCompressedTexImageARB(enum target, int lod,
                                  void *img);
```

New Tokens

```
    Accepted by the <internalformat> parameter of TexImage1D, TexImage2D,
    TexImage3D, CopyTexImage1D, and CopyTexImage2D:

        COMPRESSED_ALPHA_ARB                            0x84E9
        COMPRESSED_LUMINANCE_ARB                        0x84EA
        COMPRESSED_LUMINANCE_ALPHA_ARB                  0x84EB
        COMPRESSED_INTENSITY_ARB                        0x84EC
        COMPRESSED_RGB_ARB                              0x84ED
        COMPRESSED_RGBA_ARB                             0x84EE

    Accepted by the <target> parameter of Hint and the <value> parameter of
    GetIntegerv, GetBooleanv, GetFloatv, and GetDoublev:

        TEXTURE_COMPRESSION_HINT_ARB                    0x84EF

    Accepted by the <value> parameter of GetTexLevelParameter:

        TEXTURE_COMPRESSED_IMAGE_SIZE_ARB               0x86A0
        TEXTURE_COMPRESSED_ARB                          0x86A1
```

Accepted by the <value> parameter of GetIntegerv, GetBooleanv, GetFloatv, and GetDoublev:

```
    NUM_COMPRESSED_TEXTURE_FORMATS_ARB              0x86A2
    COMPRESSED_TEXTURE_FORMATS_ARB                  0x86A3
```

Additions to Chapter 2 of the OpenGL 1.2.1 Specification (OpenGL Operation)

None.

Additions to Chapter 3 of the OpenGL 1.2.1 Specification (Rasterization)

Modify **Section 3.8.1, Texture Image Specification (p.113)**

(p.113, modify 3rd paragraph) <internalformat> may be specified as one of the six base internal format symbolic constants listed in table 3.15, as one of the sized internal format symbolic constants listed in table 3.16, as one of the specific compressed internal format symbolic constants listed in table 3.16.1, or as one of the six generic compressed internal format symbolic constants listed in table 3.16.2.

(p.113, add after 3rd paragraph)

The ARB_texture_compression specification provides no specific compressed internal formats but does provide a mechanism to obtain the enums for such formats provided by other specifications. If the ARB_texture_compression extension is supported, the number of specific compressed internal format symbolic constants supported by the renderer can be obtained by querying the value of NUM_COMPRESSED_TEXTURE_FORMATS_ARB. The set of specific compressed internal format symbolic constants supported by the renderer can be obtained by querying the value of COMPRESSED_TEXTURE_FORMATS_ARB. The only symbolic constants returned by this query are those suitable for general-purpose usage. The renderer will not enumerate formats with restrictions that need to be specifically understood prior to use.

Generic compressed internal formats are never used directly as the internal formats of texture images. If <internalformat> is one of the six generic compressed internal formats, its value is replaced by the symbolic constant for a specific compressed internal format of the GL's choosing with the same base internal format. If no specific compressed format is available, <internalformat> is instead replaced by the corresponding base internal format. If <internalformat> is given as or mapped to a specific compressed internal format, but the GL can not support images compressed in the chosen internal format for any reason (e.g., the compression format might not support 3D textures or borders), <internalformat> is replaced by the corresponding base internal format and the texture image will not be compressed by the GL.

(p.113, modify 4th paragraph) ... If a compressed internal format is specified, the mapping of the R, G, B, and A values to texture components is equivalent to the mapping of the corresponding base internal format's components, as specified in table 3.15. The specified image is compressed using a (possibly lossy) compression algorithm chosen by the GL.

(p.113, 5th paragraph) A GL implementation may vary its allocation of internal component resolution or compressed internal format based on any TexImage3D, TexImage2D, or TexImage1D (see below) parameter (except

<target>, but the allocation and chosen compressed image format must not be a function of any other state and cannot be changed once they are established. In addition, the choice of a compressed image format may not be affected by the <data> parameter. Allocations must be invariant; the same allocation and compressed image format must be chosen each time a texture image is specified with the same parameter values. These allocation rules also apply to proxy textures, which are described in section 3.8.7.

Add Table 3.16.1: Specific Compressed Internal Formats

Compressed Internal Format	Base Internal Format
none provided here -- defined by dependent extensions	

Add Table 3.16.2: Generic Compressed Internal Formats

Generic Compressed Internal Format	Base Internal Format
COMPRESSED_ALPHA_ARB	ALPHA
COMPRESSED_LUMINANCE_ARB	LUMINANCE
COMPRESSED_LUMINANCE_ALPHA_ARB	LUMINANCE_ALPHA
COMPRESSED_INTENSITY_ARB	INTENSITY
COMPRESSED_RGB_ARB	RGB
COMPRESSED_RGBA_ARB	RGBA

Modify **Section 3.8.2, Alternate Image Specification**

(add to end of TexSubImage discussion, p.123)

Texture images with compressed internal formats may be stored in such a way that it is not possible to edit an image with subimage commands without having to decompress and recompress the texture image being edited. Even if the image were edited in this manner, it may not be possible to preserve the contents of some of the texels outside the region being modified. To avoid these complications, the GL does not support arbitrary edits to texture images with compressed internal formats. Calling TexSubImage3D, CopyTexSubImage3D, TexSubImage2D, CopyTexSubImage2D, TexSubImage1D, or CopyTexSubImage1D will result in an INVALID_OPERATION error if <xoffset>, <yoffset>, or <zoffset> is not equal to -b_s (border). In addition, the contents of any texel outside the region modified by such a call are undefined. These restrictions may be relaxed for specific compressed internal formats whose images are easily edited.

(add new subsection at end of section, p.123)

Compressed Texture Images

Texture images may also be specified or modified using image data already stored in a known compressed image format. The ARB_texture_compression extension defines no such formats, but provides the mechanisms for other extensions that do.

The commands

```
  void CompressedTexImage1DARB(enum target, int level,
                               enum internalformat, sizei width,
                               int border, sizei imageSize,
                               const void *data);
  void CompressedTexImage2DARB(enum target, int level,
                               enum internalformat, sizei width,
                               sizei height, int border,
                               sizei imageSize, const void *data);
  void CompressedTexImage3DARB(enum target, int level,
                               enum internalformat, sizei width,
                               sizei height, sizei depth,
                               int border, sizei imageSize,
                               const void *data);
```

define one-, two-, and three-dimensional texture images, respectively, with incoming data stored in a specific compressed image format. The <target>, <level>, <internalformat>, <width>, <height>, <depth>, and <border> parameters have the same meaning as in TexImage1D, TexImage2D, and TexImage3D. <data> points to compressed image data stored in the compressed image format corresponding to <internalformat>. Since this extension provides no specific image formats, using any of the six generic compressed internal formats as <internalformat> will result in an INVALID_ENUM error.

For all other compressed internal formats, the compressed image will be decoded according to the specification defining the <internalformat> token. Compressed texture images are treated as an array of <imageSize> ubytes beginning at address <data>. All pixel storage and pixel transfer modes are ignored when decoding a compressed texture image. If the <imageSize> parameter is not consistent with the format, dimensions, and contents of the compressed image, an INVALID_VALUE error results. If the compressed image is not encoded according to the defined image format, the results of the call are undefined.

Specific compressed internal formats may impose format-specific restrictions on the use of the compressed image specification calls or parameters. For example, the compressed image format might be supported only for 2D textures or may not allow non-zero <border> values. Any such restrictions will be documented in the specification defining the compressed internal format; violating these restrictions will result in an INVALID_OPERATION error.

Any restrictions imposed by specific compressed internal formats will be invariant, meaning that if the GL accepts and stores a texture image in compressed form, providing the same image to CompressedTexImage1DARB, CompressedTexImage2DARB, CompressedTexImage3DARB will not result in an INVALID_OPERATION error if the following restrictions are satisfied:

* <data> points to a compressed texture image returned by GetCompressedTexImageARB (Section 6.1.4).

* <target>, <level>, and <internalformat> match the <target>, <level> and <format> parameters provided to the GetCompressedTexImageARB call returning <data>.

* <width>, <height>, <depth>, <border>, <internalformat>, and
  <imageSize> match the values of TEXTURE_WIDTH, TEXTURE_HEIGHT,
  TEXTURE_DEPTH, TEXTURE_BORDER, TEXTURE_INTERNAL_FORMAT, and
  TEXTURE_COMPRESSED_IMAGE_SIZE_ARB for image level <level> in effect at
  the time of the GetCompressedTexImageARB call returning <data>.

This guarantee applies not just to images returned by
GetCompressedTexImageARB, but also to any other properly encoded
compressed texture image of the same size and format.

The commands

```
  void CompressedTexSubImage1DARB(enum target, int level,
                                  int xoffset, sizei width,
                                  enum format, sizei imageSize,
                                  const void *data);
  void CompressedTexSubImage2DARB(enum target, int level,
                                  int xoffset, int yoffset,
                                  sizei width, sizei height,
                                  enum format, sizei imageSize,
                                  const void *data);
  void CompressedTexSubImage3DARB(enum target, int level,
                                  int xoffset, int yoffset,
                                  int zoffset, sizei width,
                                  sizei height, sizei depth,
                                  enum format, sizei imageSize,
                                  const void *data);
```

respecify only a rectangular region of an existing texture array, with
incoming data stored in a known compressed image format. The <target>,
<level>, <xoffset>, <yoffset>, <zoffset>, <width>, <height>, and <depth>
parameters have the same meaning as in TexSubImage1D, TexSubImage2D, and
TexSubImage3D. <data> points to compressed image data stored in the
compressed image format corresponding to <format>. Since this extension
provides no specific image formats, using any of these six generic
compressed internal formats as <format> will result in an INVALID_ENUM
error.

The image pointed to by <data> and the <imageSize> parameter are
interpreted as though they were provided to CompressedTexImage1DARB,
CompressedTexImage2DARB, and CompressedTexImage3DARB. These commands do
not provide for image format conversion, so an INVALID_OPERATION error
results if <format> does not match the internal format of the texture
image being modified. If the <imageSize> parameter is not consistent with
the format, dimensions, and contents of the compressed image (too little
or too much data), an INVALID_VALUE error results.

As with CompressedTexImage calls, compressed internal formats may have
additional restrictions on the use of the compressed image specification
calls or parameters. Any such restrictions will be documented in the
specification defining the compressed internal format; violating these
restrictions will result in an INVALID_OPERATION error.

Any restrictions imposed by specific compressed internal formats will be
invariant, meaning that if the GL accepts and stores a texture image in

compressed form, providing the same image to CompressedTexSubImage1DARB, CompressedTexSubImage2DARB, CompressedTexSubImage3DARB will not result in an INVALID_OPERATION error if the following restrictions are satisfied:

* <data> points to a compressed texture image returned by GetCompressedTexImageARB (Section 6.1.4).

* <target>, <level>, and <format> match the <target>, <level> and <format> parameters provided to the GetCompressedTexImageARB call returning <data>.

* <width>, <height>, <depth>, <format>, and <imageSize> match the values of TEXTURE_WIDTH, TEXTURE_HEIGHT, TEXTURE_DEPTH, TEXTURE_INTERNAL_FORMAT, and TEXTURE_COMPRESSED_IMAGE_SIZE_ARB for image level <level> in effect at the time of the GetCompressedTexImageARB call returning <data>.

* <width>, <height>, <depth>, <format> match the values of TEXTURE_WIDTH, TEXTURE_HEIGHT, TEXTURE_DEPTH, and TEXTURE_INTERNAL_FORMAT currently in effect for image level <level>.

* <xoffset>, <yoffset>, and <zoffset> are all "-<b>", where <b> is the value of TEXTURE_BORDER currently in effect for image level <level>.

This guarantee applies not just to images returned by GetCompressedTexImageARB, but also to any other properly encoded compressed texture image of the same size.

Calling CompressedTexSubImage3D, CompressedTexSubImage2D, or CompressedTexSubImage1D will result in an INVALID_OPERATION error if <xoffset>, <yoffset>, or <zoffset> is not equal to -b_s (border), or if <width>, <height>, and <depth> do not match the values of TEXTURE_WIDTH, TEXTURE_HEIGHT, or TEXTURE_DEPTH, respectively. The contents of any texel outside the region modified by the call are undefined. These restrictions may be relaxed for specific compressed internal formats whose images are easily edited.

Additions to Chapter 4 of the OpenGL 1.2.1 Specification (Per-Fragment Operations and the Frame Buffer)

None.

Additions to Chapter 5 of the OpenGL 1.2.1 Specification (Special Functions)

Modify **Section 5.6, Hints** (p.180)

(p.180, modify first paragraph)

...; FOG_HINT, indicating whether fog calculations are done per pixel or per vertex; and TEXTURE_COMPRESSION_HINT_ARB, indicating the desired quality and performance of compressing texture images.

For the texture compression hint, a <hint> of FASTEST indicates that texture images should be compressed as quickly as possible, while NICEST indicates that the texture images be compressed with as little image degradation as possible. FASTEST should be used for one-time texture compression, and NICEST should be used if the compression results are to be retrieved by GetCompressedTexImageARB (Section 6.1.4) for reuse.

Additions to Chapter 6 of the OpenGL 1.2.1 Specification (State and State Requests)

Modify **Section 6.1.3, Enumerated Queries** (p.183)

(p.183, modify next-to-last paragraph)

For texture images with uncompressed internal formats, queries of TEXTURE_RED_SIZE, TEXTURE_GREEN_SIZE, TEXTURE_BLUE_SIZE, TEXTURE_ALPHA_SIZE, TEXTURE_LUMINANCE_SIZE, and TEXTURE_INTENSITY_SIZE return the actual resolutions of the stored image array components, not the resolutions specified when the image array was defined. For texture images with a compressed internal format, the resolutions returned specify the component resolution of an uncompressed internal format that produces an image of roughly the same quality as the compressed image in question. Since the quality of the implementation's compression algorithm is likely data-dependent, the returned component sizes should be treated only as rough approximations. ...

(p.183, add to end of next-to-last paragraph)

TEXTURE_COMPRESSED_IMAGE_SIZE_ARB returns the size (in ubytes) of the compressed texture image that would be returned by GetCompressedTexImageARB (Section 6.1.4). Querying TEXTURE_COMPRESSED_IMAGE_SIZE_ARB is not allowed on texture images with an uncompressed internal format or on proxy targets and will result in an INVALID_OPERATION error if attempted.

Modify **Section 6.1.4, Texture Queries** (p.184)

(add immediately after the GetTexImage section and before the IsTexture section)

The command

```
  void GetCompressedTexImageARB(enum target, int lod,
                                void *img);
```

is used to obtain texture images stored in compressed form. The parameters <target>, <lod>, and <img> are interpreted in the same manner as in GetTexImage. When called, GetCompressedTexImageARB writes TEXTURE_COMPRESSED_IMAGE_SIZE_ARB ubytes of compressed image data to the memory pointed to by <img>. The compressed image data is formatted according to the specification defining INTERNAL_FORMAT. All pixel storage and pixel transfer modes are ignored when returning a compressed texture image.

Calling GetCompressedTexImageARB with an <lod> value less than zero or greater than the maximum allowable causes an INVALID_VALUE error. Calling GetCompressedTexImageARB with a texture image stored with an uncompressed internal format causes an INVALID_OPERATION error.

Additions to Appendix A of the OpenGL 1.2.1 Specification (Invariance)

None.

Additions to the AGL/GLX/WGL Specifications

None.

GLX Protocol

(Add after GetTexImage to Section 2.2.2 of the GLX 1.3 encoding spec, p.74)

GetCompressedTexImageARB

```
    1       CARD8               opcode (X assigned)
    1       160                 GLX opcode
    2       4                   request length
    4       GLX_CONTEXT_TAG     context tag
    4       ENUM                target
    4       INT32               level

 -->

    1       1                   Reply
    1       1                   unused
    2       CARD16              sequence number
    4       n                   reply length
    8                           unused
    4       INT32               compressed image size (in bytes) --
                                  should be between 4n-3 and 4n
    12                          unused
    4*n     LISTofBYTE          teximage
```

Note that n may be zero, indicating that a GL error occurred.

Since pixel storage modes do not apply to compressed texture images, teximage is simply an array of bytes. The client library will ignore pixel storage modes and should copy only <compressed image size> bytes, regardless of the value of <reply length>.

```
(Add to end of Section 2.3 of the GLX 1.3 encoding spec, p.147)
```

CompressedTexImage1DARB

```
    2       32+n+p          rendering command length
    2       214             rendering command opcode
    4       ENUM            target
    4       INT32           level
    4       ENUM            internalformat
    4       INT32           width
    4                       unused

        p                       unused, p=pad(n)

    If the command is encoded in a glXRenderLarge request, the command
    opcode and command length fields are expanded to 4 bytes each.

        4       40+n+p          rendering command length
        4       218             rendering command opcode

    CompressedTexSubImage3DARB

        2       44+n+p          rendering command length
        2       219             rendering command opcode
        4       ENUM            target
        4       INT32           level
        4       INT32           xoffset
        4       INT32           yoffset
        4       INT32           zoffset
        4       INT32           width
        4       INT32           height
        4       INT32           depth
        4       ENUM            format
        4       INT32           imageSize
        n       LISTofBYTE      image
        p                       unused, p=pad(n)

    If the command is encoded in a glXRenderLarge request, the command
    opcode and command length fields are expanded to 4 bytes each.

        4       48+n+p          rendering command length
        4       219             rendering command opcode
```

Errors

```
    Errors for compressed TexImage and TexSubImage calls specific to
    compression:

    INVALID_OPERATION is generated by TexSubImage1D, TexSubImage2D,
    TexSubImage3D, CopyTexSubImage1D, CopyTexSubImage2D, or CopyTexSubImage3D
    if the internal format of the texture image is compressed and <xoffset>,
    <yoffset>, or <zoffset> does not equal -b, where b is value of
    TEXTURE_BORDER.
    INVALID_VALUE is generated by CompressedTexSubImage1DARB,
    CompressedTexSubImage2DARB, or CompressedTexSubImage3DARB if the entire
    texture image is not being edited:  if <xoffset>, <yoffset>, or <zoffset>
    is greater than -b, <xoffset> + <width> is less than w+b, <yoffset> +
    <height> is less than h+b, or <zoffset> + <depth> is less than d+b, where
    b is the value of TEXTURE_BORDER, w is the value of TEXTURE_WIDTH, h is
    the value of TEXTURE_HEIGHT, and d is the value of TEXTURE_DEPTH.

    INVALID_ENUM is generated by CompressedTexImage1DARB,
    CompressedTexImage2DARB, or CompressedTexImage3DARB,
    CompressedTexSubImage1DARB, CompressedTexSubImage2DARB, or
    CompressedTexSubImage3DARB, if <internalformat> is any of the six generic
    compressed internal formats (e.g., COMPRESSED_RGBA_ARB)

    INVALID_OPERATION is generated by CompressedTexImage1DARB,
    CompressedTexImage2DARB, CompressedTexImage3DARB,
    CompressedTexSubImage1DARB, CompressedTexSubImage2DARB, or
    CompressedTexSubImage3DARB, if any parameter combinations are not
    supported by the specific compressed internal format.  Such invalid
    combinations are documented in the specification defining the internal
    format.

    INVALID_VALUE is generated by CompressedTexImage1DARB,
    CompressedTexImage2DARB, or CompressedTexImage3DARB,
    CompressedTexSubImage1DARB, CompressedTexSubImage2DARB, or
    CompressedTexSubImage3DARB, if <imageSize> is not consistent with the
    format, dimensions, and contents of the specified image.  The appropriate
    value for the <imageSize> parameter is documented in the specification
    defining the compressed internal format.

    Undefined results (including abnormal program termination) are generated
    by CompressedTexImage1DARB, CompressedTexImage2DARB, or
    CompressedTexImage3DARB, CompressedTexSubImage1DARB,
    CompressedTexSubImage2DARB, or CompressedTexSubImage3DARB, is not encoded
    in a manner consistent with the specification defining the internal
    format.

    INVALID_OPERATION is generated by CompressedTexSubImage1DARB,
    CompressedTexSubImage2DARB, or CompressedTexSubImage3DARB if <format> does
    not match the internal format of the texture image being modified.

    INVALID_OPERATION is generated by GetTexLevelParameter[if]v if <target> is
    PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, or PROXY_TEXTURE_3D and <value> is
    TEXTURE_COMPRESSED_IMAGE_SIZE_ARB.

    INVALID_OPERATION is generated by GetTexLevelParameter[if]v if the
    internal format of the queried texture image is not compressed and <value>
    is TEXTURE_COMPRESSED_IMAGE_SIZE_ARB.

    INVALID_OPERATION is generated by GetCompressedTexImageARB if the internal
    format of the queried texture image is not compressed.

    Errors for compressed TexImage and TexSubImage calls not specific to
    compression:
```

```
    INVALID_ENUM is generated by CompressedTexImage3DARB or
    CompressedTexSubImage3DARB if <target> is not TEXTURE_3D.

    INVALID_ENUM is generated by CompressedTexImage2DARB or
    CompressedTexSubImage2DARB if <target> is not TEXTURE_2D,
    TEXTURE_CUBE_MAP_POSITIVE_X_ARB, TEXTURE_CUBE_MAP_NEGATIVE_X_ARB,
    TEXTURE_CUBE_MAP_POSITIVE_Y_ARB, TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB,
    TEXTURE_CUBE_MAP_POSITIVE_Z_ARB, or TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB.

    INVALID_ENUM is generated by CompressedTexImage1DARB or
    CompressedTexSubImage1DARB if <target> is not TEXTURE_1D.

    INVALID_VALUE is generated by CompressedTexImage1DARB,
    CompressedTexImage2DARB, CompressedTexImage3DARB,
    CompressedTexSubImage1DARB, CompressedTexSubImage1DARB, or
    CompressedTexSubImage3DARB if <level> is negative.

    INVALID_VALUE is generated by CompressedTexImage1DARB,
    CompressedTexImage2DARB, CompressedTexImage3DARB,
    CompressedTexSubImage1DARB, CompressedTexSubImage2DARB, or
    CompressedTexSubImage3DARB, if <width>, <height>, or <depth> is negative.

    INVALID_VALUE is generated by CompressedTexImage1DARB,
    CompressedTexImage2DARB, or CompressedTexImage3DARB if <width>, <height>,
    or <depth> can not be represented as 2^k+2 for some integer value k.

    INVALID_VALUE is generated by CompressedTexImage1DARB,
    CompressedTexImage2DARB, or CompressedTexImage3DARB if <border> is not
    zero or one.

    INVALID_VALUE is generated by CompressedTexImage1DARB,
    CompressedTexImage2DARB, CompressedTexImage3DARB,
    CompressedTexSubImage1DARB, CompressedTexSubImage1DARB, or
    CompressedTexSubImage3DARB if the call is made between a call to Begin and
    the corresponding call to End.

    INVALID_VALUE is generated by CompressedTexSubImage1DARB,
    CompressedTexSubImage2DARB, or CompressedTexSubImage3DARB if <xoffset>,
    <yoffset>, or <zoffset> is less than -b, <xoffset> + <width> is greater
    than w+b, <yoffset> + <height> is greater than h+b, or <zoffset> + <depth>
    is greater than d+b, where b is the value of TEXTURE_BORDER, w is the
    value of TEXTURE_WIDTH, h is the value of TEXTURE_HEIGHT, and d is the
    value of TEXTURE_DEPTH.

    INVALID_VALUE is generated by GetCompressedTexImageARB if <lod> is
    negative or greater than the maximum allowable level.
```

New State

(table 6.12, p.202)

Revision History

```
    1.03, 05/23/00 prbrown1: Removed stray "None." paragraph in modifications
                             to Chapter 5.

    1.02, 05/08/00 prbrown1: Fixed prototype of GetCompressedTexImageARB (no
                             "const" qualifiers) in "New Procedures and
                             Functions" section.  Changed <internalformat>
                             parameter of CompressedTexImage functions to be
                             an "enum" instead of an "int".  "int" was carried
                             over only on TexImage calls as a 1.0 legacy --
                             the newer CopyTexImage call takes an "enum".

    1.01, 04/11/00 prbrown1: Minor bug fixes to the first published version.
                             Fixed prototypes to match extension spec
                             standards (no "GL" type prefixes).  Fixed a
                             couple erroneous function names.  Added "const"
                             qualifier to prototypes involving image data not
                             modified by the GL.  Added text to indicate that
                             compressed formats apply to texture maps
                             supported by GL_ARB_texture_cube_map.
    1.0,  03/24/00 prbrown1: Applied changes approved as part of the extension
                             at the March 2000 ARB meeting, as follows:

                             * CompressedTexSubImage:  Only allowed if the
                               entire image is replaced.  Document that this
                               restriction can be relaxed for specific
                               compression extensions.
                             * Renamed TEXTURE_IMAGE_SIZE_ARB to
                               TEXTURE_COMPRESSED_IMAGE_SIZE_ARB.
                             * Querying image size on uncompressed images is
                               now an INVALID_OPERATION error.
                             * INVALID_VALUE error is generated if <imageSize>
                               is inconsistent with the image data.  This
                               restriction may be overridden by specific
                               extensions only if requiring an image size
                               check is unreasonable.
                             * Added documentaion of undefined behavior for
                               CompressedTexImage/SubImage if the image data
                               is encoded in a manner inconsistent with the
                               spec defining the compressed image format.
                             * Fixed issue (16).  Text was truncated.
                             * Modified invariance section.  <data> can not
                               affect the choice of compressed internal
                               format, but can theoretically affect regular
                               component resolution.
                             * Add new function GetCompressedTexImage to deal
                               with subtle GLX issues.
                             * GLX protocol for CompressedTexImage/SubImage
                               and GetCompressedTexImage holds both a padded
                               image size (for GLX data transfer) and actual
                               image size (for packing in user buffers).

                             Minor wording clean-ups.

                             Added enum and GLX opcode values allocated from
                             OpenGL Extensions and GLX registries.

    0.81, 03/07/00 prbrown1: Fixed error documentation for TexSubImage calls
                             of arbitrary alignment (did not document that the
                             internal format had to be compressed).  Removed
                             references to CopyTexImage3D, which doesn't
                             actually exist.

                             Per Kurt Akeley suggestions: (1) Renamed
                             TexImageCompressed to CompressedTexImage to
                             conform with naming conventions, (2) clarified
                             that the main feature distinguishing
                             CompressedTex[Sub]Image calls from normal
                             Tex[Sub]Image calls is compressed input data, (3)
                             added query to explicitly determine whether the
                             internal format of a texture is compressed.

    0.8,  02/23/00 prbrown1: Marked previously unresolved issues as resolved
                             per the ARB working group.  Added docs for errors
                             not specific to compression for the new
                             CompressedTexImage and CompressedTexSubImage
                             calls.  Added queries to enumerate specific
```

```
                                 compressed texture formats.
    0.76, 02/16/00 prbrown1: Removed "gl" and "GL_" prefixes.
    0.75, 02/07/00 prbrown1: Incorporated feedback from 12/99 ARB meeting
                             and a number of other revisions.
    0.7,  12/03/99 prbrown1: Incorporated comments from public review of 0.2
                             document.
    0.2,  10/28/99 prbrown1: Renamed to ARB_texture_compression.  Significant
                             functional changes.
    0.11, 10/21/99 prbrown1: Edits suggested by 3dfx.
    0.1,  10/19/99 prbrown1: Initial revision.
```

Name

    ARB_texture_cube_map

Name Strings

    GL_ARB_texture_cube_map

Notice

Status

    Complete. Approved by ARB on 12/8/1999

Version

    Last Modified Date: December 14, 1999

Number

    ARB Extension #7

Dependencies

    None.

    Written based on the wording of the OpenGL 1.2.1 specification but
    not dependent on it.

Overview

This extension provides a new texture generation scheme for cube map textures. Instead of the current texture providing a 1D, 2D, or 3D lookup into a 1D, 2D, or 3D texture image, the texture is a set of six 2D images representing the faces of a cube. The (s,t,r) texture coordinates are treated as a direction vector emanating from the center of a cube. At texture generation time, the interpolated per-fragment (s,t,r) selects one cube face 2D image based on the largest magnitude coordinate (the major axis). A new 2D (s,t) is calculated by dividing the two other coordinates (the minor axes values) by the major axis value. Then the new (s,t) is used to lookup into the selected 2D texture image face of the cube map.

Unlike a standard 1D, 2D, or 3D texture that have just one target, a cube map texture has six targets, one for each of its six 2D texture image cube faces. All these targets must be consistent, complete, and have equal width and height (ie, square dimensions).

This extension also provides two new texture coordinate generation modes for use in conjunction with cube map texturing. The reflection map mode generates texture coordinates (s,t,r) matching the vertex's eye-space reflection vector. The reflection map mode is useful for environment mapping without the singularity inherent in sphere mapping. The normal map mode generates texture coordinates (s,t,r) matching the vertex's transformed eye-space normal. The normal map mode is useful for sophisticated cube map texturing-based diffuse lighting models.

The intent of the new texgen functionality is that an application using cube map texturing can use the new texgen modes to automatically generate the reflection or normal vectors used to look up into the cube map texture.

An application note: When using cube mapping with dynamic cube maps (meaning the cube map texture is re-rendered every frame), by keeping the cube map's orientation pointing at the eye position, the texgen-computed reflection or normal vector texture coordinates can be always properly oriented for the cube map. However if the cube map is static (meaning that when view changes, the cube map texture is not updated), the texture matrix must be used to rotate the texgen-computed reflection or normal vector texture coordinates to match the orientation of the cube map. The rotation can be computed based on two vectors: 1) the direction vector from the cube map center to the eye position (both in world coordinates), and 2) the cube map orientation in world coordinates. The axis of rotation is the cross product of these two vectors; the angle of rotation is the arcsin of the dot product of these two vectors.

Issues

Should we place the normal/reflection vector in the (s,t,r) texture coordinates or (s,t,q) coordinates?

RESOLUTION: (s,t,r). Even if hardware uses "q" for the third component, the API should claim to support generation of (s,t,r) and let the texture matrix (through a concatenation with the user-supplied texture matrix) move "r" into "q".

Should the texture coordinate generation functionality for cube mapping be specified as a distinct extension from the actual cube map texturing functionality?

RESOLUTION: NO. Real applications and real implementations of cube mapping will tie the texgen and texture generation functionality together. Applications won't have to query two separate extensions then.

While applications will almost always want to use the texgen functionality for automatically generating the reflection or normal vector as texture coordinates (s,t,r), this extension does permit an application to manually supply the reflection or normal vector through glTexCoord3f explicitly.

Note that the NV_texgen_reflection extension does "unbundle" the texgen functionality from cube maps.

Should you be able to have some texture coordinates computing REFLECTION_MAP_ARB and others not? Same question with NORMAL_MAP_ARB.

RESOLUTION: YES. This is the way that SPHERE_MAP works. It is not clear that this would ever be useful though.

Should something special be said about the handling of the q texture coordinate for this spec?

RESOLUTION: NO. But the following paragraph is useful for implementors concerned about the handling of q.

The REFLECTION_MAP_ARB and NORMAL_MAP_ARB modes are intended to supply reflection and normal vectors for cube map texturing hardware. When these modes are used for cube map texturing, the generated texture coordinates can be thought of as an reflection vector. The value of the q texture coordinate then simply scales the vector but does not change its direction. Because only the vector direction (not the vector magnitude) matters for cube map texturing, implementations are free to leave q undefined when any of the s, t, or r texture coordinates are generated using REFLECTION_MAP_ARB or NORMAL_MAP_ARB.

How should the cube faces be labeled?

RESOLUTION: Match the render man specification's names of "px" (positive X), "nx" (negative x), "py", "ny", "pz", and "nz". There does not actually need to be an "ordering for the faces" (Direct3D 7.0 does number their cube map faces.) For this extension, the symbolic target names (TEXTURE_CUBE_MAP_POSITIVE_X_ARB, etc) is sufficient without requiring any specific ordering.

What coordinate system convention should be used? LHS or RHS?

RESOLUTION: The coordinate system is left-handed if you think of yourself within the cube. The coordinate system is right-handed if you think of yourself outside the cube.

This matches the convention of the RenderMan interface. If you look at Figure 12.8 (page 265) in "The RenderMan Companion", think of the cube being folded up with the observer inside the cube. Then the coordinate system convention is left-handed.

The spec just linearly interpolates the reflection vectors computed per-vertex across polygons. Is there a problem interpolating reflection vectors in this way?

Probably. The better approach would be to interpolate the eye vector and normal vector over the polygon and perform the reflection vector computation on a per-fragment basis. Not doing so is likely to lead to artifacts because angular changes in the normal vector result in twice as large a change in the reflection vector as normal vector changes. The effect is likely to be reflections that become glancing reflections too fast over the surface of the polygon.

Note that this is an issue for REFLECTION_MAP_ARB, but not NORMAL_MAP_ARB.

What happens if an (s,t,q) is passed to cube map generation that is close to (0,0,0), ie. a degenerate direction vector?

RESOLUTION: Leave undefined what happens in this case (but may not lead to GL interruption or termination).

Note that a vector close to (0,0,0) may be generated as a result of the per-fragment interpolation of (s,t,r) between vertices.

Do we need a distinct proxy texture mechanism for cube map textures?

RESOLUTION: YES. Cube map textures take up six times the memory as a conventional 2D image texture so proxy 2D texture determinations won't be of value for a cube map texture. Cube maps need their own proxy target.

Should we require the 2D texture image width and height to be identical (ie, square only)?

RESOLUTION: YES. This limitation is quite a reasonable limitation and DirectX 7 has the same limitation.

This restriction is enforced by generating an INVALID_VALUE when calling TexImage2D or CopyTexImage2D with a non-equal width and height.

Some consideration was given to enforcing the "squarness" constraint as a texture consistency constraint. This is confusing however since the squareness is known up-front at texture image specification time so it seems confusing to silently report the usage error as a texture consistency issue.

Texture consistency still says that all the level 0 textures of all six faces must have the same square size.

If some combination of 1D, 2D, 3D, and cube map texturing is enabled, which really operates?

RESOLUTION: Cube map texturing. In OpenGL 1.2, 3D takes priority over 2D takes priority over 1D. Cube mapping should take priority over all conventional n-dimensional texturing schemes.

Does anything need to be said about combining cube mapping with multitexture?

RESOLUTION: NO. Cube mapping should be available on all texture units. The hardware should fully orthogonal in its handling of cube map textures.

Does it make sense to support borders for cube map textures.

Actually, it does. It would be nice if the texture border pixels match the appropriate texels from the edges of the other cube map faces that they junction with. For this reason, we'll leave the texture border capability implicitly supported.

How does mipmap level-of-detail selection work for cube map textures?

The existing spec's language about LOD selection is fine.

Should the implementation dependent value for the maximum texture size for a cube map be the same as MAX_TEXTURE_SIZE?

RESOLUTION: NO. OpenGL 1.2 has a different MAX_3D_TEXTURE_SIZE for 3D textures, and cube maps should take six times more space than a 2D texture map of the same width & height. The implementation dependent MAX_CUBE_MAP_TEXTURE_SIZE_ARB constant should be used for cube maps then.

Note that the proxy cube map texture provides a better way to find out the maximum cube map texture size supported since the proxy mechanism can take into account the internal format, etc.

In section 3.8.10 when the "largest magnitude coordinate direction" is choosen, what happens if two or more of the coordinates (rx,ry,rz) have the identical magnitude?

RESOLUTION: Implementations can define their own rule to choose the largest magnitude coordinate direction whne two or more of the coordinates have the identical magnitude. The only restriction is that the rule must be deterministic and depend only on (rx,ry,rz).

In practice, (s,t,r) is interpolated across polygons so the cases where |s|==|t|, etc. are pretty arbitary (the equality depends on interpolation precision). This extension could mandate a particular rule, but that seems heavy-handed and there is no good reason that multiple vendors should be forced to implement the same rule.

Should there be limits on the supported border modes for cube maps?

RESOLUTION: NO. The specificiation is written so that cube map texturing proceeds just like conventional 2D texture mapping once the face determination is made.

Therefore, all OpenGL texture wrap modes should be supported though some modes are clearly inappropriate for cube maps. The WRAP mode is almost certainly incorrect for cube maps. Likewise, the CLAMP mode without a texture border is almost certainly incorrect for cube maps. CLAMP when a texture border is present and CLAMP_TO_EDGE are both reasonably suited for cube maps. Ideally, CLAMP with a texture border works best if the cube map edges can be replicated in the approriate texture borders of adjacent cube map faces. In practice, CLAMP_TO_EDGE works reasonably well in most circumstances.

Perhaps another extension could support a special cube map wrap mode that automatically wraps individual texel fetches to the appropriate adjacent cube map face. The benefit from such a mode is small and the implementation complexity is involved so this wrap mode should not be required for a basic cube map texture extension.

How is mipmap LOD selection handled for cube map textures?

RESOLUTION: The specification is written so that cube map texturing proceeds just like conventional 2D texture mapping once the face determination is made.

Thereforce, the partial differentials in Section 3.8.5 (page 126) should be evaluated for the u and v parameters based on the post-face determination s and t.

In Section 2.10.3 "Normal Transformation", there are several versions of the eye-space normal vector to choose from. Which one should the NORMAL_MAP_ARB texgen mode use?

RESOLUTION: nf. The nf vector is the final normal, post-rescale normal and post-normalize. In practice, the rescale normal and normalize operations do not change the direction of the vector so the choice of which version of transformed normal is used is not important for cube maps.

New Procedures and Functions

None

New Tokens

Accepted by the <param> parameters of TexGend, TexGenf, and TexGeni when <pname> parameter is TEXTURE_GEN_MODE:

```
NORMAL_MAP_ARB                     0x8511
REFLECTION_MAP_ARB                 0x8512
```

When the <pname> parameter of TexGendv, TexGenfv, and TexGeniv is TEXTURE_GEN_MODE, then the array <params> may also contain NORMAL_MAP_ARB or REFLECTION_MAP_ARB.

Accepted by the <cap> parameter of Enable, Disable, IsEnabled, and by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev, and by the <target> parameter of BindTexture, GetTexParameterfv, GetTexParameteriv, TexParameterf, TexParameteri, TexParameterfv, and TexParameteriv:

```
TEXTURE_CUBE_MAP_ARB               0x8513
```

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
TEXTURE_BINDING_CUBE_MAP_ARB       0x8514
```

```
    Accepted by the <target> parameter of GetTexImage,
    GetTexLevelParameteriv, GetTexLevelParameterfv, TexImage2D,
    CopyTexImage2D, TexSubImage2D, and CopySubTexImage2D:

        TEXTURE_CUBE_MAP_POSITIVE_X_ARB     0x8515
        TEXTURE_CUBE_MAP_NEGATIVE_X_ARB     0x8516
        TEXTURE_CUBE_MAP_POSITIVE_Y_ARB     0x8517
        TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB     0x8518
        TEXTURE_CUBE_MAP_POSITIVE_Z_ARB     0x8519
        TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB     0x851A

    Accepted by the <target> parameter of GetTexLevelParameteriv,
    GetTexLevelParameterfv, GetTexParameteriv, and TexImage2D:

        PROXY_TEXTURE_CUBE_MAP_ARB          0x851B

    Accepted by the <pname> parameter of GetBooleanv, GetDoublev,
    GetIntegerv, and GetFloatv:

        MAX_CUBE_MAP_TEXTURE_SIZE_ARB       0x851C
```

Additions to Chapter 2 of the 1.2 Specification (OpenGL Operation)

-- Section 2.10.4 "Generating Texture Coordinates"

```
      Change the last sentence in the 1st paragraph (page 37) to:

      "If <pname> is TEXTURE_GEN_MODE, then either <params> points to
      or <param> is an integer that is one of the symbolic constants
      OBJECT_LINEAR, EYE_LINEAR, SPHERE_MAP, REFLECTION_MAP_ARB, or
      NORMAL_MAP_ARB."

      Add these paragraphs after the 4th paragraph (page 38):

      "If TEXTURE_GEN_MODE indicates REFLECTION_MAP_ARB, compute the
      reflection vector r as described for the SPHERE_MAP mode.  Then the
      value assigned to an s coordinate (the first TexGen argument value
      is S) is s = rx; the value assigned to a t coordinate is t = ry;
      and the value assigned to a r coordinate is r = rz.  Calling TexGen
      with a <coord> of Q when <pname> indicates REFLECTION_MAP_ARB
      generates the error INVALID_ENUM.

      If TEXTURE_GEN_MODE indicates NORMAL_MAP_ARB, compute the normal
      vector nf as described in section 2.10.3.  Then the value assigned
      to an s coordinate (the first TexGen argument value is S) is s =
      nfx; the value assigned to a t coordinate is t = nfy; and the
      value assigned to a r coordinate is r = nfz.  (The values nfx, nfy,
      and nfz are the components of nf.)  Calling TexGen with a <coord>
      of Q when <pname> indicates NORMAL_MAP_ARB generates the error
      INVALID_ENUM.

      The last paragraph's first sentence (page 38) should be changed to:

      "The state required for texture coordinate generation comprises a
      five-valued integer for each coordinate indicating coordinate
      generation mode, ..."
```

Additions to Chapter 3 of the 1.2 Specification (Rasterization)

-- Section 3.6.5 "Pixel Transfer Operations" under "Convolution"

Change this paragraph (page 103) to say:

... "If CONVOLUTION_2D is enabled, the two-dimensional convolution filter is applied only to the two-dimensional images passed to DrawPixels, CopyPixels, ReadPixels, TexImage2D, TexSubImage2D, CopyTexImage2D, CopyTexSubImage2D, and CopyTexSubImage3D, and returned by GetTexImage with one of the targets TEXTURE_2D, TEXTURE_CUBE_MAP_POSITIVE_X_ARB, TEXTURE_CUBE_MAP_NEGATIVE_X_ARB, TEXTURE_CUBE_MAP_POSITIVE_Y_ARB, TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB, TEXTURE_CUBE_MAP_POSITIVE_Z_ARB, or TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB."

-- Section 3.8.1 "Texture Image Specification"

Change the second and third to last sentences on page 116 to:

"<target> must be one of TEXTURE_2D for a 2D texture, or one of TEXTURE_CUBE_MAP_POSITIVE_X_ARB, TEXTURE_CUBE_MAP_NEGATIVE_X_ARB, TEXTURE_CUBE_MAP_POSITIVE_Y_ARB, TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB, TEXTURE_CUBE_MAP_POSITIVE_Z_ARB, or TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB for a cube map texture. Additionally, <target> can be either PROXY_TEXTURE_2D for a 2D proxy texture or PROXY_TEXTURE_CUBE_MAP_ARB for a cube map proxy texture as discussed in section 3.8.7."

Add the following paragraphs after the first paragraph on page 117:

"A 2D texture consists of a single 2D texture image. A cube map texture is a set of six 2D texture images. The six cube map texture targets form a single cube map texture though each target names a distinct face of the cube map. The TEXTURE_CUBE_MAP_*_ARB targets listed above update their appropriate cube map face 2D texture image. Note that the six cube map 2D image tokens such as TEXTURE_CUBE_MAP_POSITIVE_X_ARB are used when specifying, updating, or querying one of a cube map's six 2D image, but when enabling cube map texturing or binding to a cube map texture object (that is when the cube map is accessed as a whole as opposed to a particular 2D image), the TEXTURE_CUBE_MAP_ARB target is specified.

When the target parameter to TexImage2D is one of the six cube map 2D image targets, the error INVALID_VALUE is generated if the width and height parameters are not equal.

If cube map texturing is enabled at the time a primitive is rasterized and if the set of six targets are not "cube complete", then it is as if texture mapping were disabled. The targets of a cube map texture are "cube complete" if the array 0 of all six targets have identical, positive, and square dimensions, the array 0 of all six targets were specified with the same internalformat, and the array 0 of all six targets have the same border width."

After the 14th paragraph (page 116) add:

"In a similiar fashion, the maximum allowable width and height (they must be the same) of a cube map texture must be at least

2^(k-lod)+2bt for image arrays level 0 through k, where k is the
log base 2 of MAX_CUBE_MAP_TEXTURE_SIZE_ARB."

-- Section 3.8.2 "Alternate Texture Image Specification Commands"

Update the second paragraph (page 120) to say:

... "Currently, <target> must be
TEXTURE_2D, TEXTURE_CUBE_MAP_POSITIVE_X_ARB,
TEXTURE_CUBE_MAP_NEGATIVE_X_ARB, TEXTURE_CUBE_MAP_POSITIVE_Y_ARB,
TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB, TEXTURE_CUBE_MAP_POSITIVE_Z_ARB,
or TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB." ...

Add after the second paragraph (page 120), the following:

"When the target parameter to CopyTexImage2D is one of the six cube
map 2D image targets, the error INVALID_VALUE is generated if the
width and height parameters are not equal."

Update the fourth paragraph (page 121) to say:

... "Currently the target arguments of TexSubImage1D and
CopyTexSubImage1D must be TEXTURE_1D, the <target> arguments of
TexSubImage2D and CopyTexSubImage2D must be one of TEXTURE_2D,
TEXTURE_CUBE_MAP_POSITIVE_X_ARB, TEXTURE_CUBE_MAP_NEGATIVE_X_ARB,
TEXTURE_CUBE_MAP_POSITIVE_Y_ARB, TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB,
TEXTURE_CUBE_MAP_POSITIVE_Z_ARB, or TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB,
and the <target> arguments of TexSubImage3D and CopyTexSubImage3D
must be TEXTURE_3D." ...

-- Section 3.8.3 "Texture Parameters"

Change paragraph one (page 124) to say:

... "<target> is the target, either TEXTURE_1D,
TEXTURE_2D, TEXTURE_3D, or TEXTURE_CUBE_MAP_ARB." ...

Add a final paragraph saying:

"Texture parameters for a cube map texture apply to cube map
as a whole; the six distinct 2D texture images use the
texture parameters of the cube map itself.

-- Section 3.8.5 "Texture Minification" under "Mipmapping"

Change the first full paragraph on page 130 to:

... "If texturing is enabled for one-, two-, or three-dimensional
texturing but not cube map texturing (and TEXTURE_MIN_FILTER
is one that requires a mipmap) at the time a primitive is
rasterized and if the set of arrays TEXTURE_BASE_LEVEL through q =
min{p,TEXTURE_MAX_LEVEL} is incomplete, based on the dimensions of
array 0, then it is as if texture mapping were disabled."

```
    Follow the first full paragraph on page 130 with:

    "If cube map texturing is enabled and TEXTURE_MIN_FILTER is one that
    requires mipmap levels at the time a primitive is rasterized and
    if the set of six targets are not "mipmap cube complete", then it
    is as if texture mapping were disabled.  The targets of a cube map
    texture are "mipmap cube complete" if the six cube map targets are
    "cube complete" and the set of arrays TEXTURE_BASE_LEVEL through
    q are not incomplete (as described above)."
```

-- Section 3.8.7 "Texture State and Proxy State"

```
    Change the first sentence of the first paragraph (page 131) to say:

    "The state necessary for texture can be divided into two categories.
    First, there are the nine sets of mipmap arrays (one each for the
    one-, two-, and three-dimensional texture targets and six for the
    cube map texture targets) and their number." ...

    Change the second paragraph (page 132) to say:

    "In addition to the one-, two-, three-dimensional, and the six cube
    map sets of image arrays, the partially instantiated one-, two-,
    and three-dimensional and one cube map sets of proxy image arrays
    are maintained." ...

    After the third paragraph (page 132) add:

    "The cube map proxy arrays are operated on in the same manner
    when TexImage2D is executed with the <target> field specified as
    PROXY_TEXTURE_CUBE_MAP_ARB with the addition that determining that a
    given cube map texture is supported with PROXY_TEXTURE_CUBE_MAP_ARB
    indicates that all six of the cube map 2D images are supported.
    Likewise, if the specified PROXY_TEXTURE_CUBE_MAP_ARB is not
    supported, none of the six cube map 2D images are supported."

    Change the second sentence of the fourth paragraph (page 132) to:

    "Therefore PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_3D,
    and PROXY_TEXTURE_CUBE_MAP_ARB cannot be used as textures, and their
    images must never be queried using GetTexImage." ...
```

-- Section 3.8.8 "Texture Objects"

```
    Change the first sentence of the first paragraph (page 132) to say:

    "In addition to the default textures TEXTURE_1D, TEXTURE_2D,
    TEXTURE_3D, and TEXTURE_CUBE_MAP_ARB, named one-, two-,
    and three-dimensional texture objects and cube map texture objects
    can be created and operated on." ...

    Change the second paragraph (page 132) to say:

    "A texture object is created by binding an unused name to
    TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, or TEXTURE_CUBE_MAP_ARB." ...
    "If the new texture object is bound to TEXTURE_1D, TEXTURE_2D,
```

TEXTURE_3D, or TEXTURE_CUBE_MAP_ARB, it remains a one-, two-, three-dimensional, or cube map texture until it is deleted."

Change the third paragraph (page 133) to say:

"BindTexture may also be used to bind an existing texture object to either TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, or TEXTURE_CUBE_MAP_ARB."

Change paragraph five (page 133) to say:

"In the initial state, TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, and TEXTURE_CUBE_MAP have one-dimensional, two-dimensional, three-dimensional, and cube map state vectors associated with them respectively." ... "The initial, one-dimensional, two-dimensional, three-dimensional, and cube map texture is therefore operated upon, queried, and applied as TEXTURE_1D, TEXTUER_2D, TEXTURE_3D, and TEXTURE_CUBE_MAP_ARB respectively while 0 is bound to the corresponding targets."

Change paragraph six (page 133) to say:

... "If a texture that is currently bound to one of the targets TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, or TEXTURE_CUBE_MAP_ARB is deleted, it is as though BindTexture has been executed with the same <target> and <texture> zero." ...

-- Section 3.8.10 "Texture Application"

Replace the beginning sentences of the first paragraph (page 138) with:

"Texturing is enabled or disabled using the generic Enable and Disable commands, respectively, with the symbolic constants TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, or TEXTURE_CUBE_MAP_ARB to enable the one-dimensional, two-dimensional, three-dimensional, or cube map texturing respectively. If both two- and one-dimensional textures are enabled, the two-dimensional texture is used. If the three-dimensional and either of the two- or one-dimensional textures is enabled, the three-dimensional texture is used. If the cube map texture and any of the three-, two-, or one-dimensional textures is enabled, then cube map texturing is used. If texturing is disabled, a rasterized fragment is passed on unaltered to the next stage of the GL (although its texture coordinates may be discarded). Otherwise, a texture value is found according to the parameter values of the currently bound texture image of the appropriate dimensionality.

However, when cube map texturing is enabled, the rules are more complicated. For cube map texturing, the (s,t,r) texture coordinates are treated as a direction vector (rx,ry,rz) emanating from the center of a cube. (The q coordinate can be ignored since it merely scales the vector without affecting the direction.) At texture application time, the interpolated per-fragment (s,t,r) selects one of the cube map face's 2D image based on the largest magnitude coordinate direction (the major axis direction). If two or more coordinates have the identical magnitude, the implementation may define the rule to disambiguate this situation. The rule must be deterministic and depend only on (rx,ry,rz). The target column in the table below explains how the major axis direction maps to the 2D image of a particular cube map target.

major axis direction	target	sc	tc	ma
+rx	TEXTURE_CUBE_MAP_POSITIVE_X_ARB	-rz	-ry	rx
-rx	TEXTURE_CUBE_MAP_NEGATIVE_X_ARB	+rz	-ry	rx
+ry	TEXTURE_CUBE_MAP_POSITIVE_Y_ARB	+rx	+rz	ry
-ry	TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB	+rx	-rz	ry
+rz	TEXTURE_CUBE_MAP_POSITIVE_Z_ARB	+rx	-ry	rz
-rz	TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB	-rx	-ry	rz

Using the sc, tc, and ma determined by the major axis direction as specified in the table above, an updated (s,t) is calculated as follows

```
   s   =   ( sc/|ma| + 1 ) / 2
   t   =   ( tc/|ma| + 1 ) / 2
```

This new (s,t) is used to find a texture value in the determined face's 2D texture image using the rules given in sections 3.8.5 and 3.8.6." ...

Additions to Chapter 4 of the 1.2 Specification (Per-Fragment Operations and the Frame Buffer)

None

Additions to Chapter 5 of the 1.2 Specification (Special Functions)

-- Section 5.4 "Display Lists"

In the first paragraph (page 179), add PROXY_TEXTURE_CUBE_MAP_ARB to the list of PROXY_* tokens.

Additions to Chapter 6 of the 1.2 Specification (State and State Requests)

-- Section 6.1.3 "Enumerated Queries"

Change the fourth paragraph (page 183) to say:

"The GetTexParameter parameter <target> may be one of TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, or TEXTURE_CUBE_MAP_ARB, indicating the currently bound one-dimensional, two-dimensional, three-dimensional, or cube map texture object. For GetTexLevelParameter, <target> may be one of TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, TEXTURE_CUBE_MAP_POSITIVE_X_ARB, TEXTURE_CUBE_MAP_NEGATIVE_X_ARB, TEXTURE_CUBE_MAP_POSITIVE_Y_ARB, TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB, TEXTURE_CUBE_MAP_POSITIVE_Z_ARB, TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB, PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_3D, or PROXY_TEXTURE_CUBE_MAP_ARB, indicating the one-dimensional texture object, two-dimensional texture object, three-dimensional texture object, or one of the six distinct 2D images making up the cube map texture object or one-dimensional, two-dimensional, three-dimensional, or cube map proxy state vector. Note that TEXTURE_CUBE_MAP_ARB is not a valid <target> parameter for

    GetTexLevelParameter because it does not specify a particular cube
    map face."

-- Section 6.1.4 "Texture Queries"

    Change the first paragraph (page 184) to read:

    ... "It is somewhat different from the other get commands; <tex>
    is a symbolic value indicating which texture (or texture face in the
    case of a cube map texture target name) is to be obtained.
    TEXTURE_1D indicates a one-dimensional texture, TEXTURE_2D
    indicates a two-dimensional texture, TEXTURE_3D indicates a
    three-dimensional texture, and TEXTURE_CUBE_MAP_POSITIVE_X_ARB,
    TEXTURE_CUBE_MAP_NEGATIVE_X_ARB, TEXTURE_CUBE_MAP_POSITIVE_Y_ARB,
    TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB, TEXTURE_CUBE_MAP_POSITIVE_Z_ARB,
    and TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB indicate the respective face of
    a cube map texture.

Additions to the GLX Specification

    None

Errors

    INVALID_ENUM is generated when TexGen is called with a <coord> of Q
    when <pname> indicates REFLECTION_MAP_ARB or NORMAL_MAP_ARB.

    INVALID_VALUE is generated when the target parameter to TexImage2D
    or CopyTexImage2D is one of the six cube map 2D image targets and
    the width and height parameters are not equal.

New State

(table 6.12, p202) add the following entries:

Get Value	Type	Get Command	Initial Value	Description	Sec	Attribute
TEXTURE_CUBE_MAP_ARB	B	IsEnabled	False	True if cube map texturing is enabled	3.8.10	texture/enable
TEXTURE_BINDING_CUBE_MAP_ARB	Z+	GetIntegerv	0	Texture object for TEXTURE_CUBE_MAP	3.8.8	texture
TEXTURE_CUBE_MAP_POSITIVE_X_ARB	nxI	GetTexImage	see 3.8	positive x face cube map texture image at lod i	3.8	-
TEXTURE_CUBE_MAP_NEGATIVE_X_ARB	nxI	GetTexImage	see 3.8	negative x face cube map texture image at lod i	3.8	-
TEXTURE_CUBE_MAP_POSITIVE_Y_ARB	nxI	GetTexImage	see 3.8	positive y face cube map texture image at lod i	3.8	-
TEXTURE_CUBE_MAP_NEGATIVE_Y_ARB	nxI	GetTexImage	see 3.8	negative y face cube map texture image at lod i	3.8	-
TEXTURE_CUBE_MAP_POSITIVE_Z_ARB	nxI	GetTexImage	see 3.8	positive z face cube map texture image at lod i	3.8	-
TEXTURE_CUBE_MAP_NEGATIVE_Z_ARB	nxI	GetTexImage	see 3.8	negative z face cube map texture image at lod i	3.8	-

(table 6.14, p204) change the entry for TEXTURE_GEN_MODE to:

Get Value	Type	Get Command	Initial Value	Description	Sec	Attribute
TEXTURE_GEN_MODE	4xZ5	GetTexGeniv	EYE_LINEAR	Function used for texgen (for s,t,r, and q)	2.10.4	texture

(the type changes from 4xZ3 to 4xZ5)

New Implementation Dependent State

(table 6.24, p214) add the following entry:

Get Value	Type	Get Command	Minimum Value	Description	Sec	Attribute
MAX_CUBE_MAP_TEXTURE_SIZE_ARB	Z+	GetIntegerv	16	Maximum cube map texture image dimension	3.8.1	-

Backwards Compatibility

This extension replaces EXT_texture_cube_map. The tokens and name strings now refer to ARB instead of EXT. Enumerant values are unchanged.

ARB Extension #17

Dependencies

This extension is written against the OpenGL 1.2.1 Specification.
OpenGL 1.1 and ARB_multitexture are required for this extension.

Overview

New texture environment function COMBINE_ARB allows programmable
texture combiner operations, including:

```
    REPLACE                 Arg0
    MODULATE                Arg0 * Arg1
    ADD                     Arg0 + Arg1
    ADD_SIGNED_ARB          Arg0 + Arg1 - 0.5
    SUBTRACT_ARB            Arg0 - Arg1
    INTERPOLATE_ARB         Arg0 * (Arg2) + Arg1 * (1-Arg2)
```

where Arg0, Arg1 and Arg2 are derived from

```
    PRIMARY_COLOR_ARB       primary color of incoming fragment
    TEXTURE                 texture color of corresponding texture unit
    CONSTANT_ARB            texture environment constant color
    PREVIOUS_ARB            result of previous texture environment; on
                            texture unit 0, this maps to PRIMARY_COLOR_ARB
```

In addition, the result may be scaled by 1.0, 2.0 or 4.0.

Issues

1. Should the explicit bias be removed in favor of an implcit bias as
   part of a ADD_SIGNED_ARB function?

   - RESOLVED: Yes. This pre-scale bias is a special case and will
     be treated as such.

2. Should the primary color of the incoming fragment be available to
   all texture environments? Currently it is only available to the
   texture environment of texture unit 0.

   - RESOLVED: Yes. PRIMARY_COLOR_ARB has been added as an input
     source.

3. Should textures from other texture units be allowed as sources?

   - RESOLVED: NO. Even though this adds a lot of flexibility that folks can use today, there is not enough support amonst the ARB participants to add it to the base spec.

4. All of the 1.2 modes except BLEND can be expressed in terms of this extension. Should texture color be allowed as a source for Arg2, so all of the 1.2 modes can be expressed? If so, should all color sources be allowed, to maintain orthogonality?

   - RESOLVED: Yes. This seems to be a reasonable area to expand functionality and remain backwards compatible with the EXT version of the extension.

5. If the texture environment for a given texture unit does not reference the texture object that is bound to that texture unit, does a valid texture object need to be bound that unit?

   - RESOLVED: Yes. Each texture unit implicitly references the texture object that is bound to that unit, regardless of the texture environment function. This may require that applications bind a dummy texture to the texture unit.

6. Should we allow the secondary color to take part in texture blending?

   - RESOLVED: Not in this extension. Secondary color was defined as a specular part of the lit color and does not have associated alpha. In order to do this right, the secondary color extension needs to be fixed first to allow a full featured color and clearly state the interaction of how it interacts with the color sum stage.

7. How exactly is this ARB extension different from the EXT version?

   - RESOLVED:

     1) This extension adds the GL_SUBTRACT_ARB mode

     2) OPERAND2_RGB_ARB can use SRC_COLOR, ONE_MINUS_SRC_COLOR, SRC_ALPHA, and ONE_MINUS_SRC_ALPHA instead of just SRC_ALPHA (NV_texture_env_combine4 already provides this).

     3) OPERAND2_ALPHA_ARB can use SRC_ALPHA and ONE_MINUS_SRC_ALPHA instead of just SRC_ALPHA (NV_texture_env_combine4 already provides this).

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

None

Additions to Chapter 3 of the GL Specification (Rasterization)

Added to subsection 3.8.9, before the paragraph describing the state requirements:

If the value of TEXTURE_ENV_MODE is COMBINE_ARB, the form of the texture function depends on the values of COMBINE_RGB_ARB and COMBINE_ALPHA_ARB, according to table 3.20. The RGB and ALPHA results of the texture function are then multiplied by the values of RGB_SCALE_ARB and ALPHA_SCALE, respectively. The results are clamped to [0,1].

COMBINE_RGB_ARB	Texture Function
REPLACE	Arg0
MODULATE	Arg0 * Arg1
ADD	Arg0 + Arg1
ADD_SIGNED_ARB	Arg0 + Arg1 - 0.5
INTERPOLATE_ARB	Arg0 * (Arg2) + Arg1 * (1-Arg2)
SUBTRACT_ARB	Arg0 - Arg1

COMBINE_ALPHA_ARB	Texture Function
REPLACE	Arg0
MODULATE	Arg0 * Arg1
ADD	Arg0 + Arg1
ADD_SIGNED_ARB	Arg0 + Arg1 - 0.5
INTERPOLATE_ARB	Arg0 * (Arg2) + Arg1 * (1-Arg2)
SUBTRACT_ARB	Arg0 - Arg1

Table 3.20: COMBINE_ARB texture functions

The arguments Arg0, Arg1 and Arg2 are determined by the values of SOURCE<n>_RGB_ARB, SOURCE<n>_ALPHA_ARB, OPERAND<n>_RGB_ARB and OPERAND<n>_ALPHA_ARB. In the following two tables, Ct and At are the filtered texture RGB and alpha values; Cc and Ac are the texture environment RGB and alpha values; Cf and Af are the RGB and alpha of the primary color of the incoming fragment; and Cp and Ap are the RGB and alpha values resulting from the previous texture environment. On texture environment 0, Cp and Ap are identical to Cf and Af, respectively. The relationship is described in tables 3.21 and 3.22.

SOURCE<n>_RGB_ARB	OPERAND<n>_RGB_ARB	Argument
TEXTURE	SRC_COLOR	Ct
	ONE_MINUS_SRC_COLOR	(1-Ct)
	SRC_ALPHA	At
	ONE_MINUS_SRC_ALPHA	(1-At)
CONSTANT_ARB	SRC_COLOR	Cc
	ONE_MINUS_SRC_COLOR	(1-Cc)
	SRC_ALPHA	Ac
	ONE_MINUS_SRC_ALPHA	(1-Ac)
PRIMARY_COLOR_ARB	SRC_COLOR	Cf
	ONE_MINUS_SRC_COLOR	(1-Cf)
	SRC_ALPHA	Af
	ONE_MINUS_SRC_ALPHA	(1-Af)
PREVIOUS_ARB	SRC_COLOR	Cp
	ONE_MINUS_SRC_COLOR	(1-Cp)
	SRC_ALPHA	Ap
	ONE_MINUS_SRC_ALPHA	(1-Ap)

Table 3.21: Arguments for COMBINE_RGB_ARB functions

SOURCE<n>_ALPHA_ARB	OPERAND<n>_ALPHA_ARB	Argument
TEXTURE	SRC_ALPHA	At
	ONE_MINUS_SRC_ALPHA	(1-At)
CONSTANT_ARB	SRC_ALPHA	Ac
	ONE_MINUS_SRC_ALPHA	(1-Ac)
PRIMARY_COLOR_ARB	SRC_ALPHA	Af
	ONE_MINUS_SRC_ALPHA	(1-Af)
PREVIOUS_ARB	SRC_ALPHA	Ap
	ONE_MINUS_SRC_ALPHA	(1-Ap)

Table 3.22: Arguments for COMBINE_ALPHA_ARB functions

The mapping of texture components to source components is summarized in Table 3.23. In the following table, At, Lt, It, Rt, Gt and Bt are the filtered texel values.

Base Internal Format	RGB Values	Alpha Value
ALPHA	0, 0, 0	At
LUMINANCE	Lt, Lt, Lt	1
LUMINANCE_ALPHA	Lt, Lt, Lt	At
INTENSITY	It, It, It	It
RGB	Rt, Gt, Bt	1
RGBA	Rt, Gt, Bt	At

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

None

Additions to Chapter 5 of the GL Specification (Special Functions)

None

Additions to Chapter 6 of the GL Specification (State and State Requests)

None

Additions to Appendix F of the GL Specification (ARB Extensions)

Inserted after the second paragraph of F.2.12:

If the value of TEXTURE_ENV_MODE is COMBINE_ARB, the texture function associated with a given texture unit is computed using the values specified by SOURCE<n>_RGB_ARB, SOURCE<n>_ALPHA_ARB, OPERAND<n>_RGB_ARB and OPERAND<n>_ALPHA_ARB. If TEXTURE<n>_ARB is specified as SOURCE<n>_RGB_ARB or SOURCE<n>_ALPHA_ARB, the texture value from texture unit <n> will be used in computing the texture function for this texture unit.

Inserted after the third paragraph of F.2.12:

If a texture environment for a given texture unit references a texture unit that is disabled or does not have a valid texture object bound to it, then it is as if texture is disabled for the given texture unit. Every texture unit implicitly references the texture object that is bound to it, regardless of the texture function specified by COMBINE_RGB_ARB or COMBINE_ALPHA_ARB.

Additions to the GLX Specification

Name

    ARB_texture_env_crossbar

Name Strings

    GL_ARB_texture_env_crossbar

Overview

This extension adds the capability to use the texture color from other texture units as sources to the COMBINE_ARB enviornment function. The ARB_texture_env_combine extension defined texture enviornment functions which could use the color from the current texture unit as a source. This extension adds the ability to use the color from any texture unit as a source.

NVIDIA Note

The NV_texture_env_combine4 extension provides nearly identical functionality to functionality that the ARB_texture_env_crossbar extension provides.

Unfortunately, the ARB_texture_env_crossbar's semantic for what happens when a texture environment stage references a disabled texture does not match NVIDIA's NV_texture_env_combine behavior. Due to the differing semantics and in order to maintain backward application compatibility and compatibility with the NV_texture_env_combine4 specification, NVIDIA will ***never*** advertise the ARB_texture_env_crossbar extension.

The ARB_texture_env_combine semantic is:

> Texture blending should be disabled on the texture unit that is referencing the invalid or disabled texture.

The NV_texture_env_combine4 semantic is:

> If the <n>th texture unit is disabled, the value of each component is 1.

Fortunately, this semantic is not particularly relevant for most applications because applications typically avoid sourcing a disabled, inconsistent, or invalid texture unit.

We recommend that if your application sources other texture units using the GL_COMBINE_ARB texture envionment mode, you first determine that ***either*** ARB_texture_env_crossbar ***or*** NV_texture_env_combine4 are supported. Then do not assume a particular behavior when sourcing other texture units with GL_COMBINE_ARB environment that are disabled or invalid.

OpenGL 1.4 codifies this practice by integrating the ARB_texture_env_crossbar functionality into the core OpenGL standard. The OpenGL 1.4 standard says: "If the texture environment for a given enabled texture unit references a disabled texture unit,

```
    or an invalid or incomplete texture that is bound to another unit,
    then the result of texture blending are undefined."
```

```

Name

    ARB_texture_env_dot3

Name Strings

    GL_ARB_texture_env_dot3

Status

    Complete. Approved by ARB on February 16, 2001.

Version

    Last modified date: 2001/05/16

Number

    ARB Extension #19

Dependencies

```
    This extension is written against the OpenGL 1.2.1 Specification.
    OpenGL 1.1, ARB_multitexture and ARB_texture_env_combine are required
    for this extension.
```

Overview

```
    Adds new operation to the texture combiner operations.

        DOT3_RGB_ARB                    Arg0 <dotprod> Arg1
        DOT3_RGBA_ARB                   Arg0 <dotprod> Arg1

    where Arg0, Arg1 are specified by <params> parameter of
    TexEnvf, TexEnvi, TexEnvfv, and TexEnviv when the <pname>
    parameter value is SOURCE0_RGB_ARB and SOURCE1_RGB_ARB.
```

Issues

```
 1. This extension is an ARB version of EXT_texture_env_dot3 which bears
    a copyright by ATI Technologies. Is ATI willing to have the ARB
    go ahead and modify their original spec and use it for the
    ARB extension.

    - RESOLVED: ATI does not have a problem with the copyright issue.

 2. The EXT version of the spec does not multiply the output by
    RGB_SCALE_ARB and ALPHA_SCALE_ARB. There is no reason to impose this
    restriction since it makes the scale operations non-orthogonal.
    Should the enum values for the new tokens in this extension should
    be the same as the original EXT version?

    - RESOLVED: No.

 3. How exactly is this ARB extension different from the EXT version?

    - RESOLVED:  Scaling by 2.0 and 4.0 is supported by the ARB version,
      but not the EXT version (as noted above).  Note that when
      DOT3_RGBA_ARB is used, the alpha component result is scaled
      based on the RGB scale factor rather than the alpha scale factor
      (the COMBINE_ALPHA_ARB function and scale factor are ignored).
      The COMBINE_ALPHA_ARB mode is ignored in the EXT version and the
      previous alpha is passed through; however, the ARB version abides
      by the COMBINE_ALPHA_ARB setting.
```

New Procedures and Functions

```
    None
```

New Tokens

```
    Accepted by the <params> parameter of TexEnvf, TexEnvi, TexEnvfv,
    and TexEnviv when the <pname> parameter value is COMBINE_RGB_ARB

        DOT3_RGB_ARB                                    0x86AE
        DOT3_RGBA_ARB                                   0x86AF
```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

```
    None
```

Additions to Chapter 3 of the GL Specification (Rasterization)

```
    Added to table 3.20 of the ARB_texture_env_combine spec:

        COMBINE_RGB_ARB         Texture Function
        ---------------         ----------------
        DOT3_RGB_ARB            4*((Arg0_r - 0.5)*(Arg1_r - 0.5) +
                                   (Arg0_g - 0.5)*(Arg1_g - 0.5) +
                                   (Arg0_b - 0.5)*(Arg1_b - 0.5))

                                This value is placed into all three
                                r,g,b components of the output.

        DOT3_RGBA_ARB           4*((Arg0_r - 0.5)*(Arg1_r - 0.5) +
                                   (Arg0_g - 0.5)*(Arg1_g - 0.5) +
                                   (Arg0_b - 0.5)*(Arg1_b - 0.5))

                                This value is placed into all four
                                r,g,b,a components of the output. Note
                                that the result generated from
                                COMBINE_ALPHA_ARB function is ignored.

Version

    Based on the ATI_texture_float extension, verion 4

    Last Modified Date: July 6, 2006
    Version: 6

Number

    ARB Extension #41

Dependencies

    This extension is written against the OpenGL 2.0 Specification
    but will work with the OpenGL 1.5 Specification.

    OpenGL 1.1 or EXT_texture is required.

    This extension interacts with ARB_color_buffer_float.

Overview

    This extension adds texture internal formats with 16- and 32-bit
    floating-point components. The 32-bit floating-point components
    are in the standard IEEE float format. The 16-bit floating-point
    components have 1 sign bit, 5 exponent bits, and 10 mantissa bits.
    Floating-point components are clamped to the limits of the range
    representable by their format.

IP Status

    SGI owns US Patent #6,650,327, issued November 18, 2003. SGI
    believes this patent contains necessary IP for graphics systems
    implementing floating point (FP) rasterization and FP framebuffer

capabilities.

SGI will not grant the ARB royalty-free use of this IP for use in OpenGL, but will discuss licensing on RAND terms, on an individual basis with companies wishing to use this IP in the context of conformant OpenGL implementations. SGI does not plan to make any special exemption for open source implementations.

Contact Doug Crisman at SGI Legal for the complete IP disclosure.

Issues

1. *How is this extension different from the ATI_texture_float extension?*

   This extension expands on the definition of float16 values and adds a query to determine if the components of a texture are stored as floats.

2. *Should the new names of the internal formats be changed to a different spelling?*

   RESOLVED: Internal format names have been updated to the same convention as the EXT_framebuffer_object extension.

3. *Is it allowable for an implementation to fall back to a non floating-point internal format if it does not support the requested format?*

   RESOLVED: No. An application that requests floating-point formats should expect to get them. Only the precision of the internal format can be changed. When this extension is promoted to the core, this issue may need to be readdressed.

4. *Do the new internal formats apply to any other commands?*

   RESOLVED: Since color tables support the same <internalFormat> values as textures, they are also extended with this extension, except the individual component types cannot be queried.

5. *Are the floating-point values clamped before they are stored into the texture memory or color tables?*

   RESOLVED: The values are clamped to the representatable range of the storage format. Overflows could produce +/-INF and underflows could produce denorms or zero. This matches the behavior of the ATI extension.

6. *Should this extension modify the clamping of the texture border color components?*

   RESOLVED: Yes. The border color components are unclamped. When used, the border color components are interpreted in a manner consistent with the texture's internal format. For fixed-point textures, this means that the border color is clamped to [0, 1] when used.

7. Are floating-point values clamped for the fixed-function GL?

RESOLVED: This extension introduces texel values that can be outside [0, 1]. No clamping occurs to these values during texture filtering. For the fixed-function pipeline, the filtered texel is now clamped before it is used for texture environment blending. The ARB_color_buffer_float extension can be used to control this clamping. For the programmable pipelines, no clamping occurs.

8. Should the query for the border color return the unclamped values?

RESOLVED: There is language in the ARB_color_buffer_float extension that handles this. Since there is no clamp control in this specification, it would be hard to do anything other than return the clamped values.

New Procedures and Functions

None

New Tokens

Accepted by the <value> parameter of GetTexLevelParameter:

TEXTURE_RED_TYPE_ARB	0x8C10
TEXTURE_GREEN_TYPE_ARB	0x8C11

LUMINANCE32F_ARB	0x8818
LUMINANCE_ALPHA32F_ARB	0x8819
RGBA16F_ARB	0x881A
RGB16F_ARB	0x881B
ALPHA16F_ARB	0x881C
INTENSITY16F_ARB	0x881D
LUMINANCE16F_ARB	0x881E
LUMINANCE_ALPHA16F_ARB	0x881F

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

Add a new Section 2.1.2, (p. 6):

2.1.2 16-Bit Floating-Point Numbers

A 16-bit floating-point number has a 1-bit sign (S), a 5-bit exponent (E), and a 10-bit mantissa (M). The value of a 16-bit floating-point number is determined by the following:

```
    (-1)^S * 0.0,                        if E == 0 and M == 0,
    (-1)^S * 2^-14 * (M / 2^10),         if E == 0 and M != 0,
    (-1)^S * 2^(E-15) * (1 + M/2^10),    if 0 < E < 31,
    (-1)^S * INF,                        if E == 31 and M == 0, or
    NaN,                                 if E == 31 and M != 0,
```

where

```
    S = floor((N mod 65536) / 32768),
    E = floor((N mod 32768) / 1024), and
    M = N mod 1024.
```

Implementations are also allowed to use any of the following alternative encodings:

```
    (-1)^S * 0.0,                        if E == 0 and M != 0,
    (-1)^S * 2^(E-15) * (1 + M/2^10),    if E == 31 and M == 0, or
    (-1)^S * 2^(E-15) * (1 + M/2^10),    if E == 31 and M != 0,
```

Any representable 16-bit floating-point value is legal as input to a GL command that accepts 16-bit floating-point data. The result of providing a value that is not a floating-point number (such as infinity or NaN) to such a command is unspecified, but must not lead to GL interruption or termination. Providing a denormalized number or negative zero to GL must yield predictable results.

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

Modify Section 3.6.3 (Pixel Transfer Modes), p. 116

(modify first paragraph, p. 118) The specified image is taken from memory and processed just as if DrawPixels were called, stopping after the final expansion to RGBA. The R, G, B, and A components of each pixel are then scaled by the four COLOR TABLE SCALE parameters and biased by the four COLOR TABLE BIAS parameters. These parameters are set by calling ColorTableParameterfv as described below. If fragment color clamping is enable or the <internalformat> is fixed-point, the components are clamped to [0, 1]. Otherwise, the components are not modified.

Modify Section 3.8.1 (Texture Image Specification), p. 150

(modify second paragraph, p. 151) The selected groups are processed exactly as for DrawPixels, stopping just before final conversion. For R, G, B, and A, if the <internalformat> of the texture is fixed-point, the components are clamped to [0, 1]. Otherwise, the components are not modified. The depth value so generated is clamped to [0, 1].

(modify the second paragraph, p. 152) The internal component resolution is the number of bits allocated to each value in a texture image. If <internalformat> is specified as a base internal format, the GL stores the resulting texture with internal component resolutions of its own choosing. If a sized internal format is specified, the mapping of the R, G, B, A, and depth values to texture components is equivalent to the mapping of the corresponding base internal format's components, as specified in table 3.15, the type (unsigned int, float, etc.) is assigned the same type specified by <internalFormat>, and the memory allocation per texture component is assigned by the GL to match the allocations listed in table 3.16 as closely as possible. (The definition of closely is left up to the implementation. Implementations are not required to support more than one resolution of each type (unsigned int, float, etc.) for each base internal format.) If a compressed internal format is specified, the mapping of the R, G, B, A, and depth values to texture components is equivalent to the mapping of the corresponding base internal format's components, as specified in table 3.15. The specified image is compressed using a (possibly lossy) compression algorithm chosen by the GL.

(add the following to table 3.16, p. 154)

Sized Internal Format	Base Internal Format	R bits	G bits	B bits	A bits	L bits	I bits
RGBA32F_ARB	RGBA	f32	f32	f32	f32		
RGB32F_ARB	RGB	f32	f32	f32			
ALPHA32F_ARB	ALPHA				f32		
INTENSITY32F_ARB	INTENSITY						f32
LUMINANCE32F_ARB	LUMINANCE					f32	
LUMINANCE_ALPHA32F_ARB	LUMINANCE_ALPHA				f32	f32	
RGBA16F_ARB	RGBA	f16	f16	f16	f16		
RGB16F_ARB	RGB	f16	f16	f16			
ALPHA16F_ARB	ALPHA				f16		
INTENSITY16F_ARB	INTENSITY						f16
LUMINANCE16F_ARB	LUMINANCE					f16	
LUMINANCE_ALPHA16F_ARB	LUMINANCE_ALPHA				f16	f16	

Table 3.16: Correspondence of sized internal formats to base internal formats, and desired component resolutions for each sized internal format. The notation <f16> and <f32> imply 16- and 32-bit floating-point, respectively.

Modify Section 3.8.4 (Texture Parameters), p. 166

(remove TEXTURE_BORDER_COLOR from end of first paragraph, p. 166)

... If the values for TEXTURE_BORDER_COLOR or the value for TEXTURE_PRIORITY are specified as integers, the conversion for signed integers from table 2.9 is applied to convert this value to floating-point. Regardless of the original data type, the value for TEXTURE_PRIORITY is clamped to lie in [0, 1].

... If the value for TEXTURE_PRIORITY is specified as an integer, the conversion for signed integers from table 2.9 is applied to convert this value to floating-point, followed by clamping the value to lie in [0, 1].

Modify Section 3.8.8 (Texture Minification), p. 170

(modify last paragraph, p. 174) ... If the texture contains color components, the values of TEXTURE BORDER COLOR are interpreted as an RGBA color to match the texture's internal format in a manner consistent with table 3.15. The border values for texture components stored as fixed-point values are clamped to [0, 1] before they are used. If the texture contains depth ...

Modify Section 3.8.11 (Texture State and Proxy State) p. 178

(modify the first section, p. 178) ...Each array has associated with it a width, height (two- and three-dimensional and cubemap only), and depth (three-dimensional only), a border width, an integer describing the internal format of the image, six integer values describing the resolutions of each of the red, green, blue, alpha, luminance, and intensity components of the image, six values that describe the type (unsigned int, floats, etc.) of each of the red, green, blue, alpha, luminance, and intensity components of the image, a boolean describing whether the image is compressed or not, and an integer size of a compressed image. Each initial...

(modify the first paragraph, p. 179) ...Each proxy array includes width, height (two- and three- dimensional arrays only), depth (three-dimensional arrays only), border width, and internal format state values, as well as state for the red, green, blue, alpha, luminance, and intensity component resolutions and types (unsigned int, floats, etc.). Proxy arrays do not include image data, nor do they include texture properties. When TexImage3D is executed with target specified as PROXY TEXTURE 3D, the three-dimensional proxy state values of the specified level-of-detail are recomputed and updated. If the image array would not be supported by TexImage3D called with target set to TEXTURE 3D, no error is generated, but the proxy width, height, depth, border width, and component resolutions are set to zero, and the component types are set to NONE. If the image...

Modify Section 3.8.13 (Texture Environments and Functions), p.182

(replace the sixth paragraph of p. 183) All of these color values are clamped to the range [0, 1]. The texture functions are specified in tables 3.22, 3.23, and 3.24.

Additions to Chapter 4 of the OpenGL 2.0 Specification (Per-Fragment Operations and the Frame Buffer)

None

Additions to Chapter 5 of the OpenGL 2.0 Specification (Special Functions)

None

Additions to Chapter 6 of the OpenGL 2.0 Specification (State and State Requests)

Modify Section 6.1.3 (Enumerated Queries), p. 246

(modify second paragraph, p. 247) For texture images with uncompressed internal formats, queries of <value> of TEXTURE_RED_TYPE_ARB, TEXTURE_GREEN_TYPE_ARB, TEXTURE_BLUE_TYPE_ARB, TEXTURE_ALPHA_TYPE_ARB, TEXTURE_LUMINANCE_TYPE_ARB, TEXTURE_INTENSITY_TYPE_ARB, and TEXTURE_DEPTH_TYPE_ARB, return either NONE, UNSIGNED_NORMALIZED_ARB, or FLOAT indicating how the components are stored, and the queries of <value> of TEXTURE_RED_SIZE, TEXTURE_GREEN_SIZE, TEXTURE_BLUE_SIZE, TEXTURE_ALPHA_SIZE, TEXTURE_LUMINANCE_SIZE, TEXTURE_DEPTH_SIZE, and TEXTURE_INTENSITY_SIZE return the actual resolutions of the stored image array components, not the resolutions specified when the image array was defined.

Additions to the AGL/GLX/WGL Specifications

None

Dependencies on ARB_color_buffer_float extension

The ARB_color_buffer_float extension allows clamping to be controlled in various parts of the GL. Specifically, clamping of filtered texel values used for texture environment blending can be disable.

Errors

None

New State

(Table 6.17, p. 278) add the following entries:

Get Value	Type	Get Command	Minimum Value	Description	Section	Attribute

Revision History

Rev.	Date	Author	Changes
1	2/26/04	kirkland	Initial version based on the ATI extension.

```
    2   3/11/04  kirkland   Updated language for float16 number
                            handling.
                            Added bit encodings for half values.
                            Added an issue for color tables.
                            Added separate queries for component
                            types.
                            Changed the internal format names to
                            match the uber buffer extension.
                            Added language to not allow textures to
                            change the type of the internal formats,
                            only the precision.

    3   7/23/04  kirkland   Added alternative encodings options for
                            float16 format.

    4   9/17/04  kirkland   Updated to reference the OpenGL 2.0 spec.
                            Added interaction with clamp control.
                            Removed the clamping of color table data.

    5   10/1/04  Kirkland   Updated IP section.
                            Reviewed by the ARB and closed all
                            UNRESOLVED issues.

    6    7/6/06  pbrown     Fixed broken language for border color
                            handling.  TexParameteriv border colors
                            should still be converted to integer; we
                            only intended to remove the [0,1] clamping.
```

Name

    ARB_texture_mirrored_repeat

Name Strings

    GL_ARB_texture_mirrored_repeat

Status

    Complete. Approved by ARB on October 16, 2001.

Version

    Last modified date: 2001/09/20

Number

    ARB Extension #21

Dependencies

    This extension is written against the OpenGL 1.3 Specification.
    However, this extension does not require OpenGL 1.3.

Overview

    ARB_texture_mirrored_repeat extends the set of texture wrap modes to
    include a mode (GL_MIRRORED_REPEAT_ARB) that effectively uses a texture
    map twice as large at the original image in which the additional half,
    for each coordinate, of the new image is a mirror image of the original
    image.

    This new mode relaxes the need to generate images whose opposite edges
    match by using the original image to generate a matching "mirror image".

Issues

     1. The spec clamps the final (u,v) coordinates to the range [0.5, 2^n-0.5].
        This will produce the same effect as trapping a sample of the border texel
        and using the corresponding edge texel. The choice of technique is purely
        an implementation detail.

     2. The IBM_texture_mirrored_repeat extension inadvertantly used an HP
        enumerant value (0x8370) allocated by HP as an interleaved array format.
        Should the enumerant value be changed if this becomes an ARB extension?

        No, it is not worth the confusion created by having two different
        enumerant value for the same token.

     3. Should additional mirroring functions be added to this extension and
        perhaps rename it to ARB_texture_mirror. For example, include the two
        mirror modes (MIRROR_CLAMP_ATI and MIRROR_CLAMP_TO_EDGE_ATI) provided
        for in the GL_ATI_texture_mirror_once extension.

    No, these extensions are not interdependent and inclusion of the
    mirror once will likely hinder the adoption of this extension.

New Procedures and Functions

    None

New Tokens

    Accepted by the <param> parameter of TexParameteri and TexParameterf,
    and by the <params> parameter of TexParameteriv and TexParameterfv, when
    their <pname> parameter is TEXTURE_WRAP_S, TEXTURE_WRAP_T, or
    TEXTURE_WRAP_R:

```
      GL_MIRRORED_REPEAT_ARB                   0x8370
```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

    None.

Additions to Chapter 3 of the GL Specification (Rasterization)

  Modify Table 3.19, editing only the following lines:

```
    Name              Type      Legal Values
    ==============    =======   ====================
    TEXTURE_WRAP_S    integer   CLAMP, CLAMP_TO_EDGE, REPEAT,
                                CLAMP_TO_BORDER_ARB, MIRRORED_REPEAT_ARB
    TEXTURE_WRAP_T    integer   CLAMP, CLAMP_TO_EDGE, REPEAT,
                                CLAMP_TO_BORDER_ARB, MIRRORED_REPEAT_ARB
    TEXTURE_WRAP_R    integer   CLAMP, CLAMP_TO_EDGE, REPEAT,
                                CLAMP_TO_BORDER_ARB, MIRRORED_REPEAT_ARB
```

  Add to end of Section 3.8.5 (Subsection "Texture Wrap Modes")

    If TEXTURE_WRAP_S, TEXTURE_WRAP_T, or TEXTURE_WRAP_R is set to
    MIRRORED_REPEAT_ARB, the s (or t or r) coordinate is converted to:

```
        s - floor(s),           if floor(s) is even, or
        1 - (s - floor(s)),     if floor(s) is odd.
```

    The converted s (or t or r) coordinate is then clamped
    as described for CLAMP_TO_EDGE texture coordinate clamping.

Status

    Approved by the ARB on June 11, 2003.

Version

    Date: May 14, 2004
    Revision: 1.0

Number

    ARB Extension #34

Dependencies

    Written based on the OpenGL 1.4 specification.

    ARB_texture_mirrored_repeat (and IBM_texture_mirrored_repeat)
    affects the definition of this extension.

    ARB_texture_border_clamp affects the definition of this extension.

    EXT_texture_compression_s3tc and NV_texture_compression_vtc affect
    the definition of this extension.

Overview

    Conventional OpenGL texturing is limited to images with
    power-of-two dimensions and an optional 1-texel border.
    ARB_texture_non_power_of_two extension relaxes the size restrictions
    for the 1D, 2D, cube map, and 3D texture targets.

    There is no additional procedural or enumerant api introduced by this
    extension except that an implementation which exports the extension
    string will allow an application to pass in texture dimensions for
    the 1D, 2D, cube map, and 3D targets that may or may not be a power
    of two.

    An implementation which supports relaxing traditional GL's
    power-of-two size restrictions across all texture targets will export
    the extension string: "ARB_texture_non_power_of_two".

    When this extension is supported, mipmapping, automatic mipmap
    generation, and all the conventional wrap modes are supported for
    non-power-of-two textures

Issues

1. What should this extension be called?

STATUS: RESOLVED

RESOLUTION: ARB_texture_non_power_of_two. Conventional OpenGL textures are restricted to size dimensions that are powers of two.

The phrases POT (power of two) and NPOT (non-power of two) textures are used in the Overview and Issues section of this specification, but notice these terms are never required in the actual extension language to amend the core specification.

2. Should any enable or other state change be required to relax the texture dimension restrictions?

STATUS: RESOLVED

RESOLUTION: No. The restrictions on texture dimensions in the core OpenGL specification are enforced by errors. Extensions are free to make legal and defined the error behavior of extensions. This extension is really no different in that respect.

The argument for having an enable to "unlock" more generalized texture dimensions is that it avoids developers accidently releasing applications developed on an OpenGL implementation supporting this extension and unintentionally using NPOT textures. This situation exists in theory with other extensions that do not require new entry points or enumerants to operate (think of NV_blend_square). The real responsibility falls on developers to not use extensions unless the implementation advertises support for the extension and do proper testing to ensure this is really the case.

An additional issue with not having an enable to "unlock" this feature concerns the cases where existing apps might actually be relying on the current error condition to tell them what to do, but might not be able to handle the "new" success this extension would create. However, this seems to be limited to apps that are explicitly checking for implementation correctness (like a conformance test) and this does not seem to be a typical problem for "real-world" applications. The working group members agreed that it is acceptable to require those few apps which fall into this category to be updated in the context of this extension.

3. Should this extension be limited to a subset of conventional texture targets?

STATUS: RESOLVED

SUGGESTION: No. This extension should apply to 1D, 2D, 3D, and cube map textures (all supported by OpenGL 1.4) but this extension does NOT extend or otherwise affect the EXT_texture_rectangle extension's TEXTURE_RECTANGLE_EXT target.

```
  One early point of debate was whether we should have a single
  unified extension which lifted the power of two restrictions from
  all targets, or whether we should have individual target specific
  extensions.   For example, one could imagine separate extensions for
  ARB_texture_non_power_of_two_2d, ARB_texture_non_power_of_two_3d,
  ARB_texture_non_power_of_two_cube_map.

  The advantages of the separate extension approach are to allow IHV's
  to choose which pieces of functionality to support independently.
  The advantages of the single extension approach is to have a
  simpler and more forward looking extension.
```

4. Are cube map texture images still required to be square when this extension is supported?

```
  STATUS: RESOLVED

  RESOLUTION:  Yes.  But while the width and height of each level
  must be equal, they can be NPOT.
```

5. How is a conventional NPOT target different from the texture rectangle target?

```
  STATUS: RESOLVED

  RESOLUTION:
  The biggest practical difference is that coventional targets use
  normalized texture coordinates (ie, [0..1]) while the texture
  rectangle target uses unnormalized (ie, [0..w]x[0..h]) texture
  coordinates.

  Differences include:

  + In ARB_texture_non_power_of_two:
    * mipmapping is allowed, default filter remains unchanged.
    * all wrap modes are allowed, default wrap mode remains unchanged.
    * borders are supported.
    * paletted textures are not unsupported.
    * texture coordinates are addressed parametrically [0..1],[0..1]
  + In EXT_texture_rectangle:
    * mipmapping is not allowed, default filter is changed to LINEAR.
    * only CLAMP* wrap modes are allowed, default is CLAMP_TO_EDGE.
    * borders are not supported.
    * paletted textures are unsupported.
    * texture coordinates are addressed non-parametrically [0..w],[0..h].
```

6. What is the dimension reduction rule for each successively smaller mipmap level?

STATUS: RESOLVED

RESOLUTION: Each successively smaller mipmap level is half the size of the previous level, but if this half value is a fractional value, you should round down to the next largest integer. Essentially:

```
max(1, floor(w_b / 2^i)) x
   max(1, floor(h_b / 2^i)) x
      max(1, floor(d_b / 2^i))
```

where i is the ith level beyond the 0th level (the base level).

This is a "floor" convention. An alternative is a "ceiling" convention.

The primary reason to favor the floor convention is that Direct3D uses the floor convention.

Also, the "ceiling" convention potentially implies one more mipmap level than the "floor" convention.

Some regard the "ceiling" convention to have nicer properties with respect to making sure that each level samples at at least 2x the frequency of the next level. This can reduce the chances of sampling artifacts. However, it's probably not worth diverging from the Direct3D convention just for this. A more sophisticated downsampling algorithm (using a larger kernel perhaps) during mipmap level generation can help reduce artifacts related to using the "floor" convention.

The "floor" convention has a relatively straightforward way to evaluate (with integer math) means to determine how many mipmap levels are required for a complete pyramid:

```
numLevels = 1 + floor(log2(max(w, h, d)))
```

The "floor" convention can be evaluated incrementally with the following recursion:

```
 nextLODdim = max(1, currentLODdim >> 1)
```

where currentLODdim is the dimension of a level N and nextLODdim is the dimension of level N+1. The recursion stops when level numLevels-1 is reached.

Other compromise rules exist such as "round" (floor(x+0.5)). Such a hybrid approach make it more difficult to compute how many mipmap levels are required for a complete pyramid.

Note that this extension is compatible with supporting other rules because it merely relaxes the error and completeness conditions for mipmaps. At the same time, it makes sense to provide developers a single consistent rule since developers are unlikely to want to generate mipmaps for different rules unnecessarily. One reasonable rule is sufficient and preferable, and the "floor" convention is the best choice.

7. Should the LOD for filtering (rho) be computed differently for NPOT textures?

STATUS: RESOLVED

RESOLUTION: No (though, ideally, the answer would be "yes slightly somehow"). The core OpenGL specification already allows that the ideal computation of rho (even for POT textures) is "often impractical to implement". The "ceiling" convention adds one more mipmap level for NPOT textures so at extreme minification, the "ceiling" convention may be somewhat sharper than ideal (whereas "floor" would be blurrier).

This excess bluriness should only be significant at the smallest (blurriest) mipmap levels where it should be quite difficult to notice for properly downsampled mipmap images.

8. Should there be any restrictions on the wrap modes supported for NPOT textures?

STATUS: RESOLVED

RESOLUTION: No restrictions; all existing wrap modes (GL_REPEAT, GL_CLAMP, GL_CLAMP_TO_EDGE, GL_CLAMP_TO_BORDER, and GL_MIRRORED_REPEAT) should "just work" with NPOT textures.

The difficult part of this requirement is to compute "mod w_i" (or h_i or d_i) rather than simply "mod 2^n" (or 2^m or 2^l) for the GL_REPEAT wrap mode (GL_MIRRORED_REPEAT may also be an issue, but as defined by OpenGL 1.4, no "mod" math is required to implement the mirrored repeat wrap mode). REPEAT is too commonly used (indeed it is the default wrap mode) to exclude it for NPOT textures.

9. How does this extension interact with ARB_texture_compression?

STATUS: RESOLVED

RESOLUTION: It does not. ARB_texture_compression doesn't technically require that any compressed formats be supported. Implementations can choose to compress or not compress any particular texture.

While implementations may choose an internal component resolution and compressed format, the OpenGL 1.4 requires that the choice be a function only of the TexImage parameters. If an implementation chose not to compress NPOT textures, it might get into a situation where a 7x7 image wasn't compressed but its 4x4, 2x2, and 1x1 mipmaps were compressed. The result would be an inconsistent mipmap chain since the internal format of each level would not the same.

Therefore, an implementation must be able to handle the case where decisions it makes during image specification can be corrected appropriately at render time. This may mean that an implementation such as the one described above may need to tempoarily keep compressed and uncompressed images internally until the full mipmap stack can be examined or may need to decompress previously compressed images in order to recover.

10. How does this extension interact with specific texture compression extensions such as EXT_texture_compression_s3tc?

STATUS: RESOLVED

RESOLUTION: It does not. If both this extension and EXT_texture_compression_s3tc are supported, applications can safely load NPOT S3TC-compressed textures.

Textures are still decomposed into an array of 4x4 blocks. The compressed data for any texels outside the specified image dimensions are irrelevant and are effectively ignored, just as they are for the 1x1 and 2x2 mipmaps of a POT S3TC-compressed texture.

11. How is automatic mipmap generation affected by this extension?

STATUS: RESOLVED

RESOLUTION: It is not directly affected. If an implementation supports automatic mipmap generation, then mipmap generation must be supported even for NPOT textures.

Note however, that the OpenGL 1.4 specification recommends a "2x2 box filter" for the default filter. This is typo since a 2x2 box filter would be incorrect for 1D and 3D textures. With support for NPOT textures, this "2x2 box filter" becomes even more inappropriate. The wording should be changed to simply recommend a box filter where the dimensionality and filter size is assumed appropriate for the texture image dimensionality and size.

12. Are any edits required for Section 3.8.10 "Texture Completeness"?

STATUS: RESOLVED

RESOLUTION: No. This section references Section 3.8.8 for the allowed sequence of dimensions for completeness (rather than stating the requirements explicition in Section 3.8.10). The only difference between NPOT and POT textures is the allowable sequence of mipmap sizes, and in both cases, a smaller level is half the size of the larger (modulo rounding).

As with POT textures, a mipmap chain is consistent only if the correct sequence of sizes is found. As with POT textures, an attempt to load a mipmap that could never be part of a consistent mipmap chain should fail. For example, if an implementation supports textures with dimensions only up to 1024, an attempt to load level 2 with a 257x114 texture will fail because the smallest possible corresponding level 0 texture would have to be 1028x456.

13. The WGL_ARB_render_texture extension allows creating a pbuffer with the WGL_PBUFFER_LARGEST_ARB attribute. If this extension is present, should this attribute potentially return a NPOT pbuffer?

STATUS: UNRESOLVED

SUGGESTION: The WGL_ARB_render_texture specification appears to anticipate NPOT textures with this statement: "e.g. Both the width and height will be a power of 2 if the implementation only supports power of 2 textures." so I think the right thing to do is allow NPOT textures (of the proper aspect ratio) to be returned.

It is not entirely clear if this behavior is "safe" for preexisting applications that might not be aware of NPOT textures. The safe thing would be to add a WGL_PBUFFER_LARGEST_NPOT_ARB enumerant that could return NPOT textures and require that the existing WGL_PBUFFER_LARGEST_ARB enumerant always return POT textures.

New Procedures and Functions

None

New Tokens

None

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

None

Additions to Chapter 3 of the GL Specification (Rasterization)

-- Section 3.8.1 "Texture Image Specification"

Replace the discussion of the border parameter with:

"The border argument to TexImage3D is a border width. The significance of borders is described below. The border width affect the dimensions of the texture image; it must be the case that

$$w_s = w_i + 2 b_s \qquad (3.13)$$

$$h_s = h_i + 2 b_s \qquad (3.14)$$

$$d_s = d_i + 2 b_s \qquad (3.15)$$

where w_s, h_s, and d_s are the specified image width, height, and depth, and w_i, h_i, and d_i are the dimensions of the texture image internal to the border. If w_i, h_i, or d_i are less than zero, then the error INVALID_VALUE is generated.

-- Section 3.8.8 "Texture Minification"

In the subsection "Scale Factor and Level of Detail"...

Replace the sentence defining the u, v, and w functions with:

"Let u(x,y) = w_i * s(x,y), v(x,y) = h_i * t(x,y), and w(x,y) = d_i * r(x,y), where w_i, h_i, and d_i are as defined by equations 3.13, 3.14, and 3.15 with w_s, w_s, and d_s equal to the width, height, and depth of the image array whose level is TEXTURE_BASE_LEVEL."

Replace 2^n, 2^m, and 2^l with w_i, h_i, and d_i in Equations 3.19, 3.20, and 3.21.

```
    { floor(u),   s < 1
i = {                               (3.19)
    { w_i - 1,    s = 1

    { floor(u),   t < 1
j = {                               (3.20)
    { h_i - 1,    t = 1

    { floor(u),   r < 1
k = {                               (3.21)
    { d_i - 1,    r = 1
```

Replace 2^n, 2^m, and 2^l with w_i, h_i, and d_i in the equations for computing i_0, j_0, k_0, i_1, j_1, and k_1 used for LINEAR filtering.

```
      { floor(u - 1/2) mod w_i,   TEXTURE_WRAP_S is REPEAT
i_0 = {
      { floor(u - 1/2),           otherwise

      { floor(v - 1/2) mod h_i,   TEXTURE_WRAP_T is REPEAT
j_0 = {
      { floor(v - 1/2),           otherwise

      { floor(w - 1/2) mod d_i,   TEXTURE_WRAP_R is REPEAT
k_0 = {
      { floor(w - 1/2),           otherwise

      { (i_0 + 1) mod w_i,        TEXTURE_WRAP_S is REPEAT
i_1 = {
      { i_0 + 1,                  otherwise

      { (j_0 + 1) mod h_i,        TEXTURE_WRAP_T is REPEAT
j_1 = {
      { j_0 + 1,                  otherwise

      { (k_0 + 1) mod d_i,        TEXTURE_WRAP_R is REPEAT
k_1 = {
      { k_0 + 1,                  otherwise
```

In the subsection "Mipmapping"...

Replace the last sentence of the first paragraph with:

"If the image array of level level_base, excluding its border, has dimensions w_b x h_b x d_b, then there are floor(log2(max(w_b, h_b, d_b))) + 1 image arrays in the mipmap. Numbering the levels such that level level_base is the 0th level, the ith array has dimensions

```
  max(1, floor(w_b / 2^i)) x
    max(1, floor(h_b / 2^i)) x
      max(1, floor(d_b / 2^i))
```

until the last array is reached with dimension 1 x 1 x 1."

Replace the second sentence of the second paragraph with:

"Level-of-detail numbers proceed from level_base for the original texture array through p = floor(log2(max(w_b, h_b, d_b))) + level_base with each unit increase indicating an array of half the dimensions of the previous one (rounded down to the next integer if fractional) as already described."

In the subsection "Automatic Mipmap Generation"...

Replace the second sentence of the third paragraph with:

"No particular filter algorithm is required, though a box filter is recommended as the default filter."

-- Section 3.8.10 "Texture Completeness"

In the subsection "Effects of Completeness on Texture Image Specification"...

Replace the last sentence with:

"A mipmap complete set of arrays is equivalent to a complete set of arrays where level_base = 0 and level_max = 1000, and where, excluding borders, the dimensions of the image array being created are understood to be half the corresponding dimensions of the next lower numbered array (rounded down to the next integer if fractional)."

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

None

Additions to Chapter 5 of the GL Specification (Special Functions)

None

Additions to the GLX Specification

None

Additions to the EXT_texture_compression_s3tc and NV_texture_compression_vtc Specification

```
    Add this paragraph:

    "For a compressed texture where w_i != 2^m OR h_i != 2^n OR d_i != 2^l
    for some integer value of m, n, and l, the 4x4 tiles are assumed to be
    aligned to u=0, v=0, w=0 origin in texel space.  For such compressed
    textures, this implies that texels in regions of tiles beyond the
    edges u=w_i, v=h_i, and w=d_i will not be sampled explicitly."
```

GLX Protocol

```
    None
```

Errors

```
    Various errors are ELIMINATED when this extension is supported as
    noted.

    INVALID_VALUE is NO LONGER generated by TexImage1D or glCopyTexImage1D
    if width is not zero or cannot be represented as 2^n+2(border)
    for some integer value of n.

    INVALID_VALUE is NO LONGER generated by TexImage2D or glCopyTexImage2D
    if width or height is not zero or cannot be represented as
    2^n+2(border) for some integer value of n.

    INVALID_VALUE is NO LONGER generated by TexImage3D if width, height,
    or depth is not zero or cannot be represented as 2^n+2(border)
    for some integer value of n.

Revision History

```
    Date 05/14/2004
    Revision: 1.0
       -  Formated text for 72 column convention
       -  Fixed date for last revision
       -  fix "Image2d" typo

    Date: 03/23/2004
    Revision: 1.0
        - Formulas for computing the dimensions of mipmap sizes based
          on the base level size should involve 2^i (not i^2)
    Date: 09/11/2003
    Revision: 1.0
        - allow zero (instead of just positive values before) when
          specifying the width, height, and depth of texture image
          dimensions; this is to avoid an inconsistency with the
          sample implementation

    Date: 05/29/2003
    Revision: 0.10
        - removed "@" language for target specific behavior, the spec
          now treats all targets uniformly

    Date: 05/21/2003
    Revision: 0.9
        - fixed typo: ARB/IBM_mirrored_repeat should have been
          ARB/IBM_texture_mirrored_repeat
        - fixed various other minor typos, duplicated words, etc.
        - added a line to issue #6 regarding suggesting use of a
          larger kernel when downsampling using the floor convention
        - coalesced the equations that used 3 2-term max equations into
          single 3-term max equations for clarity
        - fixed two more typos where "ceil" should have been "floor"
        - refer to ARB_texture_rectangle as EXT_texture_rectangle
          (this may change back when/if back extension becomes ARB'ified)

    Date: 05/10/2003
    Revision: 0.8
        - additional additional names to contributors list
        - clarified language describing resolution of issues #9,10,11

    Date: 05/08/2003
    Revision: 0.7
        - very minor language update to overview section regarding
          exporting of ARB_texture_non_power_of_two string
        - fixed another two places where it said we should round up
          instead of down (in section 3.8.10 "Texture Completeness",
          and in section 3.8.8 "Texture Minification")
        - mark the regions of the spec affected by the decision to
          use separate strings per texture target with the "@" symbol.
          This is temporary until issue #3 is resolved.
        - resolved issues 9,10,11,12

    Date: 05/08/2003
    Revision: 0.6
        - updated revision history and coalesced revision notes from
          various specs
        - fixed typo in issue #5 ("2d" --> "non_power_of_two")
        - clarified the discussion in issue #3 as the langage was a
          little confusing in parts.
        - explicitly refer to the cube map targets in section 3.8.1
          instead of using the "made up" target TEXTURE_CUBE_MAP.
    Date: 05/06/2003
    Revision: 0.5
        - changed name of extension from ARB_texture_np2 to
          ARB_texture_non_power_of_two
        - added target specific extension strings
        - added more discussion to several issues based on feedback from
          the working group meetings
        - fixed several typos where INVALID_VALUE was INVALID_VALID
        - addressed typo in issue #6, it said you should round up,
          but really we agreed to round down when describing the mipmap
          stack (floor vs ceil convention).
        - resolved issues 1 - 8.

    Date: 04/24/2003
    Revision: 0.4 (jsandmel)
        - numbered issues list
        - additional discussion of several issues
        - added more explicit comparison of texture_rectangle and this
          proposal

    Date: 04/10/2003
    Revision: 0.3 (mjk)
        - integrates input from the ARB_texture_2d_np2 proposals.

    Date: 03/25/2003
    Revision: 0.1 (jsandmel)
        - draft proposal
        - deals with 2d targets only
        - named: ARB_texture_2d_np2
```

Notice

Status

    Complete. Approved by the ARB on June 8, 2004.

    Amended language re-voted by the ARB on November 3, 2005.

    Functionally identical to EXT_texture_rectangle and
    NV_texture_rectangle extensions currently shipping, except for
    the additions to the OpenGL Shading Language.

Version

    Date: October 4, 2005
    Revision: 1.21

Number

    ARB Extension #38

Dependencies

    OpenGL 1.1 is required

    OpenGL 1.4 (or ARB_texture_mirrored_repeat) affects the definition
    of this extension.

ARB_texture_non_power_of_two trivially affects the definition of this extension.

ATI_texture_mirror_once affects the definition of this extension.

EXT_paletted_texture affects the definition of this extension.

EXT_texture_compression_s3tc affects the definition of this extension.

EXT_texture_mirror_clamp affects the definition of this extension.

The OpenGL Shading Language specification (provided by OpenGL 2.0 and/or ARB_shader_objects) interacts with this extension.

This extension is written against the OpenGL 2.0 specification.

Overview

OpenGL texturing is limited to images with power-of-two dimensions and an optional 1-texel border. The ARB_texture_rectangle extension adds a new texture target that supports 2D textures without requiring power-of-two dimensions.

Non-power-of-two sized (NPOTS) textures are useful for storing video images that do not have power-of-two sized (POTS). Re-sampling artifacts are avoided and less texture memory may be required by using non-power-of-two sized textures. Non-power-of-two sized textures are also useful for shadow maps and window-space texturing.

However, non-power-of-two sized textures have limitations that do not apply to power-of-two sized textures. NPOTS textures may not use mipmap filtering; POTS textures support both mipmapped and non-mipmapped filtering. NPOTS textures support only the GL_CLAMP, GL_CLAMP_TO_EDGE, and GL_CLAMP_TO_BORDER wrap modes; POTS textures support GL_CLAMP_TO_EDGE, GL_REPEAT, GL_CLAMP, GL_MIRRORED_REPEAT, and GL_CLAMP_TO_BORDER (and GL_MIRROR_CLAMP_ATI and GL_MIRROR_CLAMP_TO_EDGE_ATI if ATI_texture_mirror_once is supported) . NPOTS textures do not support an optional 1-texel border; POTS textures do support an optional 1-texel border.

NPOTS textures are accessed by dimension-dependent (aka non-normalized) texture coordinates. So instead of thinking of the texture image lying in a [0..1]x[0..1] range, the NPOTS texture image lies in a [0..w]x[0..h] range.

This extension adds a new texture target and related state (proxy, binding, max texture size).

Issues

1) *Should rectangular textures simply be an extension to the 2D texture target that allows non-power-of-two widths and heights?*

No. The rectangular texture is an entirely new texture target type called GL_TEXTURE_RECTANGLE_ARB. This is because while the texture rectangle target relaxes the power-of-two dimensions requirements of the texture 2D target, it also has limitations such as the absence of both mipmapping and the GL_REPEAT and GL_MIRRORED_REPEAT wrap modes. Additionally, rectangular textures do not use [0..1] normalized texture coordinates.

The texture rectangle is an analogue to the pixel rectangle primitive (see section 3.6 titled "Pixel Rectangles" in the core specification) and the framebuffer. Just as the pixel rectangle primitive and the framebuffer are accessed by integer-ized dimension-dependent 2D coordinates, so is the texture rectangle. Just as pixel rectangles and the framebuffer do not have mipmaps, nor do texture rectangles.

2) *Should 1D, 2D, 3D, or cube map textures be allowed to be NPOTS by this extension?*

No. The ARB_texture_non_power_of_two extension relaxes the power-of-two restrictions for these conventional texture targets to support NPOTS while maintaining the normalized texture coordinates.

3) *How is the image of a rectangular texture specified?*

Using the standard OpenGL API for specifying a 2D texture image: glTexImage2D, glSubTexImage2D, glCopyTexImage2D, and glCopySubTexImage2D. The target for these commands is GL_TEXTURE_RECTANGLE_ARB though.

This is similar to how the texture cube map functionality uses the 2D texture image specification API though with its own texture target.

The texture target GL_TEXTURE_RECTANGLE_ARB should also be used for glGetTexImage, glGetTexLevelParameteriv, and glGetTexLevelParameterfv.

4) *Should anything be said about performance?*

No, but developers should not be surprised if conventional POTS textures will render slightly faster than texture rectangle textures. This is particularly likely to be true when texture rectangle textures are minified leading to texture cache thrashing due to lack of support for mipmaps.

5) *Is mipmap filtering permitted?*

Mipmap filtering is not permitted. Since this is the case the default minification filter for GL_TEXTURE_RECTANGLE_ARB targets is GL_LINEAR.

6) *What texture wrap modes are allowed and what is the default state?*

Only the GL_CLAMP, GL_CLAMP_TO_EDGE, and CLAMP_TO_BORDER wrap modes are allowed. CLAMP_TO_EDGE is the default state. GL_REPEAT and GL_MIRRORED_REPEAT are not supported with the GL_TEXTURE_RECTANGLE_ARB texture target.

```
 7) Are texture borders supported?

    Borders are not supported.

 8) Are paletted textures supported?

    Paletted rectangular textures are not supported.

 9) Can compressed texture images be specified for a rectangular texture?

    The generic texture compression internal formats introduced by
    ARB_texture_compression are supported for rectangular textures
    because the image is not presented as compressed data and the
    ARB_texture_compression extension always permits generic texture
    compression internal formats to be stored in uncompressed form.
    Implementations are free to support generic compression internal
    formats for rectangular textures if supported but such support is
    not required.

    This extensions makes a blanket statement that specific compressed
    internal formats for use with glCompressedTexImage<n>D are NOT
    supported for rectangular textures.  This is because several existing
    hardware implementations of texture compression formats such as S3TC
    are not designed for compressing rectangular textures.  This does
    not preclude future texture compression extensions from supporting
    compressed internal formats that do work with rectangular extensions
    (by relaxing the current blanket error condition).

10) How are rectangular textures enabled?

    Rectangular textures are enabled by enabling the
    GL_TEXTURE_RECTANGLE_ARB texture target via glEnable
    (GL_TEXTURE_RECTANGLE_ARB). This enable is prioritized above
    GL_TEXTURE_2D and below GL_TEXTURE_3D.

    From lowest priority to highest priority: GL_TEXTURE_1D,
    GL_TEXTURE_2D, GL_TEXTURE_RECTANGLE_ARB, GL_TEXTURE_3D,
    GL_TEXTURE_CUBE_MAP.

11) How are texture coordinates addressed for rectangular textures?

    Texture coordinates are addressed without being normalized from
    [0..1], instead [0..w] and [0..h] are used, where w and h are width
    and height of the texture respectively.

12) How should applications determine the available maximum texture
    dimensions available?

    Implementation dependent rectangular texture size limitations are
    queried using the GL_MAX_RECTANGLE_TEXTURE_SIZE_ARB parameter and
    may be different that standard texture size limits.

13) How does the handling of the R texture component differ from
    the handling of S and T?

    The R texture coordinate for rectangular textures is handled
    as it would be for standard two dimensional textures.  Thus the
```

coordinates range from [0..1] and the wrapping mode is unchanged from the default.

14) *Does this extension work with OpenGL 1.4's shadow mapping?*

Yes. The one non-obvious allowance to support OpenGL 1.4's shadow mapping is that the R texture coordinate wrap mode remains UNCHANGED for rectangular textures. Clamping of the R texture coordinate for rectangular textures uses the standard [0,1] interval rather than the [0,w_s] or [0,h_s] intervals as in the case of S and T. This is because R represents a depth value in the [0,1] range whether using a 2D or rectangular texture.

15) *How does this extension interact with GLSL based on the "OpenGL Shading Language Extension Conventions"?*

Unfortunately, this extension was specified and implemented contemporaneously with the GLSL Extension Conventions and because of this timing does not follow its guidance for #extension and adornment of new GLSL names. Because this extension has both an API interaction (adding a new rectangle texture target) and a GLSL interaction (functions and sampler types for accessing texture rectangles), you can't practically use the GLSL texture rectangle functionality without the API functionality. For this reason, detecting the GL_ARB_texture_rectangle string is sufficient for assuming the GLSL functionality is present.

Conceptually, you can consider the declaration #extension GL_ARB_texture_rectangle : require, to allow support for texture rectangles, to be implicitly prepended to every GLSL shader when ARB_texture_rectangle is advertised.

All future GLSL extensions should follow the "OpenGL Shading Language Extension Conventions" however.

16) *How can a GLSL shader tell if this extension is supported?*

"GL_ARB_texture_rectangle" preprocessor macro is predefined to be 1.

17) *Should GL_SAMPLER_2D_RECT_ARB and GL_SAMPLER_2D_RECT_SHADOW_ARB be returned by the "type" parameter of glGetActiveUniformARB when returning the type of a sampler2DRect or sampler2DRectShadow sampler uniform?*

Yes, there is already language in the ARB_shader_objects extension saying this so there's no additional language added to this extension. The language is missing from OpenGL 2.0 so we add the ARB_shader_objects language as part of this specification too.

18) *Can a shader still turn off support for this extension?*

Yes, a shader can still include all variations of #extension GL_ARB_texture_rectangle in its source code. This includes #extension GL_ARB_texture_rectangle : disable, to disable support for it.

New Procedures and Functions

None

New Tokens

Accepted by the <cap> parameter of Enable, Disable and IsEnabled; by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv and GetDoublev; and by the <target> parameter of BindTexture, GetTexParameterfv, GetTexParameteriv, TexParameterf, TexParameteri, TexParameterfv and TexParameteriv:

```
TEXTURE_RECTANGLE_ARB            0x84F5
```

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv and GetDoublev:

```
TEXTURE_BINDING_RECTANGLE_ARB    0x84F6
```

Accepted by the <target> parameter of GetTexLevelParameteriv, GetTexLevelParameterfv, GetTexParameteriv and TexImage2D:

```
PROXY_TEXTURE_RECTANGLE_ARB      0x84F7
```

Accepted by the <pname> parameter of GetBooleanv, GetDoublev, GetIntegerv and GetFloatv:

```
MAX_RECTANGLE_TEXTURE_SIZE_ARB   0x84F8
```

Accepted by the <target> parameter of GetTexImage, GetTexLevelParameteriv, GetTexLevelParameterfv, TexImage2D, CopyTexImage2D, TexSubImage2D and CopySubTexImage2D:

```
TEXTURE_RECTANGLE_ARB
```

Returned by <type> parameter of GetActiveUniform when the location <index> for program object <program> is of type sampler2DRect:

```
SAMPLER_2D_RECT_ARB              0x8B63
```

Returned by <type> parameter of GetActiveUniform when the location <index> for program object <program> is of type sampler2DRectShadow:

```
SAMPLER_2D_RECT_SHADOW_ARB       0x8B64
```

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

- (2.15.3, pg. 80-81) "Uniform Variables" under "Shader Variables"

Add SAMPLER_2D_RECT_ARB and SAMPLER_2D_RECT_SHADOW_ARB to the list of returned types in the sentence starting "The type returned can be any of ..."

- (2.15.4, pg. 86) "Texture Access" under "Shader Execution"

Replace the three bullets with the following language:

"...the results of a texture lookup are undefined if:

* The sampler used in a texture lookup function is of type sampler1D or sampler2D or sampler2DRect, and the texture object's internal format is DEPTH_COMPONENT, and the TEXTURE_COMPARE_MODE is not NONE.

* The sampler used in a texture lookup function is of type sampler1DShadow or sampler2DShadow or sampler2DRectShadow, and the texture object's internal format is DEPTH_COMPONENT, and the TEXTURE_COMPARE_MODE is NONE.

* The sampler used in a texture lookup function is of type sampler1DShadow or sampler2DShadow or sampler2DRectShadow, and the texture object's internal format is not DEPTH_COMPONENT."

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

These changes describe use of the TEXTURE_RECTANGLE_ARB texture target, supported formats, texture dimensions, and texture proxies:

- (3.6.3, pg. 118) "Pixel Transfer Modes" under "Color Table Specification" or the ColorTableEXT description in the EXT_paletted_texture specification

If EXT_paletted_texture is supported, add the following statement after paragraph 5 of the sub-section:

"The error INVALID_ENUM is generated if the target to ColorTable (or ColorTableEXT or the various ColorTable and ColorTableEXT alternative commands) is TEXTURE_RECTANGLE_ARB or PROXY_TEXTURE_RECTANGLE_ARB."

- (3.8.1, p. 151) "Texture Image Specification"

Change the first sentence of the fourth paragraph on this page to:

Textures with a base internal format of DEPTH COMPONENT are supported by texture image specification commands only if target is TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, PROXY_TEXTURE_1D, PROXY_TEXTURE_2D or PROXY_TEXTURE_RECTANGLE_ARB.

- (3.8.1, pg. 156) "Texture Image Specification"

Add a sentence to the middle of the 20th paragraph of the section (first paragraph on the page), directly after "... for image arrays of level 0 through k, where k is the log base 2 of MAX_TEXTURE_SIZE." reading:

"The maximum allowable width of a rectangular texture image, and the maximum allowable height of a rectangular texture image, must be at least the implementation-dependent value of MAX_RECTANGLE_TEXTURE_SIZE_ARB."

- (3.8.1, pg. 156) "Texture Image Specification"

In the 22th paragraph of this section (sixth paragraph on the page), change the sentence following "The command void TexImage2D ... a two-dimensional texture image." through the rest of the paragraph in the section describing two-dimensional texturing to read:

"<target> must be one of TEXTURE_2D for a two-dimensional texture, or one of TEXTURE_RECTANGLE_ARB for a rectangle texture, or one of TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, or TEXTURE_CUBE_MAP_NEGATIVE_Z for a cube map texture. Additionally, <target> may be either PROXY_TEXTURE_2D for a two-dimensional proxy texture, PROXY_TEXTURE_RECTANGLE_ARB for a rectangle proxy texture or PROXY_TEXTURE_CUBE_MAP for a cube map proxy texture as discussed in section 3.8.10. The other parameters match the corresponding parameters of TexImage3D."

Add this paragraph following the above two-dimensional texturing introduction, reading:

When the target is TEXTURE_RECTANGLE_ARB, the INVALID_VALUE error is generated if border is any value other than zero or the level is any value other than zero. In the case of a rectangular texture, ws and hs equal the specified width and height respectively of the rectangular texture image while ds is 1."

If EXT_paletted_texture is supported, add this paragraph too:

"Rectangular textures do not support paletted formats. The error INVALID_ENUM is generated if the target is TEXTURE_RECTANGLE_ARB or PROXY_TEXTURE_RECTANGLE_ARB and the format is COLOR_INDEX or the internal format is COLOR_INDEX or one of the COLOR_INDEX<n>_EXT internal formats."

- (3.8.1, pg. 156) "Texture Image Specification"

Amend the fourth paragraph on the page to read:

"A two-dimensional texture consists of a single two-dimensional texture image. A rectangle texture consists of a single 2D texture image. A cube map texture is a set of six two-dimensional texture images. The six cube map texture targets form a single cube map texture though each target names a distinct face of the cube map. The TEXTURE_CUBE_MAP_* targets listed above update their appropriate cube map face 2D texture image. The six cube map two-dimensional image tokens such as TEXTURE_CUBE_MAP_POSITIVE_X are used when specifying, updating, or querying one of a cube map's six two-dimensional images, but when enabling cube map texturing or binding to a cube map texture object (that is when the cube map is accessed as a whole as opposed to a particular two-dimensional image), the TEXTURE_CUBE_MAP target is specified."

- (3.8.1, pg. 157) "Texture Image Specification"

Append to the end of the third to the last paragraph in the section:

"A rectangular texture array has depth ds=1, with height hs and width ws defined by the specified image height and width parameters."

- (3.8.2, pg. 159) "Alternate Texture Image Specification Commands"

Add TEXTURE_RECTANGLE_ARB to the target list of the second paragraph of the section to say:

... "Currently, <target> must be TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, or TEXTURE_CUBE_MAP_NEGATIVE_Z." ...

- (3.8.2, pg. 160) "Alternate Texture Image Specification Commands"

Add TEXTURE_RECTANGLE_ARB to the target list in the fifth paragraph of the section to say:

... "Currently the target arguments of TexSubImage1D and CopyTexSubImage1D must be TEXTURE_1D, the <target> arguments of TexSubImage2D and CopyTexSubImage2D must be one of TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, or TEXTURE_CUBE_MAP_NEGATIVE_Z, and the <target> arguments of TexSubImage3D and CopyTexSubImage3D must be TEXTURE_3D." ...

Also append to the end of this paragraph:

"If target is TEXTURE_RECTANGLE_ARB and level is not zero, the error INVALID_VALUE is generated."

- (3.8.3, pg. 164) "Compressed Texture Images"

Add the following paragraph after the second paragraph in the section, which introduces the CompressedTexImage<n>D commands:

"The error INVALID_ENUM is generated if the target parameter to one of the CompressedTexImage<n>D commands is TEXTURE_RECTANGLE_ARB or PROXY_TEXTURE_RECTANGLE_ARB."

Add the following paragraph after introducing the CompressedTexSubImage<n>D commands:

"The error INVALID_ENUM is generated if the target parameter to one of the CompressedTexSubImage<n>D commands is TEXTURE_RECTANGLE_ARB or PROXY_TEXTURE_RECTANGLE_ARB."

- (3.8.4, pg. 166) "Texture Parameters"

Add TEXTURE_RECTANGLE_ARB to paragraph one to say:

... "<target> is the target, either TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, or TEXTURE_CUBE_MAP." ...

- (3.8.4, pg. 168) "Texture Parameters"

Add the following paragraph to the end of the section:

"Certain texture parameter values may not be specified for textures with a target of TEXTURE_RECTANGLE_ARB. The error INVALID_ENUM is generated if the target is TEXTURE_RECTANGLE_ARB and the TEXTURE_WRAP_S, TEXTURE_WRAP_T, or TEXTURE_WRAP_R parameter is set to REPEAT, MIRRORED_REPEAT, MIRROR_CLAMP_EXT (MIRROR_CLAMP_ATI), MIRROR_CLAMP_TO_EDGE_EXT (MIRROR_CLAMP_TO_EDGE_ATI) or MIRROR_CLAMP_TO_BORDER_EXT. The error INVALID_ENUM is generated if the target is TEXTURE_RECTANGLE_ARB and the TEXTURE_MIN_FILTER is set to a value other than NEAREST or LINEAR (no mipmap filtering is permitted). The error INVALID_ENUM is generated if the target is TEXTURE_RECTANGLE_ARB and TEXTURE_BASE_LEVEL is set to any value other than zero."

- (3.8.7, pg. 170) "Texture Wrap Modes"

Add this final additional paragraph:

"Texture coordinates are clamped differently for rectangular textures. The r texture coordinate is wrapped as described above. When the texture target is TEXTURE_RECTANGLE_ARB, the s and t coordinates are wrapped as follows: CLAMP causes the s coordinate to be clamped to the range [0, wt]. CLAMP causes the t coordinate to be clamped to the range [0, ht]. CLAMP_TO_EDGE causes the s coordinate to be clamped to the range [0.5, wt-0.5]. CLAMP_TO_EDGE causes the t coordinate to be clamped to the range [0.5, ht - 0.5]. CLAMP_TO_BORDER causes the s coordinate to be clamped to the range [-0.5, wt + 0.5]. CLAMP_TO_BORDER causes the t coordinate to be clamped to the range [-0.5, ht + 0.5]."

- (3.8.8, pg. 171) "Texture Minification"

Under the "Scale Factor and Level of Detail" sub-section, change the fourth paragraph in the subsection to read:

"Let s(x,y) be the function that associates an s texture coordinate with each set of window coordinates (x,y) that lie within a primitive; define t(x,y) and r(x,y) analogously. For non-rectangular textures, let u(x,y) = wt * s(x,y), v(x,y) = ht * t(x,y), and w(x,y) = dt * r(x,y), where wt, ht, and dt are as defined by equations 3.15, 3.16, and 3.17 with ws, hs, and ds equal to the width, height, and depth of the image array whose level is level_base. However, for rectangular textures let u(x, y) = s(x, y), v(x, y) = t(x, y), and w(x, y) = r(x, y)."

- (3.8.8, pg. 173) "Texture Minification"

```
  Update the last sentence in the first partial paragraph on the page
  to read:

  "Depending on whether the texture's target is rectangular or
  non-rectangular, this means the texel at location (i,j,k) becomes
  the texture value, with i given by

          / floor (u),    s < 1 and non-rectangular texture
          |
  i =     | wt - 1,      s == 1 and non-rectangular texture (3.19)
          |
          | floor(u)      s < wt and rectangular texture
          |
          \ wt-1         s >= wt and rectangular texture

  (Recall that if TEXTURE_WRAP_S is REPEAT, then 0 <= s < 1.)
  Similarly, j is found as

          / floor(v),     t < 1 and non-rectangular texture
          |
  j =     | ht - 1,      t == 1 and non-rectangular texture (3.20)
          |
          | floor(v)      t < ht and rectangular texture
          |
          \ ht-1         t >= ht and rectangular texture

  and k is found as

          / floor (w),    r < 1
  k =     |                                               (3.21)
          \ dt - 1,      r == 1"
```

- (3.8.8, pg. 171) "Texture Minification"

```
  Change the last sentence in the first partial paragraph on the page,
  directly after equation 3.21 to read:

  "For a two-dimensional or rectangular texture, k is irrelevant; the
  texel at location (i,j) becomes the texture value."
```

- (3.8.8, pg. 174) "Texture Minification"

```
  Change the sentence preceding equation 3.26:

  "For a two-dimensional or rectangular texture,"
```

- (3.8.8, pg. 175) "Mipmapping"

```
  Follow the paragraph on the page which ends with "...  must be
  defined, as discussed in section 3.8.10." with:

  "Rectangular textures do not support mipmapping (it is an error to
  specify a minification filter that requires mipmapping)."
```

- (3.8.11, pg. 178) "Texture State and Proxy State"

Change the first sentence of the first paragraph to say:

"The state necessary for texture can be divided into two categories. First, there are the ten sets of mipmap arrays (one each for the one-, two-, and three-dimensional texture targets, one for the rectangular texture target (though the rectangular texture target has only one mipmap level), and six for the cube map texture targets) and their number." ...

- (3.8.11, pg. 179) "Texture State and Proxy State"

Change the sixth and fifth to last sentences of the first paragraph to say:

"In the initial state, the value assigned to TEXTURE_MIN_FILTER is NEAREST_MIPMAP_LINEAR, except for rectangular textures where the initial value is LINEAR, and the value for TEXTURE_MAG_FILTER is LINEAR. s, t, and r warp modes are all set to REPEAT, except for rectangular textures where the initial value is CLAMP_TO_EDGE."

- (3.8.11, pg. 179) "Texture State and Proxy State"

Change the second paragraph of the section to say:

"In addition to the one-, two-, three-dimensional, rectangular, and the six cube map sets of image arrays, the partially instantiated one-, two-, and three-dimensional, rectangular, and one cube map sets of proxy image arrays are maintained." ...

- (3.8.11, pg. 179) "Texture State and Proxy State"

Change the third paragraph to:

"One- and two-dimensional and rectangular proxy arrays are operated on in the same way when TexImage1D is executed with target specified as PROXY_TEXTURE_1D, or TexImage2D is executed with target specified as PROXY_TEXTURE_2D or PROXY_TEXTURE_RECTANGLE_ARB."

- (3.8.11, pg. 180) "Texture State and Proxy State"

Change the second sentence of the fifth paragraph of the section to:

"Therefore PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_RECTANGLE_ARB, PROXY_TEXTURE_3D, and PROXY_TEXTURE_CUBE_MAP cannot be used as textures, and their images must never be queried using GetTexImage." ...

- (3.8.12, pg. 156) "Texture Objects"

Change the first sentence of the first paragraph to say:

"In addition to the default textures TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, and TEXTURE_CUBE_MAP, named one-dimensional, two-dimensional, rectangular, and three-dimensional texture objects and cube map texture objects can be created and operated on." ...

- **(3.8.12, pg. 180) "Texture Objects"**

  Change the second paragraph in the section to say:

  "A texture object is created by binding an unused name to TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, or TEXTURE_CUBE_MAP." ... "If the new texture object is bound to TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, or TEXTURE_CUBE_MAP, it remains a one-dimensional, two-dimensional, rectangular, three-dimensional, or cube map texture until it is deleted."

- **(3.8.12, pg. 180) "Texture Objects"**

  Change the third paragraph to say:

  "BindTexture may also be used to bind an existing texture object to either TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, or TEXTURE_CUBE_MAP."

- **(3.8.12, pg. 180) "Texture Objects"**

  Change paragraph five of the section to say:

  "In the initial state, TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, and TEXTURE_CUBE_MAP have one-dimensional, two-dimensional, rectangular, three-dimensional, and cube map state vectors associated with them respectively." ... "The initial, one-dimensional, two-dimensional, rectangular, three-dimensional, and cube map texture is therefore operated upon, queried, and applied as TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, and TEXTURE_CUBE_MAP respectively while 0 is bound to the corresponding targets."

- **(3.8.12, pg. 181) "Texture Objects"**

  Change paragraph six of the section to say:

  ... "If a texture that is currently bound to one of the targets TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, or TEXTURE_CUBE_MAP is deleted, it is as though BindTexture has been executed with the same <target> and <texture> zero." ...

- **(3.8.15 pg. 189) "Texture Application"**

  Replace the beginning sentences of the first paragraph with:

  "Texturing is enabled or disabled using the generic Enable and Disable commands, respectively, with the symbolic constants TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, or TEXTURE_CUBE_MAP to enable the one-dimensional, two-dimensional, rectangular, three-dimensional, or cube map texturing respectively. If both two- and one-dimensional textures are enabled, the two-dimensional texture is used. If the rectangular and either of the two- or one-dimensional textures is enabled, the rectangular texture is used. If the three-dimensional and any of the rectangular, two-dimensional, or one-dimensional textures is enabled, the three-dimensional texture is used. If the cube map texture and any of the three-dimensional, rectangular, two-dimensional, or one-dimensional textures is enabled, then cube map texturing is used.

- (3.11.2, pg. 195) "Texture Access" under "Shader Execution"

Replace the three bullets with the following language:

"...the results of a texture lookup are undefined if:

* The sampler used in a texture lookup function is of type sampler1D or sampler2D or sampler2DRect, and the texture object's internal format is DEPTH_COMPONENT, and the TEXTURE_COMPARE_MODE is not NONE.

* The sampler used in a texture lookup function is of type sampler1DShadow or sampler2DShadow or sampler2DRectShadow, and the texture object's internal format is DEPTH_COMPONENT, and the TEXTURE_COMPARE_MODE is NONE.

* The sampler used in a texture lookup function is of type sampler1DShadow or sampler2DShadow or sampler2DRectShadow, and the texture object's internal format is not DEPTH_COMPONENT."

Additions to Chapter 4 of the OpenGL 2.0 Specification (Per-Fragment Operations and the Framebuffer)

None

Additions to Chapter 5 of the OpenGL 2.0 Specification (Special Functions)

- (5.4, pg. 242) "Display Lists"

In the third to last paragraph of the section, add PROXY_TEXTURE_RECTANGLE_ARB to the list of PROXY_* tokens.

Additions to Chapter 6 of the OpenGL 2.0 Specification (State and State Requests)

- (6.1.3, pg. 247) "Enumerated Queries"

Change the fourth paragraph to say:

"The GetTexParameter parameter <target> may be one of TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, or TEXTURE_CUBE_MAP, indicating the currently bound one-dimensional, two-dimensional, rectangular, three-dimensional, or cube map texture object. For GetTexLevelParameter, <target> may be one of TEXTURE_1D, TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_3D, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_Z, PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_RECTANGLE_ARB, PROXY_TEXTURE_3D, or PROXY_TEXTURE_CUBE_MAP, indicating the one-dimensional texture object, two-dimensional texture object, rectangular texture object, three-dimensional texture object, or one of the six distinct 2D images making up the cube map texture object or one-dimensional, two-dimensional, rectangular, three-dimensional, or cube map proxy state vector. Note that TEXTURE_CUBE_MAP is not a valid <target> parameter for GetTexLevelParameter because it does not specify a particular cube map face."

- (6.1.4, pg. 248) "Texture Queries"

Change the first paragraph to read:

... "It is somewhat different from the other get commands; <tex> is a symbolic value indicating which texture (or texture face in the case of a cube map texture target name) is to be obtained. TEXTURE_1D indicates a one-dimensional texture, TEXTURE_2D indicates a two-dimensional texture, TEXTURE_RECTANGLE_ARB indicates a rectangular texture, TEXTURE_3D indicates a three-dimensional texture, and TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, and TEXTURE_CUBE_MAP_NEGATIVE_Z indicate the respective face of a cube map texture."

- (6.1.4, pg. 249) "Texture Queries"

Add a final sentence to the fourth paragraph of the section, immediately after ... "or DEPTH COMPONENT causes the error INVALID ENUM.":

"Calling GetTexImage with a lod not zero when the tex is TEXTURE_RECTANGLE_ARB causes the error INVALID_VALUE."

Additions to version 1.10.59 of the OpenGL Shading Language specification

A new preprocessor #define is added to the OpenGL Shading Language:

```
    #define GL_ARB_texture_rectangle 1
```

Change the second to last paragraph on page 12 (#extension directive):

The initial state of the compiler is as if the directive

```
    #extension all : disable
```

was issued, telling the compiler that all error and warning reporting must be done according to this specification, ignoring any extensions. The only execption to this rule is the GL_ARB_texture_rectangle extension. If the string "GL_ARB_texture_rectangle" is present in the EXTENSIONS string, as queried with GetString(), then the compiler will behave as if

```
    #extension GL_ARB_texture_rectangle : require
```

is present in the shader.

Add the following (previously reserved) keywords to the first part of section 3.6 on page 14:

```
sampler2DRect
sampler2DRectShadow
```

Add to section 8.7 "Texture Lookup Functions"

Syntax:

```
vec4 texture2DRect(sampler2DRect sampler, vec2 coord)
vec4 texture2DRectProj(sampler2DRect sampler, vec3 coord)
vec4 texture2DRectProj(sampler2DRect sampler, vec4 coord)
```

Description:

"Use the texture coordinate coord to do a texture lookup in the rectangle texture currently bound to sampler. For the projective ("Proj") version, the texture coordinate (coord.s, coord.t) is divided by the last component of coord. The third component of coord is ignored for the vec4 coord variant.

No "bias" parameter or "Lod" suffixed functions for rectangle textures are supported because mipmaps are not allowed for rectangular textures."

Syntax:

```
vec4 shadow2DRect(sampler2DRectShadow sampler, vec3 coord)
vec4 shadow2DRectProj(sampler2DRectShadow sampler, vec4 coord)
```

Description

"Use texture coordinate coord to do a depth comparison lookup on the rectangular depth texture bound to sampler, as described in section 3.8.14 of version 2.0 of the OpenGL specification. The 3rd component of coord (coord.p) is used as the R value. The texture bound to sampler must be a depth texture, or results are undefined. For the projective version ("Proj"), the texture coordinate (coord.s, coord.t, coord.p) is divided by the last component of coord, giving a R value of coord.p / coord.q.

No "bias" parameter or "Lod" suffixed functions for rectangle textures are supported because mipmaps are not allowed for rectangle textures."

Additions to the GLX Specification

None

GLX Protocol

None

Dependencies on OpenGL 1.4 and ARB_texture_mirrored_repeat

```
    If OpenGL 1.4 (or ARB_mirrored_repeat) is not supported, references
    to the MIRRORED_REPEAT (or MIRRORED_REPEAT_ARB) wrap mode in this
    document should be ignored.
```

Dependencies on ATI_texture_mirror_once

```
    If ATI_texture_mirror_once is not supported, references to the
    MIRROR_CLAMP_ATI and MIRROR_CLAMP_TO_EDGE_ATI wrap modes in this
    document should be ignored.
```

Dependencies on EXT_paletted_texture

```
    If EXT_paletted_texture is not supported, references to the
    COLOR_INDEX, COLOR_INDEX<n>_EXT, ColorTable, and ColorTableEXT
    should be ignored.
```

Dependencies on EXT_texture_compression_s3tc

```
    If EXT_texture_compression_s3tc is not supported, references
    to CompressedTexImage2D and CompressedTexSubImageARB and the
    COMPRESSED_*_S3TC_DXT*_EXT enumerants should be ignored.
```

Dependencies on EXT_texture_mirror_clamp

```
    If EXT_texture_mirror_clamp is not supported, references to the
    MIRROR_CLAMP_EXT, MIRROR_CLAMP_TO_EDGE_EXT, and
    MIRROR_CLAMP_TO_BORDER_EXT wrap modes in this document should be
    ignored.
```

Errors

```
    INVALID_ENUM is generated when ColorTable (or ColorTableEXT or the
    various ColorTable and ColorTableEXT alternative commands) is called
    and the target is TEXTURE_RECTANGLE_ARB or
    PROXY_TEXTURE_RECTANGLE_ARB.

    INVALID_ENUM is generated when TexImage2D is called and the target
    is TEXTURE_RECTANGLE_ARB or PROXY_TEXTURE_RECTANGLE_ARB and the
    format is COLOR_INDEX or the internalformat is COLOR_INDEX or one of
    the COLOR_INDEX<n>_EXT internal formats.

    INVALID_VALUE is generated when TexImage2D is called when the target
    is TEXTURE_RECTANGLE_ARB if border is any value other than zero or
    the level is any value other than zero.

    INVALID_VALUE is generated when TexImage2D is called when the target
    is TEXTURE_RECTANGLE_ARB if the width is less than zero or the
    height is less than zero.

    INVALID_VALUE is generated when TexSubImage2D or CopyTexSubImage2D
    is called when the target is TEXTURE_RECTANGLE_ARB if the level is
    any value other than zero.

    INVALID_ENUM is generated when one of the CompressedTexImage<n>D
    commands is called when the target parameter is
```

    TEXTURE_RECTANGLE_ARB or PROXY_TEXTURE_RECTANGLE_ARB.

    INVALID_ENUM is generated when one of the CompressedTexSubImage<n>D
    commands is called when the target parameter is TEXTURE_RECTANGLE_ARB
    or PROXY_TEXTURE_RECTANGLE_ARB.

    INVALID_ENUM is generated when TexParameter is called with a target
    of TEXTURE_RECTANGLE_ARB and the TEXTURE_WRAP_S, TEXTURE_WRAP_T,
    or TEXTURE_WRAP_R parameter is set to REPEAT, MIRRORED_REPEAT,
    MIRROR_CLAMP_ATI, or MIRROR_CLAMP_TO_EDGE_ATI.

    INVALID_ENUM is generated when TexParameter is called with a target
    of TEXTURE_RECTANGLE_ARB and the TEXTURE_MIN_FILTER is set to a
    value other than NEAREST or LINEAR.

    INVALID_VALUE is generated when TexParameter is called with a target
    of TEXTURE_RECTANGLE_ARB and the TEXTURE_BASE_LEVEL is set to any
    value other than zero.

    INVALID_VALUE is generated when GetTexImage is called with a lod not
    zero when the tex is TEXTURE_RECTANGLE_ARB.

New State

  - (Table 6.15, Texture Objects, pg. 241) amend/add the following entries:

Get Value	Type	Get Command	Initial Value	Description	Sec	Attribute
TEXTURE_RECTANGLE_ARB	2* x B	IsEnabled	False	True if rectangular texturing is enabled	3.8.15	texture/enable
TEXTURE_BINDING_RECTANGLE_ARB	2* x Z+	GetIntegerv	0	Texture object for texture rectangle	3.8.11	texture
TEXTURE_RECTANGLE_ARB	n x I	GetTexImage	see 3.8	rectangular texture image for lod 0	3.8	-

  - (Table 6.16, Texture Objects (cont.), pg. 242) amend/add the following
entries:

Get Value	Type	Get Command	Initial Value	Description	Sec	Attribute
TEXTURE_MIN_FILTER	n x Z6	GetTexParameter	See 3.8 except for rectangular which is LINEAR	Texture minification function	3.8.8	texture
TEXTURE_WRAP_S	n x Z5	GetTexParameter	REPEAT except for rectangular which is CLAMP_TO_EDGE	Texture wrap mode S	3.8.7	texture
TEXTURE_WRAP_T	n x Z5	GetTexParameter	REPEAT except for rectangular which is CLAMP_TO_EDGE	Texture wrap mode T (2D, 3D, cubemap, rectangle textures only)	3.8.7	texture
TEXTURE_WRAP_R	n x Z5	GetTexParameter	REPEAT except for rectangular which is CLAMP_TO_EDGE	Texture wrap mode R (3D textures only)	3.8.7	texture

New Implementation Dependent State

  - (Table 6.28, Implementation Dependent Values, pg. 254) add the following entry:

Get Value	Type	Get Command	Minimum Value	Description	Sec	Attribute
MAX_RECTANGLE_TEXTURE_SIZE_ARB	Z+	GetIntegerv	64	Maximum rectangular texture image dimension	3.8.1	-

Backwards Compatibility

This extension is semantically equivalent to EXT_texture_rectangle and NV_texture_rectangle. The tokens, and name strings now refer to ARB instead of EXT or NV. Enumerant values are unchanged.

Revision History

3/5/2004 - Updated page numbers and other numbers to reflect OpenGL 1.5; removed bogus "Convolution" language saying how glGetTexImage applies convolution (language was in 1.2.1 but removed in 1.3). ARB_texture_non_power_of_two and EXT_texture_mirror_clamp interactions added.

2/23/2005 - Fix the GLSL interaction: 1) GLSL functions require a vector (not scalar) parameter for the texture coordinate set: 2) The actual reserved types are sampler2DRect and sampler2DRectShadow (not samplerRect and samplerRectShadow); and 3) the shadow functions were missing.

7/8/2005 - Further fixes to GLSL interaction based on ARB meeting discussion: 1) Add OpenGL 2.0 language interaction for when shadow accesses are defined for rectangle textures; 2) add an issue to document the discussion; 3) bumped revision to 1.1; 4) documented GLSL preprocessor define; 5) documented sampler enums; and generally update the specification page numbers to be written against OpenGL 2.0. Also added to the contributors list.

7/15/2005 - This is revision 1.2.
1) Allow loading of DEPTH_COMPENENT textures for rectangular texture targets. 2) Switched some of the paramters ws, hs, ds for wt, ht, dt, and vice-versa to be in line with the cleanup already done in the OpenGL 2.0 specification. 3) Added issue 18. 4) Deleted the 'dependencies on ARB_texture_non_power_of_two' section since that is core OpenGL 2.0 functionality. 5) Removed some redundant language. 6) Added language describing changes to the GLSL spec explaining the #extension behavior. 7) Added to the contributors list and sorted it by last name.

10/4/2005 - Revision 1.21 - Whitespace cleanup

Name

    ARB_transpose_matrix

Name Strings

    GL_ARB_transpose_matrix

Status

    Complete. Approved by ARB on 12/8/1999

Version

    Last Modified Date: January 3, 2000
    Author Revision: 1.3

Number

    ARB Extension #3

Dependencies

    This extensions is written against the OpenGL 1.2 Specification.
    May be implemented in any version of OpenGL.

Overview

    New functions and tokens are added allowing application matrices
    stored in row major order rather than column major order to be
    transferred to the OpenGL implementation. This allows an application
    to use standard C-language 2-dimensional arrays (m[row][col]) and
    have the array indices match the expected matrix row and column indexes.
    These arrays are referred to as transpose matrices since they are
    the transpose of the standard matrices passed to OpenGL.

    This extension adds an interface for transfering data to and from the
    OpenGL pipeline, it does not change any OpenGL processing or imply any
    changes in state representation.

IP Status

    No IP is believed to be involved.

Issues

    * Why do this?

        It's very useful for layered libraries that desire to use two
        dimensional C arrays as matrices. It avoids having the layered
        library perform the transpose itself before calling OpenGL since
        most OpenGL implementations can efficiently perform the transpose
        while reading the matrix from client memory.

    * Why not add a mode?

        It's substantially more confusing and complicated to add a mode.

```
        Simply adding two new entry points saves considerable confusion
        and avoids having layered libraries need to query the current mode
        in order to send a matrix with the correct memory layout.

    * Why not a utility routine in GLU

        It costs some performance.  It is believed that most OpenGL
        implementations can perform the transpose in place with negligble
        performance penalty.

    * Why use the name transpose?

        It's sure a lot less confusing than trying to ascribe unambiguous
        meaning to terms like row and column.  It could be matrix_transpose
        rather than transpose_matrix though.

    * Short Transpose to Trans?
```

New Procedures and Functions

```
    void LoadTransposeMatrix{fd}ARB(T m[16]);
    void MultTransposeMatrix{fd}ARB(T m[16]);
```

New Tokens

```
    Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv,
    and GetDoublev

        TRANSPOSE_MODELVIEW_MATRIX_ARB    0x84E3
        TRANSPOSE_PROJECTION_MATRIX_ARB   0x84E4
        TRANSPOSE_TEXTURE_MATRIX_ARB      0x84E5
        TRANSPOSE_COLOR_MATRIX_ARB        0x84E6
```

Additions to Chapter 2 of the 1.2 OpenGL Specification (OpenGL Operation)

```
    Add to Section 2.10.2 Matrices  <before LoadIdentity>

    LoadTransposeMatrixARB takes a 4x4 matrix stored in row-major order as
    Let transpose(m,n) be defined as

        n[0] = m[0];
        n[1] = m[4];
        n[2] = m[8];
        n[3] = m[12];
        n[4] = m[1];
        n[5] = m[5];
        n[6] = m[9];
        n[7] = m[13];
        n[8] = m[2];
        n[9] = m[6];
        n[10] = m[10];
        n[11] = m[14];
        n[12] = m[3];
        n[13] = m[7];
        n[14] = m[11];
        n[15] = m[15];

    The effect of LoadTransposeMatrixARB(m) is then the same as the effect of
    the command sequence

        float n[16];
        transpose(m,n)
        LoadMatrix(n);

    The effect of MultTransposeMatrixARB(m) is then the same as the effect of
    the command sequence

        float n[16];
        transpose(m,n);
        MultMatrix(n);
```

Additions to Chapter 3 of the 1.2 OpenGL Specification (Rasterization)

```
    None
```

Additions to Chapter 4 of the 1.2 OpenGL Specification (Per-Fragment Operations and the Framebuffer)

```
    None
```

Additions to Chapter 5 of the 1.2 OpenGL Specification (Special Functions)

```
    None
```

Additions to Chapter 6 of the 1.2 OpenGL Specification (State and State Requests)

```
    Matrices are queried and returned in their transposed form by calling
    GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev with <pname> set to
    TRANSPOSE_MODELVIEW_MATRIX_ARB, TRANSPOSE_PROJECTION_MATRIX_ARB,
    TRANSPOSE_TEXTURE_MATRIX_ARB, or TRANSPOSE_COLOR_MATRIX_ARB.
    The effect of GetFloatv(TRANSPOSE_MODELVIEW_MATRIX_ARB,m) is then the same
    as the effect of the command sequence
```

```
        float n[16];
        GetFloatv(MODELVIEW_MATRIX_ARB,n);
        transpose(n,m);
```

    Similar results occur for TRANSPOSE_PROJECTION_MATRIX_ARB,
    TRANSPOSE_TEXTURE_MATRIX_ARB, and TRANSPOSE_COLOR_MATRIX_ARB.

Additions to Appendix A of the OpenGL 1.2.1 Specification (Invariance)

None

Additions to the GLX Specification

None

GLX Protocol

LoadTransposeMatrix and MultTransposeMatrix are layered on top of LoadMatrix and MultMatrix protocol performing client-side translation. The Get commands are passed over the wire as part of the generic Get protocol with no translation required.

Errors

No new errors, but error behavoir is inherited by the commands that the transpose commands are implemented on top of (LoadMatrix, MultMatrix, and Get*).

New State

None

TRANSPOSE_*_MATRIX_ARB refer to the same state as their non-transposed counterparts.

New Implementation Dependent State

None

Revision History

```
    * Revision 1.1 - initial draft (18 Mar 1999)
    * Revision 1.2 - changed to use layered specification and ARB affix
                     (23 Nov 1999)
    * Revision 1.3 - Minor tweaks to GLX protocol and Errors. (7 Dec 1999)
```

Conformance Testing

Load and Multiply the modelview matrix (initialized to identity each time) using LoadTransposeMatrixfARB and MultTransposeMatrixfARB with the matrix:

```
        ( 1  2  3  4 )
        ( 5  6  7  8 )
        ( 9 10 11 12 )
        (13 14 15 16 )

    and get the modelview matrix using TRANSPOSE_MODELVIEW_MATRIX_ARB and
    validate that the matrix is correct.  Get the matrix using
    MODELVIEW_MATRIX and verify that it is the transpose of the above
    matrix.  Load and Multiply the modelview matrix using LoadMatrixf
    and MultMatrixf with the above matrix and verify that the correct
    matrix is on the modelview stack using gets of MODELVIEW_MATRIX
    and TRANSPOSE_MODELVIEW_MATRIX_ARB.
```

Name

Number

    ARB Extension #28

Dependencies

    Written based on the wording of the OpenGL 1.4 specification.

    GL_ARB_vertex_blend affects the definition of this extension.

    GL_ARB_vertex_program affects the definition of this extension.

    GL_EXT_vertex_shader affects the definition of this extension.

Overview

    This extension defines an interface that allows various types of data
    (especially vertex array data) to be cached in high-performance
    graphics memory on the server, thereby increasing the rate of data
    transfers.

    Chunks of data are encapsulated within "buffer objects", which
    conceptually are nothing more than arrays of bytes, just like any
    chunk of memory. An API is provided whereby applications can read
    from or write to buffers, either via the GL itself (glBufferData,
    glBufferSubData, glGetBufferSubData) or via a pointer to the memory.

    The latter technique is known as "mapping" a buffer. When an
    application maps a buffer, it is given a pointer to the memory. When
    the application finishes reading from or writing to the memory, it is
    required to "unmap" the buffer before it is once again permitted to
    use that buffer as a GL data source or sink. Mapping often allows
    applications to eliminate an extra data copy otherwise required to
    access the buffer, thereby enhancing performance. In addition,
    requiring that applications unmap the buffer to use it as a data
    source or sink ensures that certain classes of latent synchronization

bugs cannot occur.

Although this extension only defines hooks for buffer objects to be used with OpenGL's vertex array APIs, the API defined in this extension permits buffer objects to be used as either data sources or sinks for any GL command that takes a pointer as an argument. Normally, in the absence of this extension, a pointer passed into the GL is simply a pointer to the user's data. This extension defines a mechanism whereby this pointer is used not as a pointer to the data itself, but as an offset into a currently bound buffer object. The buffer object ID zero is reserved, and when buffer object zero is bound to a given target, the commands affected by that buffer binding behave normally. When a nonzero buffer ID is bound, then the pointer represents an offset.

In the case of vertex arrays, this extension defines not merely one binding for all attributes, but a separate binding for each individual attribute. As a result, applications can source their attributes from multiple buffers. An application might, for example, have a model with constant texture coordinates and variable geometry. The texture coordinates might be retrieved from a buffer object with the usage mode "STATIC_DRAW", indicating to the GL that the application does not expect to update the contents of the buffer frequently or even at all, while the vertices might be retrieved from a buffer object with the usage mode "STREAM_DRAW", indicating that the vertices will be updated on a regular basis.

In addition, a binding is defined by which applications can source index data (as used by DrawElements, DrawRangeElements, and MultiDrawElements) from a buffer object. On some platforms, this enables very large models to be rendered with no more than a few small commands to the graphics device.

It is expected that a future extension will allow sourcing pixel data from and writing pixel data to a buffer object.

Issues

What should this extension be called?

RESOLVED: By unanimous consent among the working group members, the name was chosen to be "ARB_vertex_buffer_object". A large number of other names were considered throughout the lifetime of the proposal, especially "vertex_array_object" (originally), "buffer_object" (later on), and "memory_object" (near the end), but the name "vertex_buffer_object" was ultimately chosen.

In particular, this name emphasizes not only that we have created a new type of object that encapsulates arbitrary data (buffer objects), but also, in particular, that these objects are used in this extension to source vertex data. The name also is intentionally similar to "vertex buffers", although it should be emphasized that there is no such thing as a "vertex buffer" in the terminology of this extension. The term "buffer object" is the correct noun.

How is this extension different from ATI_vertex_array_object plus ATI_map_object_buffer?

The following summarizes the major differences.
- VAOs renamed to "buffer objects", to signify that they can be used for more than just vertex data. Other renaming and API changes to try to better match OpenGL conventions.
- The standard GL pointer APIs have been overloaded to be able to refer to offsets within these buffers, rather than adding new entry points.
- The usage modes permitted for buffers have been augmented significantly, to reflect a broader class of application behaviors.
- A new entry point allows reading back the contents of a buffer object.

How is this extension different from NV_vertex_array_range?

The following summarizes the major differences.
- Applications are no longer responsible for memory management and synchronization.
- Applications may still access high-performance memory, but this is optional, and such access is more restricted.
- Buffer changes (glBindBufferARB) are generally expected to be very lightweight, rather than extremely heavyweight (glVertexArrayRangeNV).
- A platform-specific allocator such as wgl/glXAllocateMemoryNV is no longer required.

How does this extension relate to NV_pixel_data_range?

A future extension could be created based on the framework created here that would support analogous functionality to that provided by NV_pixel_data_range. Presumably, this extension would require little more than two new targets for BindBuffer, named (say) UNPACK_PIXELS and PACK_PIXELS. The lists of commands affected by these bindings could easily be taken verbatim out of the NV_pixel_data_range specification.

Should this extension include support for allowing vertex indices to be stored in buffer objects?

RESOLVED: YES. It is easily and cleanly added with just the addition of a binding point for the index buffer object. Since our approach of overloading pointers works for any pointer in GL, no additional APIs need be defined, unlike in the various *_element_array extensions.

Note that it is expected that implementations may have different memory type requirements for efficient storage of indices and vertices. For example, some systems may prefer indices in AGP memory and vertices in video memory, or vice versa; or, on systems where DMA of index data is not supported, index data must be stored in (cacheable) system memory for acceptable performance. As a result, applications are strongly urged to put their models' vertex and index data in separate buffers, to assist drivers in choosing the most efficient locations.

Should the layout of an array store be defined at array store creation time?

RESOLVED: NO. This could provide better performance if the client specifies a data type that the hardware doesn't support, but this isn't a performance path anyways, and it adds a cumbersome interface on top of the extension.

Should there be some sort of scheme for allowing applications to stream vertex data efficiently?

RESOLVED: YES. Applications that generate their data on the fly end up doing an extra data copy unless they are given a pointer into memory that the graphics hardware can DMA from. The performance win from doing this can be significant.

Should the client be able to retrieve a pointer to a buffer object?

RESOLVED: YES. This solves the previous problem. Since GL vertex array formats are already user-visible, this does not suffer from the sorts of formatting issues that would arise if the GL allowed applications to retrieve pointers to texture objects or to the framebuffer. Synchronization can be a concern, but proper usage of this extension will minimize its overhead.

Should this extension sit on top of the existing vertex array implementation, instead of introducing a new set of API calls?

RESOLVED: YES. This simplifies the API, and separating out the buffer binding from the offset/stride within the buffer leads to an elegant "BindBufferARB" command that can be used for other parts of GL like the pixel path.

Should buffer object state overlap with existing vertex array pointer state, or should there be new drawing commands, e.g., DrawArrayObject?

RESOLVED: OVERLAP. The exponential growth in drawing commands is problematic. Even without this, there is already ArrayElement, DrawArrays, DrawElements, DrawRangeElements, MultiDrawArrays, and MultiDrawElements.

Does the buffer binding state push/pop?

RESOLVED: YES. It pushes/pops on the client with the rest of the vertex array state. Some revisions of the ATI VAO spec listed a push/pop attrib "objbuf", but no new bit was defined; all this has been moved into the standard "vertex-array" bit.

Note that both the user-controlled binding ARRAY_BUFFER_ARB binding point and the per-array bindings push and pop.

Note that additional binding points, such as ones for pixel or texture transfers, would not be part of the vertex array state, and thus would likely push and pop as part of the pixel store (client) state when they are defined.

How is the decision whether to use the array pointer as an offset or as a real pointer made?

RESOLVED: When the default buffer object (object zero) is bound, all pointers behave as real pointers. When any other object is bound, all pointers are treated as offsets. Conceptually, one can imagine that buffer object zero is a buffer object sitting at base NULL and with an extent large enough that it covers all of the system's virtual address space.

Note that this approach essentially requires that binding points be client (not server) state.

Can buffer objects be shared between contexts in the same way that display lists are?

RESOLVED: YES. All potentially large OpenGL objects, such as display lists and textures, can be shared, and this is an important capability. Note, however, that sharing requires that buffer objects be server (not client) state, since it is not possible to share client state.

Should buffer objects be client state or server state?

RESOLVED: Server state. Arguments for client state include:

- Buffer data are stored in client-side format, making server storage complex when client and server endianness differ.
- Vertex arrays are client state.

These arguments are outweighed by the significant advantages of server state, including:

- Server state can be shared between contexts, and this is expected to be an important capability (sharing of texture objects is very common).
- In the case of indirect rendering, performance may be very significantly greater for data stored on the server side of the wire.

How is synchronization enforced when buffer objects are shared by multiple OpenGL contexts?

RESOLVED: It is generally the clients' responsibility to synchronize modifications made to shared buffer objects. GL implementations will make some effort to avoid deletion of in-use buffer objects, but may not be able to ensure this handling.

What happens if a currently bound buffer object is deleted?

RESOLVED: Orphan. To avoid chasing invalid pointers OpenGL implementations will attempt to defer the deletion of any buffer object until that object is not bound by any client in the share list. It should be possible to implement this behavior efficiently in the direct rendering case, but the implementation may be difficult/impossible in the indirect rendering case.

Since synchronization during sharing is a client responsibility, this behavior is acceptable.

Should there be a way to query the data in a buffer object?

RESOLVED: YES. Almost all objects in OpenGL are fully queriable, and since these objects are simply byte arrays, there does not seem to be any reason to do things otherwise here. The primary exceptions to GL queriability are cases where such functionality would be extremely burdensome to provide, as is the case with display lists.

Do buffer objects survive screen resolution changes, etc.?

RESOLVED: YES. This is not mentioned in the spec, so by default they behave just like other OpenGL state, like texture objects -- the data is unmodified by external events like modeswitches, switching the system into standby or hibernate mode, etc.

What happens to a mapped buffer when a screen resolution change or other such window-system-specific system event occurs?

RESOLVED: The buffer's contents may become undefined. The application will then be notified at Unmap time that the buffer's contents have been destroyed. However, for the remaining duration of the map, the pointer returned from Map must continue to point to valid memory, in order to ensure that the application cannot crash if it continues to read or write after the system event has been handled.

What happens to the pointer returned by MapBufferARB after a call to UnmapBufferARB?

RESOLVED: The pointer becomes totally invalid. Note that drivers are free to move the underlying buffer or even unmap the memory, leaving the virtual addresses in question pointing at nothing. Such flexibility is necessary to enable efficient implementations on systems with no virtual memory; with limited control over virtual memory from graphics drivers; or where virtual address space is at a premium.

How does indirect rendering work?

It is not currently specified, but the basic planned outline is as follows.

All of the object management commands -- Gen, Is, Delete -- go to the server immediately with normal protocol. So does Bind. However, when someone does an implicit bind via one of the pointer commands (e.g. VertexPointer), the server may not necessarily be notified immediately of the new object bound to the (in this case) VERTEX_ARRAY_BUFFER_BINDING.

BufferData and BufferSubData are sent over the wire just as TexImage2D and TexSubImage2D, and GetBufferSubData does a round trip, just like GetTexImage. MapBuffer goes over the wire with a request to map; the server replies to tell the client whether the map succeeded or failed, and the client returns a pointer to a system memory buffer in the event of success. If the map is readable, the server passes back the contents of the buffer, while if the map is writeable, at Unmap time, the client passes back the new contents. Unmap would always return TRUE.

Both GetBufferParameteriv and GetBufferPointerv go to the server.

Whenever the application sources data from a buffer object, several new protocols are defined to specify where to obtain the data from. One new command might be called "BindArray", which would have arguments <array>, <buffer>, offset>, <type>, <size>, <stride>, and <normalized>. <array> might be VERTEX_ARRAY, NORMAL_ARRAY, etc. <buffer> would be the ID of the buffer object to be used as source, or zero if no buffer object. <offset> would be a 64-bit (?) integer. <type>, <size>, <stride>, and <normalized> would all be the same as the various arguments to the *Pointer commands. Another new command might be "ArrayElementServer", which would dereference all arrays with a nonzero <buffer> on the server side, just as if immediate mode had been used. If only some arrays were coming from buffer objects and some from user memory, the client would dereference the ones in user memory and pass them in as immediate mode protocol.

If all arrays came from the server, additional optimized APIs could be provided. A "DrawArraysServer" and "DrawElementsServer" would be cheaper than a sequence of "ArrayElementServer" commands. For indices coming from a buffer object, a "DrawElementArrayServer" might be added.

At initialization time, the client and server would exchange a handshake to see if the server can understand the client's storage of the various GL data types. It is expected that nearly all clients and servers would use just two data type representations, namely, "standard little endian with IEEE floats" and "standard big endian with IEEE floats".

Are any of these commands allowed inside Begin/End?

RESOLVED: NO, with the possible exception of BindBuffer, which should not be used inside a Begin/End but will have undefined error behavior, like most vertex array commands.

What happens when an attempt is made to access data outside the bounds of the buffer object with a command that dereferences the arrays?

RESOLVED: ALLOW PROGRAM TERMINATION. In the event of a software fallback, bounds checking can become impractical. Since applications don't know the actual address of the buffer object and only provide an offset, they can't ever guarantee that out-of-bounds offsets will fall on valid memory. So it's hard to do any better than this.

Of course, such an event should not be able to bring down the system, only terminate the program.

What type should <offset> and <size> arguments use?

RESOLVED: We define new types that will work well on 64-bit systems, analogous to C's "intptr_t". The new type "GLintptrARB" should be used in place of GLint whenever it is expected that values might exceed 2 billion. The new type "GLsizeiptrARB" should be used in place of GLsizei whenever it is expected that counts might exceed 2 billion. Both types are defined as signed integers large enough to contain any pointer value. As a result, they naturally scale to larger numbers of bits on systems with 64-bit or even larger pointers.

The offsets introduced in this extension are typed GLintptrARB, consistent with other GL parameters that must be non-negative, but are arithmetic in nature (not uint), and are not sizes; for example, the xoffset argument to TexSubImage*D is of type GLint. Buffer sizes are typed GLsizeiptrARB.

The idea of making these types unsigned was considered, but was ultimately rejected on the grounds that supporting buffers larger than 2 GB was not deemed important on 32-bit systems.

Should buffer maps be client or server state?

RESOLVED: Server. If a buffer is being shared by multiple clients, it will also be desirable to share the mappings of that buffer. In cases where the mapping cannot shared (for example, in the case of indirect rendering) queries of the map pointer by clients other than the one that created the map will return a null pointer.

Should "Unmap" be treated as one word or two?

RESOLVED: One word.

Should "usage" be a parameter to BufferDataARB, or specified separately using a parameter specification command, e.g., BufferParameteriARB?

RESOLVED: Parameter to BufferDataARB. It is desirable for the implementation to know the usage when the buffer is initialized, so including it in the initialization command makes sense. This avoids manpage notes such as "Please specify the usage before you initialize the buffer".

Should it be possible to change the usage of an initialized buffer?

RESOLVED: NO. Unless it is shown that this flexibility is necessary, it will be easier for implementations to be efficient if usage cannot be changed. (Except by re-initializing the buffer completely.)

Should we allow for the possibility of multiple simultaneous maps for a single buffer?

RESOLVED: NO. If multiple maps are allowed, the mapping semantics become very difficult to understand and to specify. It is also unclear that there are any benefits to offering such functionality. Therefore, only one map per buffer is permitted.

Note: the limit of one map per buffer eliminates any need for "sub-region" mapping. The single map always maps the entire data store of the buffer.

Should it be an error to render from a currently mapped buffer?

RESOLVED: YES. Making this an error rather than undefined makes the API much more bulletproof.

Should it be possible for the application to query the "viability" of the data store of a buffer?

RESOLVED: NO. UnmapBuffer can return FALSE to indicate this, but there is no additional query to check whether the data has been lost. In general, most/all GL state is queriable, unless there is a compelling reason otherwise. However, on examination, it appears that there are several compelling reasons otherwise in this case. In particular, the default for this state variable is non-obvious (is the data "valid" when no data has been specified yet?), and it's unclear when it should be reset (BufferData only? BufferSubData? A successful UnmapBuffer?). After these issues came to light, the query was removed from the spec.

What should the error behavior of BufferDataARB and MapBufferARB be?

RESOLVED: BufferDataARB returns no value and sets OUT_OF_MEMORY if the buffer could not be created, whereas MapBufferARB returns NULL and also sets OUT_OF_MEMORY if the buffer could not be mapped.

Should UnmapBufferARB return a boolean indicating data integrity?

RESOLVED: YES, since the Unmap is precisely the point at which the buffer can no longer be lost.

How is unaligned data handled?

RESOLVED: All client restrictions on data alignment must be met, and in addition to that, all offsets must be multiples of the size of the underlying data type. So, for example, float data in a buffer object must have an offset that is (typically) a multiple of 4. This should make the server implementation easier, since this additional rule will guarantee that no alignment checking is required on most platforms.

Should MapBufferARB return the pointer to the map, or should there be a separate call to ask for the pointer?

RESOLVED: BOTH. For convenience, MapBufferARB returns a pointer or NULL in the event of failure; but since most/all GL state is queriable, you can also query the pointer at a later point in time. If the buffer is not mapped, querying the pointer should return NULL.

Should there be one binding point for all arrays or several binding points, one for each array?

RESOLVED: One binding point for all arrays. Index data uses a separate target.

Should there be a PRESERVE/DISCARD option on BufferSubDataARB? On MapBufferARB?

RESOLVED: NO, NO. ATI_vertex_array_object had this option for UpdateObjectBufferATI, which is the equivalent of BufferSubDataARB, but it's unclear whether this has any utility. There might be some utility for MapBufferARB, but forcing the user to call BufferDataARB again with a NULL data pointer has some advantages of its own, such as forcing the user to respecify the size.

Should there be an option for MapBufferARB that guarantees nonvolatile memory?

RESOLVED: NO. On systems where volatile memory spaces are a concern, there is little or no way to supply nonvolatile memory without crippling performance badly. In some cases, it might not even be possible to implement Map except by returning system memory. Systems that do not have problems with volatility are, of course, welcome to return TRUE from UnmapBufferARB all the time. If applications want the ease of use that results from not having to check for lost data, they can still use BufferDataARB and BufferSubDataARB, so the burden is not too great.

What new usages do we need to add?

RESOLVED. We have defined a 3x3 matrix of usages. The pixel-related terms draw, read, and copy are used to distinguish between three basic data paths: application to GL (draw), GL to application (read), and GL to GL (copy). The terms stream, static, and dynamic are used to identify three data access patterns: specify once and use once or perhaps only a few times (stream), specify once and use many times (static), and specify and use repeatedly (dynamic).

Note that the "copy" and "read" usage token values will become meaningful only when pixel transfer capability is added to buffer objects by a (presumed) subsequent extension.

Note that the data paths "draw", "read", and "copy" are analogous in both name and meaning to the GL commands DrawPixels, ReadPixels, and CopyPixels, respectively.

Is it legal C to use pointers as offsets?

We haven't come to any definitive conclusion about this. The proposal is to convert to pointer as:

```
pointer = (char *)NULL + offset;
```

And convert back to offset as:

```
offset = (char *)pointer - (char *)NULL;
```

Varying opinions have been expressed as to whether this is legal, although no one could provide an example of a real system where any problems would occur.

Should we add new Offset commands, e.g., VertexOffset, if the pointer approach has some compatibility concerns?

RESOLVED: NO. The working group voted that the existing pointer-as-offset approach is acceptable.

Which commands are compiled into display lists?

RESOLVED: None of the commands in this extension are compiled into display lists. The reasoning is that the server may not have up-to-date buffer bindings, since BindBuffer is a client command.

Just as without this extension, vertex data is dereferenced when ArrayElement, etc. are compiled into a display list.

Should there be a new command "DiscardAndMapBuffer" that is equivalent to BufferDataARB with NULL pointer followed by MapBufferARB?

RESOLVED: NO, no one has come up with a clearly superior proposal that everyone can agree on.

Are any GL commands disallowed when at least one buffer object is mapped?

RESOLVED: NO. In general, applications may use whatever GL commands they wish when a buffer is mapped. However, several other restrictions on the application do apply: the application must not attempt to source data out of, or sink data into, a currently mapped buffer. Furthermore, the application may not use the pointer returned by Map as an argument to a GL command. (Note that this last restriction is unlikely to be enforced in practice, but it violates reasonable expectations about how the extension should be used, and it doesn't seem to be a very interesting usage model anyhow. Maps are for the user, not for the GL.)

More restrictive rules were considered (for example, "after calling MapBuffer, all GL commands except for UnmapBuffer produce errors"), but this was considered far too restrictive. The expectation is that an application might map a buffer and start filling it in a different thread, but continue to render in its main thread (using a different buffer or no buffer at all). So no commands are disallowed simply because a buffer happens to be mapped.

Should the usage and data arguments to BufferDataARB be swapped?

RESOLVED: NO. This would be more consistent with other things in GL if they were swapped, but no one seems to care. If we had caught this earlier, maybe, but it's just too late.

How does MultiDrawElements work?

The language gets a little confusing, but I believe it is quite clearly specified in the end. The argument <indices> to MultiDrawElements, which is of type "const void **", is an honest-to-goodness pointer to regular old system memory, no matter whether a buffer is bound or not. That memory in turn consists of an array of <primcount> pointers. If no buffer is bound, each of those <primcount> pointers is a regular pointer. If a buffer is bound, each of those <primcount> pointers is a fake pointer that represents an offset in the buffer object.

If you wanted to put the array of <primcount> offsets in a buffer object, you'd have to define a new extension with a new target.

When is the binding between a buffer object and a specific vertex array (e.g., VERTEX_ARRAY_BUFFER_BINDING_ARB) established?

The array's buffer binding is set when the array pointer is specified. Using the vertex array as an example, this is when VertexPointer is called. At that time, the current array buffer binding is used for the vertex array. The current array buffer binding is set by calling BindBufferARB with a <target> of ARRAY_BUFFER_ARB. Changing the current array buffer binding does not affect the bindings used by already established arrays.

```
  BindBufferARB(ARRAY_BUFFER_ARB, 1);
  VertexPointer(...);   // vertex array data points to buffer 1
  BindBufferARB(ARRAY_BUFFER_ARB, 2);
  // vertex array data still points to buffer 1
```

New Procedures and Functions

```
    void BindBufferARB(enum target, uint buffer);
    void DeleteBuffersARB(sizei n, const uint *buffers);
    void GenBuffersARB(sizei n, uint *buffers);
    boolean IsBufferARB(uint buffer);

    void BufferDataARB(enum target, sizeiptrARB size, const void *data,
                       enum usage);
    void BufferSubDataARB(enum target, intptrARB offset, sizeiptrARB size,
                          const void *data);
    void GetBufferSubDataARB(enum target, intptrARB offset,
                             sizeiptrARB size, void *data);

    void *MapBufferARB(enum target, enum access);
    boolean UnmapBufferARB(enum target);

    void GetBufferParameterivARB(enum target, enum pname, int *params);
    void GetBufferPointervARB(enum target, enum pname, void **params);
```

New Tokens

Accepted by the <target> parameters of BindBufferARB, BufferDataARB, BufferSubDataARB, MapBufferARB, UnmapBufferARB, GetBufferSubDataARB, GetBufferParameterivARB, and GetBufferPointervARB:

```
        ARRAY_BUFFER_ARB                                0x8892
        ELEMENT_ARRAY_BUFFER_ARB                        0x8893
```

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
        ARRAY_BUFFER_BINDING_ARB                        0x8894
        ELEMENT_ARRAY_BUFFER_BINDING_ARB                0x8895
        VERTEX_ARRAY_BUFFER_BINDING_ARB                 0x8896
        NORMAL_ARRAY_BUFFER_BINDING_ARB                 0x8897
        COLOR_ARRAY_BUFFER_BINDING_ARB                  0x8898
        INDEX_ARRAY_BUFFER_BINDING_ARB                  0x8899
        TEXTURE_COORD_ARRAY_BUFFER_BINDING_ARB          0x889A
        EDGE_FLAG_ARRAY_BUFFER_BINDING_ARB              0x889B
        SECONDARY_COLOR_ARRAY_BUFFER_BINDING_ARB        0x889C
        FOG_COORDINATE_ARRAY_BUFFER_BINDING_ARB         0x889D
        WEIGHT_ARRAY_BUFFER_BINDING_ARB                 0x889E
```

Accepted by the <pname> parameter of GetVertexAttribivARB:

```
        VERTEX_ATTRIB_ARRAY_BUFFER_BINDING_ARB          0x889F
```

Accepted by the <usage> parameter of BufferDataARB:

STREAM_DRAW_ARB	0x88E0
STREAM_READ_ARB	0x88E1
STREAM_COPY_ARB	0x88E2
STATIC_DRAW_ARB	0x88E4
STATIC_READ_ARB	0x88E5
STATIC_COPY_ARB	0x88E6
DYNAMIC_DRAW_ARB	0x88E8
DYNAMIC_READ_ARB	0x88E9
DYNAMIC_COPY_ARB	0x88EA

Accepted by the <access> parameter of MapBufferARB:

READ_ONLY_ARB	0x88B8
WRITE_ONLY_ARB	0x88B9
READ_WRITE_ARB	0x88BA

Accepted by the <pname> parameter of GetBufferParameterivARB:

BUFFER_SIZE_ARB	0x8764
BUFFER_USAGE_ARB	0x8765
BUFFER_ACCESS_ARB	0x88BB
BUFFER_MAPPED_ARB	0x88BC

Accepted by the <pname> parameter of GetBufferPointervARB:

BUFFER_MAP_POINTER_ARB	0x88BD

Additions to Chapter 2 of the 1.4 Specification (OpenGL Operation)

Add to Table 2.2:

"GL Type	Minimum Bit Width	Description
intptrARB	<ptrbits>	signed 2's complement binary integer
sizeiptrARB	<ptrbits>	Non-negative binary integer size"

Add to the paragraph under Table 2.2:

"<ptrbits> is the number of bits required to represent a pointer type; in other words, types intptrARB and sizeiptrARB must be sufficiently large as to store any address."

Add a new section "Buffer Objects" between sections 2.8 and 2.9:

"2.8A Buffer Objects

The vertex data arrays described in section 2.8 are stored in client memory. It is sometimes desirable to store frequently used client data, such as vertex array data, in high-performance server memory. GL buffer objects provide a mechanism that clients can use to allocate, initialize, and render from such memory.

The name space for buffer objects is the unsigned integers, with zero reserved for the GL. A buffer object is created by binding an unused name to ARRAY_BUFFER_ARB. The binding is effected by calling

```
    void BindBufferARB(enum target, uint buffer);
```

with <target> set to ARRAY_BUFFER_ARB and <buffer> set to the unused name. The resulting buffer object is a new state vector, initialized with a zero-sized memory buffer, and comprising the state values listed in Table BufObj1.

Name	Type	Initial Value	Legal Values
BUFFER_SIZE_ARB	integer	0	any non-negative integer
BUFFER_USAGE_ARB	enum	STATIC_DRAW_ARB	STREAM_DRAW_ARB, STREAM_READ_ARB, STREAM_COPY_ARB, STATIC_DRAW_ARB, STATIC_READ_ARB, STATIC_COPY_ARB, DYNAMIC_DRAW_ARB, DYNAMIC_READ_ARB, DYNAMIC_COPY_ARB
BUFFER_ACCESS_ARB	enum	READ_WRITE_ARB	READ_ONLY_ARB, WRITE_ONLY_ARB, READ_WRITE_ARB
BUFFER_MAPPED_ARB	boolean	FALSE	TRUE, FALSE
BUFFER_MAP_POINTER_ARB	void*	NULL	address

Table BufObj1: Buffer object parameters and their values.

BindBufferARB may also be used to bind an existing buffer object. If the bind is successful no change is made to the state of the newly bound buffer object, and any previous binding to <target> is broken.

While a buffer object is bound, GL operations on the target to which it is bound affect the bound buffer object, and queries of the target to which a buffer object is bound return state from the bound object.

In the initial state the GL-reserved name zero is bound to ARRAY_BUFFER_ARB. There is no buffer object corresponding to the name zero, so client attempts to modify or query buffer object state for the target ARRAY_BUFFER_ARB while zero is bound will generate GL errors.

Buffer objects are deleted by calling

```
    void DeleteBuffersARB(sizei n, const uint *buffers);
```

<buffers> contains <n> names of buffer objects to be deleted. After a buffer object is deleted it has no contents, and its name is again unused. Unused names in <buffers> are silently ignored, as is the value zero.

```
    The command

        void GenBuffersARB(sizei n, uint *buffers);

    returns <n> previously unused buffer object names in <buffers>.
    These names are marked as used, for the purposes of GenBuffersARB
    only, but they acquire buffer state only when they are first bound,
    just as if they were unused.

    While a buffer object is bound, any GL operations on that object
    affect any other bindings of that object.  If a buffer object is
    deleted while it is bound, all bindings to that object in the current
    context (i.e. in the thread that called DeleteBuffers) are reset to
    bindings to buffer zero.  Bindings to that buffer in other contexts
    and other threads are not affected, but attempting to use a deleted
    buffer in another thread produces undefined results, including but
    not limited to possible GL errors and rendering corruption.  Using a
    deleted buffer in another context or thread may not, however, result
    in program termination.

    The data store of a buffer object is created and initialized by
    calling

        void BufferDataARB(enum target, sizeiptrARB size,
                           const void *data, enum usage);

    with <target> set to ARRAY_BUFFER_ARB, <size> set to the size of the
    data store in basic machine units, and <data> pointing to the
    source data in client memory.  If <data> is non-null, then the source
    data is copied to the buffer object's data store.  If <data> is null,
    then the contents of the buffer object's data store are undefined.

    <usage> is specified as one of nine enumerated values, indicating
    the expected application usage pattern of the data store.  The
    values are:

        STREAM_DRAW_ARB    The data store contents will be specified once
                           by the application, and used at most a few
                           times as the source of a GL (drawing) command.
        STREAM_READ_ARB    The data store contents will be specified once
                           by reading data from the GL, and queried at
                           most a few times by the application.
        STREAM_COPY_ARB    The data store contents will be specified once
                           by reading data from the GL, and used at most
                           a few times as the source of a GL (drawing)
                           command.
        STATIC_DRAW_ARB    The data store contents will be specified once
                           by the application, and used many times as the
                           source for GL (drawing) commands.
        STATIC_READ_ARB    The data store contents will be specified once
                           by reading data from the GL, and queried many
                           times by the application.
        STATIC_COPY_ARB    The data store contents will be specified once
                           by reading data from the GL, and used many
                           times as the source for GL (drawing) commands.
```

DYNAMIC_DRAW_ARB	The data store contents will be respecified repeatedly by the application, and used many times as the source for GL (drawing) commands.
DYNAMIC_READ_ARB	The data store contents will be respecified repeatedly by reading data from the GL, and queried many times by the application.
DYNAMIC_COPY_ARB	The data store contents will be respecified repeatedly by reading data from the GL, and used many times as the source for GL (drawing) commands.

<usage> is provided as a performance hint only. The specified usage value does not constrain the actual usage pattern of the data store.

BufferDataARB deletes any existing data store, and sets the values of the buffer object's state variables to:

Name	Value
BUFFER_SIZE_ARB	<size>
BUFFER_USAGE_ARB	<usage>
BUFFER_ACCESS_ARB	READ_WRITE_ARB
BUFFER_MAPPED_ARB	FALSE
BUFFER_MAP_POINTER_ARB	NULL

Clients must align data elements consistent with the requirements of the client platform, with an additional base-level requirement that an offset within a buffer to a datum comprising N basic machine units be a multiple of N.

If the GL is unable to create a data store of the requested size, the error OUT_OF_MEMORY is generated.

To modify some or all of the data contained in a buffer object's data store, the client may use the command

```
    void BufferSubDataARB(enum target, intptrARB offset,
                          sizeiptrARB size, const void *data);
```

with <target> set to ARRAY_BUFFER_ARB. <offset> and <size> indicate the range of data in the buffer object that is to be replaced, in terms of basic machine units. <data> specifies a region of client memory <size> basic machine units in length, containing the data that replace the specified buffer range. An error is generated if <offset> or <size> is less than zero, or if <offset> + <size> is greater than the value of BUFFER_SIZE_ARB.

The entire data store of a buffer object can be mapped into the client's address space by calling

```
    void *MapBufferARB(enum target, enum access);
```

with <target> set to ARRAY_BUFFER_ARB. If the GL is able to map the buffer object's data store into the client's address space, MapBufferARB returns the pointer value to the data store. Otherwise MapBufferARB returns NULL, and the error OUT_OF_MEMORY is generated. <access> is specified as one of READ_ONLY_ARB, WRITE_ONLY_ARB, or

```
    READ_WRITE_ARB, indicating the operations that the client may perform
    on the data store through the pointer while the data store is mapped.

    MapBufferARB sets the following buffer object state values:

        Name                   Value
        ----                   -----
        BUFFER_ACCESS_ARB      <access>
        BUFFER_MAPPED_ARB      TRUE
        BUFFER_MAP_POINTER_ARB pointer to the data store

    It is an INVALID_OPERATION error to map a buffer data store that is
    in the mapped state.

    Non-null pointers returned by MapBufferARB may be used by the client
    to modify and query buffer object data, consistent with the access
    rules of the mapping, while the mapping remains valid.  No GL error
    is generated if the pointer is used to attempt to modify a
    READ_ONLY_ARB data store, or to attempt to read from a WRITE_ONLY_ARB
    data store, but operation may be slow and system errors (possibly
    including program termination) may result.  Pointer values returned
    by MapBufferARB may not be passed as parameter values to GL commands.
    For example, they may not be used to specify array pointers, or to
    specify or query pixel or texture image data; such actions produce
    undefined results, although implementations may not check for such
    behavior for performance reasons.

    It is an INVALID_OPERATION error to call BufferSubDataARB to modify
    the data store of a mapped buffer.

    Mappings to the data stores of buffer objects may have nonstandard
    performance characteristics.  For example, such mappings may be
    marked as uncacheable regions of memory, and in such cases reading
    from them may be very slow.  To ensure optimal performance, the
    client should use the mapping in a fashion consistent with the values
    of BUFFER_USAGE_ARB and BUFFER_ACCESS_ARB.  Using a mapping in a
    fashion inconsistent with these values is liable to be multiple
    orders of magnitude slower than using normal memory.

    After the client has specified the contents of a mapped data store,
    and before the data in that store are dereferenced by any GL commands,
    the mapping must be relinquished by calling

        boolean UnmapBufferARB(enum target);

    with <target> set to ARRAY_BUFFER_ARB.  Unmapping a mapped buffer
    object invalidates the pointers to its data store and sets the
    object's BUFFER_MAPPED_ARB state to FALSE and its
    BUFFER_MAP_POINTER_ARB state to NULL.

    UnmapBufferARB returns TRUE unless data values in the buffer's data
    store have become corrupted during the period that the buffer was
    mapped.  Such corruption can be the result of a screen resolution
    change or other window-system-dependent event that causes system
    heaps such as those for high-performance graphics memory to be
    discarded.  GL implementations must guarantee that such corruption
    can occur only during the periods that a buffer's data store is
```

mapped. If such corruption has occurred, UnmapBufferARB returns FALSE, and the contents of the buffer's data store become undefined.

It is an INVALID_OPERATION error to explicitly unmap a buffer data store that is in the unmapped state. Unmapping that occurs as a side effect of buffer deletion or reinitialization is not an error, however."

2.8A.1 Vertex Arrays in Buffer Objects

Blocks of vertex array data may be stored in buffer objects with the same format and layout options supported for client-side vertex arrays. However, it is expected that GL implementations will (at minimum) be optimized for data with all components represented as floats, as well as for color data with components represented as either floats or unsigned bytes.

A buffer object binding point is added to the client state associated with each vertex array type. The client does not directly specify the bindings to with these new binding points. Instead, the commands that specify the locations and organizations of vertex arrays copy the buffer object name that is bound to ARRAY_BUFFER_ARB to the binding point corresponding to the vertex array of the type being specified. For example, the NormalPointer command copies the value of ARRAY_BUFFER_BINDING_ARB (the queriable name of the buffer binding corresponding to the target ARRAY_BUFFER_ARB) to the client state variable NORMAL_ARRAY_BUFFER_BINDING_ARB.

If EXT_vertex_shader is defined, then the command VariantArrayEXT(uint id, ...) copies the value of ARRAY_BUFFER_BINDING_ARB to the buffer object binding point corresponding to variant array <id>.

If ARB_vertex_program is defined, then the command VertexAttribPointerARB(int attrib, ...) copies the value of ARRAY_BUFFER_BINDING_ARB to the buffer object binding point corresponding to vertex attrib array <attrib>.

If ARB_vertex_blend is defined, then the command WeightPointerARB copies the value of ARRAY_BUFFER_BINDING_ARB to WEIGHT_ARRAY_BUFFER_BINDING_ARB.

Rendering commands ArrayElement, DrawArrays, DrawElements, DrawRangeElements, MultiDrawArrays, and MultiDrawElements operate as previously defined, except that data for enabled vertex, variant, and attrib arrays are sourced from buffers if the array's buffer binding is non-zero. When an array is sourced from a buffer object, the pointer value of that array is used to compute an offset, in basic machine units, into the data store of the buffer object. This offset is computed by subtracting a null pointer from the pointer value, where both pointers are treated as pointers to basic machine units.

It is acceptable for vertex, variant, or attrib arrays to be sourced from any combination of client memory and various buffer objects during a single rendering operation.

It is an INVALID_OPERATION error to source data from a buffer object that is currently mapped.

2.8B.1 Array Indices in Buffer Objects
--

Blocks of array indices may be stored in buffer objects with the same format options that are supported for client-side index arrays. Initially zero is bound to ELEMENT_ARRAY_BUFFER_ARB, indicating that DrawElements and DrawRangeElements are to source their indices from arrays passed as their <indices> parameters, and that MultiDrawElements is to source its indices from the array of pointers to arrays passed in as its <indices> parameter.

A buffer object is bound to ELEMENT_ARRAY_BUFFER_ARB by calling

```
    void BindBufferARB(enum target, uint buffer);
```

with <target> set to ELEMENT_ARRAY_BUFFER_ARB, and <buffer> set to the name of the buffer object. If no corresponding buffer object exists, one is initialized as defined in Section 2.8A.

The commands BufferDataARB, BufferSubDataARB, MapBufferARB, and UnmapBufferARB may all be used with <target> set to ELEMENT_ARRAY_BUFFER_ARB. In such event, these commands operate in the same fashion as described in section 2.8A, but on the buffer currently bound to the ELEMENT_ARRAY_BUFFER_ARB target.

While a non-zero buffer object name is bound to ELEMENT_ARRAY_BUFFER_ARB, DrawElements and DrawRangeElements source their indices from that buffer object, using their <indices> parameters as offsets into the buffer object in the same fashion as described in section 2.8A1. MultiDrawElements also sources its indices from that buffer object, using its <indices> parameter as a pointer to an array of pointers that represent offsets into the buffer object.

Buffer objects created by binding an unused name to ARRAY_BUFFER_ARB and to ELEMENT_ARRAY_BUFFER_ARB are formally equivalent, but the GL may make different choices about storage implementation based on the initial binding. In some cases performance will be optimized by storing indices and array data in separate buffer objects, and by creating those buffer objects with the corresponding binding points."

Additions to Chapter 3 of the 1.4 Specification (Rasterization)

None

Additions to Chapter 4 of the 1.4 Specification (Per-Fragment Operations and the Frame Buffer)

None

Additions to Chapter 5 of the 1.4 Specification (Special Functions)

Added to section 5.4, as part of the discussion of what commands are compiled into display lists:

"Commands that are used to create, manage, and query buffer objects are not included in display lists, but are executed immediately. These commands are BindBufferARB, DeleteBuffersARB, GenBuffersARB, IsBufferARB, BufferDataARB, BufferSubDataARB, MapBufferARB, UnmapBufferARB, GetBufferParameterivARB, GetBufferSubDataARB, and GetBufferPointervARB.

GL commands that source data from buffer objects dereference the buffer object data in question at display list compile time, rather than encoding the buffer ID and buffer offset into the display list. Only GL commands that are executed immediately, rather than being compiled into a display list, are permitted to use a buffer object as a data sink."

Additions to Chapter 6 of the 1.4 Specification (State and State Requests)

Added to section 6.1 in a subsection titled Buffer Object Queries:

"The command

```
    boolean IsBufferARB(uint buffer);
```

returns TRUE if <buffer> is the name of an buffer object. If <buffer> is zero, or if <buffer> is a non-zero value that is not the name of an buffer object, IsBufferARB return FALSE.

The command

```
    void GetBufferSubDataARB(enum target, intptrARB offset,
                             sizeiptrARB size, void *data);
```

queries the data contents of a buffer object. <target> is ARRAY_BUFFER_ARB. <offset> and <size> indicate the range of data in the buffer object that is to be queried, in terms of basic machine units. <data> specifies a region of client memory, <size> basic machine units in length, into which the data is to be retrieved.

An error is generated if GetBufferSubDataARB is executed for a buffer object that is currently mapped.

While the data store of a buffer object is mapped, the pointer to the data store can be queried by calling

```
    void GetBufferPointervARB(enum target, enum pname, void **params);
```

with <target> set to ARRAY_BUFFER_ARB and <pname> set to BUFFER_MAP_POINTER_ARB. The single buffer map pointer is returned in <params>. GetBufferPointervARB returns the NULL pointer value if the buffer's data store is not currently mapped, or if the requesting client did not map the buffer object's data store, and the implementation is unable to support mappings on multiple clients."

Added to the list of queries in section 6.1.3, Enumerated Queries:

    "void GetBufferParameterivARB(enum target, enum pname, int *params);"

Errors

INVALID_ENUM is generated if the <target> parameter of BindBufferARB, BufferDataARB, BufferSubDataARB, MapBufferARB, UnmapBufferARB, GetBufferSubDataARB, GetBufferParameterivARB, or GetBufferPointervARB is not ARRAY_BUFFER_ARB or ELEMENT_ARRAY_BUFFER_ARB.

INVALID_VALUE is generated if the <n> parameter of DeleteBuffersARB or GenBuffersARB is negative.

INVALID_VALUE is generated if the <size> parameter of BufferDataARB, BufferSubDataARB, or GetBufferSubDataARB is negative.

INVALID_OPERATION is generated if BufferDataARB, BufferSubDataARB, MapBufferARB, UnmapBufferARB, GetBufferSubDataARB, GetBufferParameterivARB, or GetBufferPointervARB is executed while zero is bound to the <target> parameter.

OUT_OF_MEMORY may be generated if the data store of a buffer object cannot be allocated because the <size> argument of BufferDataARB is too large.

OUT_OF_MEMORY may be generated when MapBufferARB is called if the data store of the buffer object in question cannot be mapped. This may occur for a variety of system-specific reasons, such as the absence of sufficient remaining virtual memory.

INVALID_ENUM is generated if the <usage> parameter of BufferDataARB is not STREAM_DRAW_ARB, STREAM_READ_ARB, STREAM_COPY_ARB, STATIC_DRAW_ARB, STATIC_READ_ARB, STATIC_COPY_ARB, DYNAMIC_DRAW_ARB, DYNAMIC_READ_ARB, or DYNAMIC_COPY_ARB.

INVALID_VALUE is generated if the <offset> parameter to BufferSubDataARB or GetBufferSubDataARB is negative.

INVALID_VALUE is generated if the <offset> and <size> parameters of BufferSubDataARB or GetBufferSubDataARB define a region of memory that extends beyond that allocated by BufferDataARB.

INVALID_OPERATION is generated if MapBufferARB is executed for a buffer that is already mapped.

INVALID_OPERATION is generated if UnmapBufferARB is executed for a buffer that is not currently mapped.

INVALID_ENUM is generated if the <access> parameter of MapBufferARB is not READ_ONLY_ARB, WRITE_ONLY_ARB, or READ_WRITE_ARB.

INVALID_ENUM is generated if the <pname> parameter of GetBufferParameterivARB is not BUFFER_SIZE_ARB, BUFFER_USAGE_ARB, BUFFER_ACCESS_ARB, or BUFFER_MAPPED_ARB.

INVALID_ENUM is generated if the <pname> parameter of GetBufferPointervARB is not BUFFER_MAP_POINTER_ARB.

INVALID_OPERATION may be generated if any of the commands defined in this extension is executed between the execution of Begin and the corresponding execution of End.

INVALID_OPERATION is generated if a buffer object that is currently mapped is used as a source of GL render data, or as a destination of GL query data.

INVALID_OPERATION is generated if BufferSubDataARB is used to modify the data store contents of a mapped buffer, or if GetBufferSubDataARB is used to query to data store contents of a mapped buffer.

New State

(table 6.7, Vertex Array Data, p. 222)

Get Value	Type	Get Command	Initial Value	Sec	Attribute
ARRAY_BUFFER_BINDING_ARB	Z+	GetIntegerv	0	2.8A	vertex-array

Usage Examples

These examples illustrate various usages. In all cases a rendering loop is included, and array parameters are initialized inside the loop as would be required if multiple array rendering operations were performed in the loops. (Though only one operation is shown.)

Convenient macro definition for specifying buffer offsets:

```
    #define BUFFER_OFFSET(i) ((char *)NULL + (i))
```

Traditional vertex arrays:

```
    // Create system memory buffer
    data = malloc(320);

    // Fill system memory buffer
    ...

    // Frame rendering loop
    while (...) {

        // Define arrays
        VertexPointer(4, FLOAT, 0, data);
        ColorPointer(4, UNSIGNED_BYTE, 0, data+256);

        // Enable arrays
        EnableClientState(VERTEX_ARRAY);
        EnableClientState(COLOR_ARRAY);

        // Draw arrays
        DrawArrays(TRIANGLE_STRIP, 0, 16);

        // Disable arrays
        DisableClientState(VERTEX_ARRAY);
        DisableClientState(COLOR_ARRAY);

        // Other rendering commands
        ...

    }

    // Free system memory buffer
    free(data);
```

Vertex arrays using a buffer object:

```
    // Create system memory buffer
    data = malloc(320);

    // Fill system memory buffer
    ...

    // Create buffer object
    BindBufferARB(ARRAY_BUFFER_ARB, 1);

    // Initialize data store of buffer object
    BufferDataARB(ARRAY_BUFFER_ARB, 320, data, STATIC_DRAW_ARB);

    // Free system memory buffer
    free(data);

    // Frame rendering loop
    while (...) {

        // Define arrays
        BindBufferARB(ARRAY_BUFFER_ARB, 1);
        VertexPointer(4, FLOAT, 0, BUFFER_OFFSET(0));
        ColorPointer(4, UNSIGNED_BYTE, 0, BUFFER_OFFSET(256));

        // Enable arrays
        EnableClientState(VERTEX_ARRAY);
        EnableClientState(COLOR_ARRAY);

        // Draw arrays
        DrawArrays(TRIANGLE_STRIP, 0, 16);

        // Disable arrays
        DisableClientState(VERTEX_ARRAY);
        DisableClientState(COLOR_ARRAY);

        // Other rendering commands
        ...

    }

    // Delete buffer object
    int buffer[1] = {1};
    DeleteBuffersARB(1, buffer);
```

Code that works with and without buffer objects:

```
        // Create system memory buffer
        data = malloc(320);

        // Fill system memory buffer
        ...

        // Initialize buffer object, and null the data pointer
#ifdef USE_BUFFER_OBJECTS
        BindBufferARB(ARRAY_BUFFER_ARB, 1);
        BufferDataARB(ARRAY_BUFFER_ARB, 320, data, STATIC_DRAW_ARB);
        free(data);
        data = NULL;
#endif

        // Frame rendering loop
        while (...) {

            // Define arrays
#ifdef USE_BUFFER_OBJECTS
            BindBufferARB(ARRAY_BUFFER_ARB, 1);
#endif
            VertexPointer(4, FLOAT, 0, data);
            ColorPointer(4, UNSIGNED_BYTE, 0, data+256);

            // Enable arrays
            EnableClientState(VERTEX_ARRAY);
            EnableClientState(COLOR_ARRAY);

            // Draw arrays
            DrawArrays(TRIANGLE_STRIP, 0, 16);

            // Disable arrays
            DisableClientState(VERTEX_ARRAY);
            DisableClientState(COLOR_ARRAY);

            // Other rendering commands
            ...

        }

        // Delete buffer object
#ifdef USE_BUFFER_OBJECTS
        int buffer[1] = {1};
        DeleteBuffersARB(1, buffer);
#else
        // Free system memory buffer
        free(data);
#endif
```

Vertex arrays using a mapped buffer object:

```
    // Frame rendering loop
    while (...) {

        // Define arrays (and create buffer object in first pass)
        BindBufferARB(ARRAY_BUFFER_ARB, 1);
        VertexPointer(4, FLOAT, 0, BUFFER_OFFSET(0));
        ColorPointer(4, UNSIGNED_BYTE, 0, BUFFER_OFFSET(256));

        // Enable arrays
        EnableClientState(VERTEX_ARRAY);
        EnableClientState(COLOR_ARRAY);

        // Initialize data store of buffer object
        BufferDataARB(ARRAY_BUFFER_ARB, 320, NULL, STREAM_DRAW_ARB);

        // Map the buffer object
        float *p = MapBufferARB(ARRAY_BUFFER_ARB, WRITE_ONLY);

        // Compute and store data in mapped buffer object
        ...

        // Unmap buffer object and draw arrays
        if (UnmapBufferARB(ARRAY_BUFFER_ARB)) {
            DrawArrays(TRIANGLE_STRIP, 0, 16);
        }

        // Disable arrays
        DisableClientState(VERTEX_ARRAY);
        DisableClientState(COLOR_ARRAY);

        // Other rendering commands
        ...

    }

    // Delete buffer object
    int buffer[1] = {1};
    DeleteBuffersARB(1, buffer);
```

Vertex arrays using a mapped buffer object for array data and an unmapped buffer object for indices:

```
    // Create system memory buffer for indices
    indexdata = malloc(400);

    // Fill system memory buffer with 100 indices
    ...

    // Create index buffer object
    BindBufferARB(ELEMENT_ARRAY_BUFFER_ARB, 2);
    BufferDataARB(ELEMENT_ARRAY_BUFFER_ARB, 400, indexdata,
            STATIC_DRAW_ARB);

    // Free system memory buffer
    free(indexdata);

    // Frame rendering loop
    while (...) {

        // Define arrays (and create buffer object in first pass)
        BindBufferARB(ARRAY_BUFFER_ARB, 1);
        VertexPointer(4, FLOAT, 0, BUFFER_OFFSET(0));
        ColorPointer(4, UNSIGNED_BYTE, 0, BUFFER_OFFSET(256));
        BindBufferARB(ELEMENT_ARRAY_BUFFER_ARB, 2);

        // Enable arrays
        EnableClientState(VERTEX_ARRAY);
        EnableClientState(COLOR_ARRAY);

        // Initialize data store of buffer object
        BufferDataARB(ARRAY_BUFFER_ARB, 320, NULL, STREAM_DRAW_ARB);

        // Map the buffer object
        float *p = MapBufferARB(ARRAY_BUFFER_ARB, WRITE_ONLY);

        // Compute and store data in mapped buffer object
        ...

        // Unmap buffer object and draw arrays
        if (UnmapBufferARB(ARRAY_BUFFER_ARB)) {
            DrawElements(TRIANGLE_STRIP, 100, UNSIGNED_INT,
                         BUFFER_OFFSET(0));
        }

        // Disable arrays
        DisableClientState(VERTEX_ARRAY);
        DisableClientState(COLOR_ARRAY);

        // Other rendering commands
        ...

    }

    // Delete buffer objects
    int buffers[2] = {1, 2};
    DeleteBuffersARB(1, buffers);
```

Mapping multiple buffers simultaneously:

```
    // Map buffers
    BindBuffer(ARRAY_BUFFER_ARB, 1);
    float *a = MapBuffer(ARRAY_BUFFER_ARB, WRITE_ONLY);
    BindBuffer(ARRAY_BUFFER_ARB, 2);
    float *b = MapBuffer(ARRAY_BUFFER_ARB, WRITE_ONLY);

    // Fill buffers
    ...

    // Unmap buffers
    BindBuffer(ARRAY_BUFFER_ARB, 1);
    if (!UnmapBufferARB(ARRAY_BUFFER_ARB)) {
        // Handle error case
    }
    BindBuffer(ARRAY_BUFFER_ARB, 2);
    if (!UnmapBufferARB(ARRAY_BUFFER_ARB)) {
        // Handle error case
    }
```

ARB Extension #26

Dependencies

Written based on the wording of the OpenGL 1.3 specification and requires OpenGL 1.3.

ARB_vertex_blend and EXT_vertex_weighting affect the definition of this extension.

ARB_matrix_palette affects the definition of this extension.

ARB_point_parameters and EXT_point_parameters affect the definition of this extension.

EXT_secondary_color affects the definition of this extension.

EXT_fog_coord affects the definition of this extension.

ARB_transpose_matrix affects the definition of this extension.

NV_vertex_program interacts with this extension.

EXT_vertex_shader interacts with this extension.

Overview

Unextended OpenGL mandates a certain set of configurable per-vertex computations defining vertex transformation, texture coordinate generation and transformation, and lighting. Several extensions have added further per-vertex computations to OpenGL. For example, extensions have defined new texture coordinate generation modes (ARB_texture_cube_map, NV_texgen_reflection, NV_texgen_emboss), new vertex transformation modes (ARB_vertex_blend, EXT_vertex_weighting), new lighting modes (OpenGL 1.2's separate specular and rescale normal functionality), several modes for fog distance generation (NV_fog_distance), and eye-distance point size attenuation (EXT/ARB_point_parameters).

Each such extension adds a small set of relatively inflexible per-vertex computations.

This inflexibility is in contrast to the typical flexibility provided by the underlying programmable floating point engines (whether micro-coded vertex engines, DSPs, or CPUs) that are traditionally used to implement OpenGL's per-vertex computations. The purpose of this extension is to expose to the OpenGL application writer a significant degree of per-vertex programmability for computing vertex parameters.

For the purposes of discussing this extension, a vertex program is a sequence of floating-point 4-component vector operations that determines how a set of program parameters (defined outside of OpenGL's Begin/End pair) and an input set of per-vertex parameters are transformed to a set of per-vertex result parameters.

The per-vertex computations for standard OpenGL given a particular set of lighting and texture coordinate generation modes (along with any state for extensions defining per-vertex computations) is, in essence, a vertex program. However, the sequence of operations is defined implicitly by the current OpenGL state settings rather than defined explicitly as a sequence of instructions.

This extension provides an explicit mechanism for defining vertex program instruction sequences for application-defined vertex programs. In order to define such vertex programs, this extension defines a vertex programming model including a floating-point 4-component vector instruction set and a relatively large set of floating-point 4-component registers.

The extension's vertex programming model is designed for efficient hardware implementation and to support a wide variety of vertex programs. By design, the entire set of existing vertex programs defined by existing OpenGL per-vertex computation extensions can be implemented using the extension's vertex programming model.

Issues

(1) What should this extension be called?

RESOLVED: ARB_vertex_program. DirectX 8 refers to its similar functionality as "vertex shaders". This is a confusing term because shaders are usually assumed to operate at the fragment or pixel level, not the vertex level.

Conceptually, what the extension defines is an application-defined program (admittedly limited by its sequential execution model) for processing vertices so the "vertex program" term is more accurate.

Some of the API machinery in this extension for describing programs should be useful for extending other OpenGL operations with programs (though other types of programs may look very different from vertex programs).

(2) What terms are important to this specification?

vertex program mode - When vertex program mode is enabled, vertices are transformed by an application-defined vertex program.

conventional GL vertex transform mode - When vertex program mode is disabled (or the extension is not supported), vertices are transformed by GL's conventional texgen, lighting, and transform state.

vertex program - An application-defined program used to transform vertices when vertex program mode is enabled.

program target - A type or class of program. This extension supports the VERTEX_PROGRAM_ARB target. Future extensions may add other program targets.

program object - An object maintained internal to OpenGL that encapsulates a program and a set of associated state. Operations performed on program objects include loading a program, binding, generating program object names, querying state, and deleting.

program name - Each program object has an associated unsigned integer, called the program name. Applications refer to a program object using the program name.

current program - Each program target may have a current program object. For vertex programs, the current program is executed whenever a vertex is specified when vertex program mode is enabled.

default program - Each program target has a default program object, referred to using a program name of zero. The current program for each program target is initially the default program for that target.

program execution environment - A set of resources, instructions, and semantic rules used to execute a program. Each program target may support one or more execution environment -- new execution environments may provide new instructions, resources, or execution rules. Program strings must specify the execution environment that should be used to execute the program.

program options - An optional feature that modifies the rules of the execution environment. Vertex programs specify the options that they require at the beginning of the program.

vertex attribute - GL state associated with vertices that can vary per vertex.

conventional vertex attributes - Per-vertex attributes used in conventional GL vertex transform mode, including colors, normals, texture coordinate sets.

generic vertex attributes - An array of 16+ 4-component vectors added by this extension. Generic vertex attributes can be used by vertex programs but are unused in conventional GL vertex transform mode.

program parameter - A set of constants that are available for vertex programs to use during their execution. Program parameters include program environment parameters, program local parameters, conventional GL state, and program constants.

program environment parameter - A set of 96+ 4-component vectors belonging to the GL context that can be used as constants during the execution of any vertex program.

program local parameter - A set of 96+ 4-component vectors belonging to a vertex program object that can be used as constants during the execution of the corresponding vertex program. Program local parameters can not be used by any other vertex programs.

program constants - Constants declared in the text of a program may be used during the execution of that program.

program temporaries - A set of 12+ 4-component vectors to hold temporary results that can be read or written during the execution of a vertex program.

program address registers - A set of 1+ 1-component integer vectors that can be used to perform variable indirect accesses to program parameter arrays during the execution of a vertex program. Address registers are specified as vectors to allow for future extensions supporting multiple address register components.

program results - A set of 4-component vectors to hold the final results of a vertex program. The program results correspond closely to the set of vertex attributes used during primitive assembly and rasterization.

program variables - Variable names used to identify a specific vertex attribute, program parameter, temporary, address register, or result.

program binding - A program statement that declares a variable and associates it with a specific vertex attribute, program parameter, or program result.

implicit binding - When an executable instruction refers to a specific vertex attribute, program parameter, program result, or constant by name, without using an explicit program binding statement. When such values are encountered, an implicit binding to an anonymous variable name is created.

program invocation - The act of implicitly or explicitly kicking off program execution. Vertex programs are invoked automatically when vertex program mode is enabled and vertices are received. Vertex programs are also invoked automatically when the current raster position is specified.

(3) What part of OpenGL do vertex programs specifically bypass?

Vertex programs bypass the following OpenGL functionality:

- The modelview and projection matrix vertex transformations.

- Vertex weighting/blending (ARB_vertex_blend).

- Normal transformation, rescaling, and normalization.

- Color material.

- Per-vertex lighting.

- Texture coordinate generation and texture matrix transformations.

- Per-vertex point size computations in ARB/EXT_point_parameters

- Per-vertex fog coordinate computations in EXT_fog_coord and NV_fog_distance.

- Client-defined clip planes.

- The normalization of AUTO_NORMAL evaluated normals

- All of the above, when computing the current raster position.

Operations not subsumed by vertex programs

- Clipping to the view frustum.

- Perspective divide (division by w).

- The viewport transformation.

- The depth range transformation.

- Front and back color selection (for two-sided lighting and coloring).

- Clamping the primary and secondary colors to [0,1].

- Primitive assembly and subsequent operations.

- Evaluators (except the AUTO_NORMAL normalization).

(5) This extension adds a set of generic vertex attributes to the existing conventional attributes. The sum of the number of generic and conventional attributes supported on a given platform may exceed the total number of per-vertex attributes supported in hardware. How should this situation be handled?

RESOLVED: Implementations may alias conventional and generic vertex attributes, where pairs of conventional and generic vertex attributes share the same storage. Such aliasing will effectively reduce the number of vertex attributes a hardware platforms. While implementations may alias attributes, that behavior is not required. To accommodate both behaviors, changing a generic vertex attribute leaves the corresponding conventional attribute undefined, and vice versa.

This undefined behavior is a compromise between the existing EXT_vertex_shader extension (which does not permit aliasing) and the NV_vertex_program extension (which requires aliasing). The mapping between generic and conventional vertex attributes is found in Table X.1 below. This mapping is taken from the NV_vertex_program specification and generalized to define behavior for >8 texture coordinate sets.

Applications that mix conventional and generic vertex attributes in a single rendering pass should be careful to avoid using attributes that may alias. To limit inadvertent use of such attributes, loading a vertex program that used a pair of attributes that may alias is guaranteed to fail. Applications requiring a small number of generic vertex attributes can always safely use generic attributes 6 and 7, and any supported attributes corresponding to unused or unsupported texture units. For example, if an implementation supports only four texture units, generic attributes 12 through 15 can always be used safely.

(6) Should there be a "VertexAttribs" entry point to specify multiple vertex attributes in one immediate mode call.

RESOLVED: No. Not providing such functionality serves to reduce the already large number of required immediate mode entry points. A "VertexAttribs" command would improve the efficiency of vertex attribute transfer, but vertex arrays or display lists should still be better.

(7) Should a full complement of data types (signed and unsigned bytes, shorts, and ints, as well as floats and doubles) be supported for vertex attributes? Should fixed-point data types be supported in both normalized (map the range to [0,1] or [-1,1]) and unnormalized form?

RESOLVED: For vertex arrays, all data type combinations are supported.

For immediate mode, a smaller subset is supported, to limit the number of immediate-mode entry points added by this extension. In fully general form, 112 immediate-mode entry points (4 sizes x 2 vector/non-vector x 14 data types) would be required.

Immediate mode support is available for non-normalized shorts, floats, and doubles for all component counts. Additionally, immediate mode support is available for 4-component vectors of all data types (normalized and unnormalized).

Note also that in immediate mode, the "N" qualifier in function names like VertexAttrib4Nub will be used to indicate that fixed-point data should be normalized.

(8) How should applications indicate that fixed-point generic vertex attribute array components should be converted to [-1,+1] or [0,1] ranges?

RESOLVED: The function VertexAttribPointerARB takes a boolean argument <normalized> that indicates whether fixed-point array data should be normalized to [-1,+1] or [0,1].

One alternate approach would have been to extend to set of enumerants to include values such as NORMALIZED_UNSIGNED_BYTE_ARB. Adding such enumerants in some sense implies that UNSIGNED_BYTE is not normalized, even though it usually is.

(9) In unextended OpenGL, calling Vertex() specifies a vertex and causes vertex transformation operations to be performed on the vertex. Should there be an equivalent method to specify a vertex using generic vertex attributes? If so, how should this be accomplished?

RESOLVED: Setting generic vertex attribute zero will always specify a vertex. Vertex*(...) and VertexAttrib*(0,...) are specified to be equivalent, whether or not vertex program mode is enabled. Allowing generic vertex attribute zero to specify a vertex allows applications to write vertex programs that use only generic attributes; otherwise, applications would have had to use Vertex() to provoke vertex processing.

(10) How is this extension different from previous vertex program extensions, such as EXT_vertex_shader or NV_vertex_program? What pitfalls are there in porting vertex programs to/from this extension?

RESOLVED: See "Interactions with NV_vertex_program" and "Interactions with EXT_vertex_shader" sections near the end of this specification.

(11) Should program parameter variables bound to GL state be updated automatically after the bound state changes? If so, when?

RESOLVED: Yes. Such variables are updated automatically prior to the next vertex program invocation with no application intervention required. A proposal to reduce the burden by requiring a manual "update state" step was considered and rejected.

(12) How should this specification handle variable bindings to Material state? Material is allowed inside a Begin/End, so material properties are technically per-vertex state.

RESOLVED: Materials can be bound only as program parameters. Changes to material properties inside a Begin/End will leave the bindings undefined until the subsequent End command. At that point, all material property bindings are guaranteed to be updated, and any material property changes up to the next Begin command are guaranteed to take effect immediately.

Supporting per-vertex material properties places additional pressure on the number of per-vertex bindings an implementation can support, which was already a problem. See issue (5).

In practice, material properties are usually not changed in this manner. Applications needing to change material properties inside a Begin/End in vertex program mode can work around this limitation by storing the color in a conventional or generic vertex attribute and modifying the vertex program accordingly.

(13) What semantic restrictions, if any, should be imposed on binding the same GL state to multiple variables? The grammar permits such bindings, but allowing this behavior means that single state updates must update multiple variables.

RESOLVED: Cases where a single state update necessarily requires updating multiple variables are disallowed. The only restriction resulting from this decision is that a single state variable can not be bound more than once in the collection of arrays that are accessed using relative addressing (at run time). The driver can and will coalesce all other bindings accessed only at fixed offsets into a single binding.

This restriction and a little driver work allows the same state variable to be used multiple times without requiring that a single state change update multiple variables.

(14) What semantic restrictions, if any, should be imposed on using multiple vertex attributes or program parameters in the same instruction?

RESOLVED: None. If the underlying hardware implementation does not support reads of multiple attributes or program parameters, the driver may need to transparently insert additional instructions and/or consume temporaries to perform the operation.

(15) How and when should related state be combined into a single program parameter binding? Additionally, should any values derived from core GL state be exposed, too?

RESOLVED: Related state should be combined when possible, as long as the binding name remains somewhat sensible. Additionally, certain pre-computed state items useful for performance reasons are also exposed. In particular, the following GL state combinations are supported:

* Light attenuation constants and the spot light exponent are combined into a single vector called "state.light[n].attenuation" (spot lights can attenuate the lit result).

* Spot light direction and cutoff angle cosine are called "state.light[n].spot.direction" (cutoff is directional information). Binding the cutoff angle itself is pretty useless, so the cosine is used.

* A pre-computed half angle for lighting with infinite lights and an infinite viewer is provided and called "state.light[n].half".

* Pre-computed products of ambient, diffuse, and specular light colors with the corresponding front or back material colors are supported, and are called "state.lightprod[n].<face>.<property>".

* Exponential fog density, linear fog start and end parameters, as well as the pre-computed reciprocal of (end-start) are combined into one vector called "state.fog.params".

* The core point size, minimum and maximum size clamps (ARB_point_parameters), and multisample fade size threshold (ARB_point_parameters) are combined into a single vector called "state.point.size".

* Precomputed transpose, inverse, and inverse transpose matrices are supported for each base matrix type.

(16) Should the initial values of temporaries and results be undefined?

RESOLVED: Since the underlying hardware differs, it was decided to leave these values uninitalized. There are a few issues related to this behavior that programs should keep in mind:

* Since any results not written by the program are undefined, programs should write to all result registers that are needed during rasterization.

* In particular, the initial vertex position result is undefined, and will remain undefined if not written by a program. To achieve proper results, vertex programs should be careful to write to all four components of the vertex position. Otherwise, primitives may be completely clipped or produce undefined results during rasterization. There is no semantic requirement that programs must write a transformed vertex position, so erroneous programs will load succesfully, but will produce undefined (and probably useless) results. Such a semantic requirement may be impossible to enforce in future language versions that support run-time branching.

* Since vertex programs may be executed when the raster position is set, any attributes not written by the program will result in undefined state in the current raster position. Programs should write to all result registers that would be used when rasterizing pixel primitives using the current raster position.

* If conventional OpenGL texture mapping operations are performed, a program should always write to the "w" coordinate of any texture coordinates result registers it needs to use. Conventional OpenGL texture accesses always use projective texture coordinates (e.g., s/q, t/q, r/q), even though q is almost always 1.0. An undefined q coordinate (coming from the "w" component of the result register) may produce undefined coordinates on the texture lookup.

(17) Should vertex programs be required to have a header token and an end token?

RESOLVED: Yes. The header token for this extension is named "!!ARBvp1.0". The ARB may standardize future language versions which would be expected to have tokens like "!!ARBvp2.0". Vertex programs must end with the "END" token.

The initial header token reminds the programmer what type of program they are writing. If vertex programs are ever read from disk files, the header token can be used to specifically identify vertex programs. The initial header tokens will also make it easier for programmers to distinguish between multiple types of vertex programs and between vertex programs and another future type of programs.

We expect that programs may be generated by concatenation of program fragments. The "END" token will hopefully reduce bugs due to specifying an incorrectly concatenated program.

(18) Should ProgramStringARB take a <program> specifier? Should ProgramLocalParameterARB and GetProgramLocalParameterARB take a <program> specifier? How about GetProgramivARB and GetProgramStringARB?

RESOLVED: No to all. Instead, these calls are specified to always query or modify the currently bound program object. Using bound objects allows GL implementations to avoid locking and name lookup overhead on each such call.

This behavior does imply that applications loading a sequence of program objects must bind each in turn.

(19) Should relative addressing be performed using an address register (load up an integer register) or by taking a floating-point scalar?

RESOLVED: Address register. It would not be a good idea to support both syntaxes simultaneously, since using a floating-point scalar may consume the only available address register in the process. The current address register syntax can be easily extended to allow for multiple integer registers and/or enable other integer operations in a later extension.

Using a floating-point index may require an extra instruction on some architectures, and would require optimization work to eliminate redundant loads. Using a floating-point index may consume one of a small number of temporary registers. On the other hand, for implementations without a dedicated address register, it may be necessary to dedicate a general-purpose register (or register component) to hold the address register contents.

(20) How should user-defined clipping be supported in this specification?

RESOLVED: User-defined clipping is not supported in standard vertex program mode. User-defined clipping support will be provided for programs that use the "position invariant" option, where all vertex transformation operations are performed by the fixed-function pipeline.

It is expected that future vertex program extensions or a future language standard may provide more powerful user clipping functionality.

The options considered were:

(1) Not at all. Does not work for applications requiring user clipping. User clipping could be supported through a language extension.

(2) Support only through the "position_invariant" option, where vertex transformation is performed by the fixed-function pipeline.

(3) Support by using the fixed-function pipeline to generate eye coordinates and perform user clipping as specified for conventional transformation. May not work properly if the vertex transformation doesn't match the standard "multiply by modelview and projection matrices" model.

(4) Project existing fixed-function clip planes into clip coordinates and perform the clip test in clip space. The clip planes would be transformed by the inverse of the projection matrix, which will not work if the projection matrix is singular.

(5) Provide a 4-component "user clip coordinate" result that can be bound by a vertex program. User clipping is performed as in unextended OpenGL, using the "user clip coordinate" in place of the non-existant eye coordinates. This approach allows an application to do user clipping in any coordinate system. Clipping would not be independent of primitive tesselation as in the conventional pipeline. Additionally, the implicit transformation of specified clip planes by the modelview matrix may be undesirable (e.g., clipping in object coordinates).

(6) Provide one or more "clip plane distance" results that can be bound by a vertex program. For conventional clipping applications, vertex programs would compute the dot products normally computed by fixed-function hardware. Additionally, this method would enable additional unconventional clipping effects. Primitives would be clipped to the portion whose interpolated clip distances are greater than or equal to zero. This approach has the same issues as (5).

(21) How should future vertex program opcodes be named?

RESOLVED: Three-character names are recommended for brevity. Three character names are not a hard-and-fast requirement; extra characters may be needed for clarity or to disambiguate instructions.

(22) Should anything be said about the precision used for carrying out the instructions?

RESOLVED: Not much; precision will vary across platforms. The minimum precision requirements (1 part in 10^5 or roughly 17 bits) are spelled out in section 2.1.1. In practice, implementations will generally provide precision comparable to that obtained using single precision floats. Documenting exact precision across implementations is difficult. Additionally, it is difficult to spell out precision requirements for "compound" operations such as DP4.

(23) Should this extension support evaluator maps for generic vertex attributes? If so, what attribute sizes should be supported? Note that such maps are not supported at all for texture units except zero.

RESOLVED: No. Evaluator support has not been consistently extended in previous extensions. For example, neither ARB_multitexture nor OpenGL 1.3 provide support for evaluators for texture units other than unit zero. Adding evaluators for generic attributes involves a large amount of new state and complexity, particularly if evaluators should be supported in general form (1, 2, 3, and 4 components, all supported data type).

(25) The number of generic vertex attributes is implementation-dependent and is at least 16. Each generic vertex attribute has a vertex array enable. Should two new entry points be provided to accept an arbitrary attribute number, or should we reserve a range of enumerants that is "large enough"?

RESOLVED: Yes. EnableVertexAttribArrayARB and DisableVertexAttribArrayARB. This allows the number of vertex attributes to be unbounded, instead of using a limited range.

(26) What limits should be imposed on the constants that can be added to or subtracted from the address register for relative addressing? Negative offsets are sometimes useful for shifting down in an array.

RESOLVED: -64 to +63 should be sufficient for the time being. Offset sizes are limited to allow offsets to be baked into device-dependent instruction encodings.

(28) What level of precision should be guaranteed for the EXP and LOG instructions? And for the EX2 and LG2 instructions?

RESOLVED: The low precision EXP and LOG instructions should give at least 10 bits (2^-11 maximum relative error). No specific treatment will be added for EX2/LG2, implying that the computations should at least meet the minimal floating-point precision required by the spec.

(29) Should incremental program compilation be supported?

RESOLVED: No. Applications can compile programs just as easily using string concatenation.

(30) Should the execution environment be identified by the program itself or as an additional "language" parameter to ProgramStringARB?

RESOLVED: Programs should identify their execution environment in the header. The header (plus any specified options) make it clear what kind of program is being defined.

(31) Should this extension provide support for character sets other than 7-bit ASCII?

RESOLVED: Provide a <format> argument to ProgramStringARB to allow for future extensions. Only ASCII will be supported by this extension; additional character sets or encodings could be supported using separate extensions.

(32) Support for "program object" functionality may be applicable to future program targets. Should this functionality be factored out into a separate extension?

RESOLVED: No, such separation is not necessary. This extension was designed to allow to easily accommodate future program target types. It would be straightforward to put program object functionality into a separate extension, but the functionality provided by that extension would be of no value by itself.

(33) Should program residency management be supported?

RESOLVED: No. This functionality can be supported in a separate extension if desired. If may be desirable to address residency management in a more general form, where an application may desire a diverse set of objects (textures, programs) to be resident at once.

(34) Should program object management APIs (GenProgramsARB, DeleteProgramsARB) work like texture objects or display lists?

RESOLVED: Texture objects.

Both approaches have their merits. Pluses for the display list model include: no need to keep around multiple indices if you want to allocate a group of object, contiguous indices may fall out on implementations that share one block allocator for textures and display lists. Pluses for the texture object model: non-contiguous indices may be more optimizable -- new objects can be mapped to empty blocks in a hash table to avoid collisions with existing objects, separate indices are more compatible with a future handle-based object paradigm, and a larger base of extensions using this model. Note that display list allocations needed to be contiguous to support CallLists, but no such requirement for texture or program objects exists for programs.

(35) Should there be support for a program object zero? With texture objects, texture object zero is "special" because it is the default texture object for each target type. Is there something like this for program objects?

RESOLVED: Yes. Like texture objects, there should be a separate program object zero for each program type. This allows applications to use vertex programs without needing to generate and manage program objects.

With texture objects, an object zero was needed for backward compatibility with pre-OpenGL 1.1 applications. There is no such requirement here, but providing an object zero nicely matches the familiar texture object model.

(36) How should this extension provide feedback on why a program failed to load?

RESOLVED: Two queries are provided. Calling GetIntegerv() with PROGRAM_ERROR_POSITION_ARB provides the offset of an offending instruction in the program string. An error position of -1 indicates that a program loaded successfully. Calling GetString() with PROGRAM_ERROR_STRING_ARB returns an implementation-dependent error string explaining the reason for the failure. The error string can be queried even on successful program loads to check for warning messages.

The error string may be kept in a static buffer managed by the GL implementation. Implementations may reuse the same buffer on subsequent calls to ProgramStringARB, so returned error strings are guaranteed to be valid only until the next such call.

(37) How does ARB_vertex_blend's WEIGHT_SUM_UNITY_ARB mode interact with this extension? This mode allows an application to specify N-1 weights, and have the Nth weight computed by the GL.

RESOLVED: The ARB_vertex_blend spec (as of May, 2002) specifies that the nth weight is automatically computed by the GL and is effectively current state. In practice, ARB_vertex_blend implementations compute the nth weight on the fly in the fixed-function transformation pipeline, implying that the ARB_vertex_blend spec may require a fix. For the purposes of this extension, the WEIGHT_SUM_UNITY_ARB enable is ignored in vertex program mode. Applications performing a vertex weighting operation in a vertex program are free to compute the extra weight in the program.

(38) Should program environment parameters be pushed and popped?

RESOLVED: No. There is no need to push and pop this large set of state, much like pixel maps. Adding a new attribute bit would have complicated logistics (would the bit be included in ALL_ATTRIB_BITS?). Having program local parameters provides a method for making localized changes to certain state simply by switching programs.

(39) How should this extension interact with color material?

RESOLVED: When color material is enabled, any bindings of material colors that track the current color should be updated when the current color is updated. In this specification, material properties can be bound only as program parameters, and any changes to the material properties inside a Begin/End leave the bindings undefined until the next End command. Similarly, any indirect changes to the material properties (through ColorMaterial) will have a similar effect.

Several other options were considered here. One option was to support per-vertex material property bindings and have programs that reference tracked material properties should get the current color. This could be handled either by broadcasting the current color to multiple vertex attributes, or recompiling the vertex program so that references to a tracked material property are redirected to the vertex color. Both such solutions are somewhat complex. A second option would be to ignore the COLOR_MATERIAL enable and instead use an "old" material color. This breaks the standard color material model. Implementations can and often do defer such updates (making an "old" color available), some conditions may cause an implementation to update of material state at odd times.

(41) What about when the execution environment involves support for other extensions? In particular, the execution environment subsumes some functionality from EXT/ARB_point_parameters, EXT_fog_coord, EXT_secondary_color, and ARB_multitexture.

RESOLVED: This extension assumes support for functionality that includes a fog coordinate, secondary color, per-vertex point sizes, and multiple texture coordinates (at least to the extent that it exposes >1 texture coordinate). All of these extensions are supported fairly widely. On some platforms, some of this functionality may require software fallbacks.

(42) How does PointSize work with vertex programs?

RESOLVED: If VERTEX_PROGRAM_POINT_SIZE_ARB is disabled, the size of points is determined by the PointSize state and is not attenuated, even if EXT_point_parameters is supported. If enabled, the point size is the point size result value, and is clamped to implementation-dependent point size limits during point rasterization.

(43) What do we say about the alpha component of the secondary color?

RESOLVED: The alpha component of the secondary color has generally been treated as zero. This extension specifies that only the R, G, and B components are added in the color sum operation, making the alpha component of the secondary color irrelevant. Other downstream extensions may allow applications to make use of this component.

(44) How are edge flags handled?

RESOLVED: Edge flags are passed through without the ability to be modified by a vertex program. Applications are free to send edge flags when vertex program mode is enabled.

(45) Should programs be C-style null-terminated strings?

RESOLVED: No. Programs should be specified as an array of GLubyte with an explicit length parameter. OpenGL has no precedent for passing null-terminated strings into the API (though GetString returns null-terminated strings). Null-terminated strings may be problematic for some programming languages.

(46) Should all existing OpenGL transform functionality and extensions be implementable as vertex programs?

RESOLVED: Yes. Vertex programs should be a complete superset of what you can do with OpenGL 1.2 and existing vertex transform extensions. To implement EXT_point_parameters, the VERTEX_PROGRAM_POINT_SIZE_ARB enable is introduced. To implement two-sided lighting, the VERTEX_PROGRAM_TWO_SIDE_ARB enable is introduced. To implement color material, applications should refer to the per-vertex color attribute in their vertex programs.

(47) Should there be a plural version of ProgramEnvParameter and ProgramLocalParameter, which would set multiple parameters in a single call?

RESOLVED: No; not necessary.

(48) Can the currently bound vertex program object be deleted or reloaded?

RESOLVED: Yes. When ProgramStringARB is called to reload a program object, subsequent program executions will use the new program. When DeleteProgramsARB deletes a currently bound program object, object zero becomes the new current program object.

(49) What happens if you transform vertices in vertex program mode, but the current program object does not contain a valid vertex program?

RESOLVED: Begin will fail with an INVALID_OPERATION error if the currently bound vertex program object does not have a valid program. The same applies to RasterPos and any command (Rect, DrawArrays, DrawElements) that implies a Begin.

Because Vertex is ignored outside of a Begin/End pair (without generating an error) it is impossible to provoke a vertex program if the current vertex program object is nonexistent or invalid. Other per-vertex parameters (for examples those set by Color, Normal, and VertexAttrib*ARB when the attribute number is not zero) are allowed since they are legal outside of a Begin/End.

(50) Discussing matrices is confusing because of row-major versus column-major issues. Can you give an example of how a matrix is bound?

RESOLVED: Assume program matrix zero were loaded with the following code:

```
// When loaded, the first row is "1, 2, 3, 4", because of column-major
// (OpenGL spec) vs. row-major (C) differences.
GLfloat matrix[16] = { 1, 5, 9,  13,
                       2, 6, 10, 14,
                       3, 7, 11, 15,
                       4, 8, 12, 16 };
glMatrixMode(GL_MATRIX0_ARB);
glLoadMatrixf(matrix);
```

Then in the program

```
!!ARBvp1.0
PARAM mat1[4] = { state.matrix.program[0] };
PARAM mat2[4] = { state.matrix.program[0].transpose };
```

mat1[0] would have (1,2,3,4), mat1[3] would have (13,14,15,16), mat2[0] would have (1,5,9,13), and mat2[3] would have (4,8,12,16).

(51) Should the new vertex program-related enables push/pop with ENABLE_BIT?

RESOLVED: Yes. Pushing and popping enable bits is easy.

(52) Should all the vertex attribute state push/pop with CURRENT_BIT?

RESOLVED: Yes.

(53) Should all the vertex attrib vertex array state push/pop with CLIENT_VERTEX_ARRAY_BIT?

RESOLVED: Yes.

(55) Should we generate an INVALID_VALUE operation if updating a vertex attribute greater than MAX_VERTEX_ATTRIBS_ARB?

RESOLVED: Yes. The other option would be to leave the behavior undefined, as with MultiTexCoord() functions. An implementation could mask or modulo the vertex attribute index with MAX_VERTEX_ATTRIB_ARB if it were a power of two. This error check will be a minor performance issue with VertexAttrib*ARB() and VertexAttribArrayARB() calls. There will be no per-vertex overhead when using vertex arrays or display lists.

(56) Should writes to program environment or local parameters during a vertex program be supported?

RESOLVED. No. Writes to program parameter registers from within a vertex program would require the execution of vertex programs to be serialized with respect to each other. This would create a severe implementation penalty for pipelined or parallel vertex program execution implementations.

(58) Should program objects be shared among rendering contexts in the same manner as display lists and texture objects?

RESOLVED: Yes.

(60) Should there be a MatrixMode or ActiveTexture-style selector for vertex attributes?

RESOLVED: No. While this would reduce the number of enumerants used by this extensions, it would create programming a hassle in lots of cases. Consider having to change the vertex attribute mode to enable a set of vertex arrays.

(61) How should queries of vertex attribute arrays work?

RESOLVED: Add new get commands. Using the existing calls would require adding 6 sets of 16+ enumerants for current state and vertex attribute array state. That's too many new enumerants. Instead, add GetVertexAttribARB and GetVertexAttribPointervARB. GetVertexAttribARB will be used to query vertex attribute array state and the current values of the generic vertex attributes. Get and GetPointerv will not return vertex attribute array state and pointers.

(63) What should be said about rendering invariances?

RESOLVED: See the Appendix A additions below.

The justification for the two rules cited is to support multi-pass rendering when using vertex programs. Different rendering passes will likely use different programs so there must be some means of guaranteeing that two different programs can generate particular identical vertex results between different passes.

In practice, this does limit the type of vertex program implementations that are possible.

For example, consider a limited hardware implementation of vertex programs that uses a different floating-point implementation than the CPU's floating-point implementation. If the limited hardware implementation can only run small vertex programs (say the hardware provides on 4 temporary registers instead of the required 12), the implementation is incorrect and non-conformant if programs that only require 4 temporary registers use the vertex program hardware, but programs that require more than 4 temporary registers are implemented by the CPU.

This is a very important practical requirement. Consider a multi-pass rendering algorithm where one pass uses a vertex program that uses only 4 temporary registers, but a different pass uses a vertex program that uses 5 temporary registers. If two programs have instruction sequences that given the same input state compute identical resulting vertex positions, the multi-pass algorithm should generate identically positioned primitives for each pass. But given the non-conformant vertex program implementation described above, this could not be guaranteed.

This does not mean that schemes for splitting vertex program implementations between dedicated hardware and CPUs are impossible. If the CPU and dedicated vertex program hardware used IDENTICAL floating-point implementations and therefore generated exactly identical results, the above described could work.

While these invariance rules are vital for vertex programs operating correctly for multi-pass algorithms, there is no requirement that conventional OpenGL vertex transform mode will be invariant with vertex program mode. A multi-pass algorithm should not assume that one pass using vertex program mode and another pass using conventional GL vertex transform mode will generate identically positioned primitives.

Consider that while the conventional OpenGL vertex program mode is repeatable with itself, the exact procedure used to transform vertices is not specified nor is the procedure's precision specified. The GL specification indicates that vertex coordinates are transformed by the modelview matrix and then transformed by the projection matrix. Some implementations may perform this sequence of transformations exactly, but other implementations may transform vertex coordinates by the composite of the modelview and projection matrices (one matrix transform instead of two matrix transforms in sequence). Given this implementation flexibility, there is no way for a vertex program author to exactly duplicate the precise computations used by the conventional OpenGL vertex transform mode.

The guidance to OpenGL application programs is clear. If you are going to implement multi-pass rendering algorithms that require certain invariances between the multiple passes, choose either vertex program mode or the conventional OpenGL vertex transform mode for your rendering passes, but do not mix the two modes.

(64) Should there be a way to guarantee position invariance with respect to conventional vertex transformation?

RESOLVED: Yes. The "OPTION ARB_position_invariant" program option addresses this issue. This program option will be available on all implementations of this extension.

John Carmack advocated the need for this.

(65) Why must RCP of 1.0 always be 1.0?

RESOLVED: This is important for 3D graphics so that non-projective textures and orthogonal projections work as expected. Basically when q or w is 1.0, things should work as expected. Stronger requirements such as "RCP of -1.0 must always be -1.0" are encouraged, but there is no compelling reason to state such requirements explicitly as is the case for "RCP of 1.0 must always be 1.0".

(66) What happens when the source scalar value for the ARL instruction is an extremely large positive or negative floating-point value? Is there a problem mapping the value to a constrained integer range?

RESOLVED: In this extension, address registers are only useful for relative addressing. The range of offsets that can be added to an address register is limited (-64 to +63) and the set of valid array indices is also limited to MAX_PROGRAM_PARAMETERS_ARB. So, the set of floating-point values that needs to be handled properly is well-constrained.

(67) How do you perform a 3-component normalize in three instructions?

RESOLVED: As follows.

```
DP3 result.w, vector, vector;     # result.w = nx^2+ny^2+nz^2
RSQ result.w, result.w;           # result.w = 1/sqrt(nx^2+ny^2+nz^2)
MUL result.xyz, result.w, vector;
```

(69) How do you compute the determinant of a 3x3 matrix in three instructions?

RESOLVED: As follows.

```
#
# Determinant of | vec0.x  vec0.y  vec0.z | into result.
#                | vec1.x  vec1.y  vec1.z |
#                | vec2.x  vec2.y  vec2.z |
#
MUL result, vec1.zxyw, vec2.yzxw;
MAD result, vec1.yzxw, vec2.zxyw, -result;
DP3 result, vec0, result;
```

(70) How do you transform a vertex position by a 4x4 matrix and then perform a homogeneous divide?

```
  RESOLVED:  As follows.

    ATTRIB  pos = vertex.position;
    TEMP    result, temp;
    PARAM   mat[4] = { state.matrix.modelview };

    DP4     result.w, pos, mat[3];
    DP4     result.x, pos, mat[0];
    DP4     result.y, pos, mat[1];
    DP4     result.z, pos, mat[2];
    RCP     temp.w, result.w;
    MUL     result, result, temp.w;
```

(71) How do you perform a vector weighting of two vectors using a single weight?

```
  RESOLVED:  As follows.

    # result = a * vec0 + (1-a) * vec1
    #        = vec1 + a * (vec0 - vec1)
    SUB result, vec0, vec1;
    MAD result, a, result, vec1;
```

*(72) How do you reduce a value to some fundamental period such as 2*PI?*

```
  RESOLVED:  As follows.

    # result = 2*PI * fraction(in/(2*PI))
    # piVec = (1/(2*PI), 2*PI, 0, 0)
    PARAM piVec = { 0.159154943, 6.283185307, 0, 0 };

    MUL result, in, piVec.x;
    EXP result, result.x;
    MUL result, result.y, piVec.y;
```

(73) How do you implement a simple ambient, specular, and diffuse infinite lighting computation with a single light and an eye-space normal?

```
  RESOLVED:  As follows.

    !!ARBvp1.0
    ATTRIB iPos         = vertex.position;
    ATTRIB iNormal      = vertex.normal;
    PARAM  mvinv[4]     = { state.matrix.modelview.invtrans };
    PARAM  mvp[4]       = { state.matrix.mvp };
    PARAM  lightDir     = state.light[0].position;
    PARAM  halfDir      = state.light[0].half;
    PARAM  specExp      = state.material.shininess;
    PARAM  ambientCol   = state.lightprod[0].ambient;
    PARAM  diffuseCol   = state.lightprod[0].diffuse;
    PARAM  specularCol  = state.lightprod[0].specular;
    TEMP   xfNormal, temp, dots;
    OUTPUT oPos         = result.position;
    OUTPUT oColor       = result.color;

    # Transform the vertex to clip coordinates.
    DP4   oPos.x, mvp[0], iPos;
    DP4   oPos.y, mvp[1], iPos;
    DP4   oPos.z, mvp[2], iPos;
    DP4   oPos.w, mvp[3], iPos;

    # Transform the normal to eye coordinates.
    DP3   xfNormal.x, mvinv[0], iNormal;
    DP3   xfNormal.y, mvinv[1], iNormal;
    DP3   xfNormal.z, mvinv[2], iNormal;

    # Compute diffuse and specular dot products and use LIT to compute
    # lighting coefficients.
    DP3   dots.x, xfNormal, lightDir;
    DP3   dots.y, xfNormal, halfDir;
    MOV   dots.w, specExp.x;
    LIT   dots, dots;

    # Accumulate color contributions.
    MAD   temp, dots.y, diffuseCol, ambientCol;
    MAD   oColor.xyz, dots.z, specularCol, temp;
    MOV   oColor.w, diffuseCol.w;
    END
```

(75) Can you perturb transformed vertex positions with a vertex program?

RESOLVED: Yes. Here is an example that performs an object-space diffuse lighting computations and perturbs the vertex position based on this lighting result. Do not take this example too seriously.

```
!!ARBvp1.0
#
# Program environment parameters:
# c[0].xyz = normalized light direction in object-space
#
# outputs diffuse illumination for color and perturbed position
#
ATTRIB iPos         = vertex.position;
ATTRIB iNormal      = vertex.normal;
PARAM  mvp[4]       = { state.matrix.mvp };
PARAM  lightDir     = program.env[0];
PARAM  diffuseCol   = { 1, 1, 0, 1 };
TEMP   temp;
OUTPUT oPos         = result.position;
OUTPUT oColor       = result.color;

DP3   temp, lightDir, iNormal;
MUL   oColor.xyz, temp, diffuseCol;
MAX   temp, temp, 0;            # clamp dot product to zero
MUL   temp, temp, iNormal;      # align in direction of normal
MUL   temp, temp, 0.125;        # scale displacement by 1/8
SUB   temp, temp, iPos;         # perturb
DP4   oPos.x, mvp[0], temp;     # xform using perturbed position
DP4   oPos.y, mvp[1], temp;
DP4   oPos.z, mvp[2], temp;
DP4   oPos.w, mvp[3], temp;
END
```

(76) Should this extension provide any method for updating program parameters in a program itself?

RESOLVED: No. NV_vertex_program provided a special mechanism to do this using a "vertex state program" manually executed by calling ExecuteProgramNV. This capability has not proven itself particularly useful to date.

(78) Should there be a different ProgramStringARB call for every distinct program target? Arguably, 1D, 2D, and 3D textures each have their own TexImage command for specifying their image data.

RESOLVED: No. All program objects can/should be loaded with ProgramStringARB. We expect the string to be a sufficient to express any kind of programmability.

Moreover, the 1D, 2D, and 3D TexImage commands describe the image being specified as opposed to the texture target being updated. With cube map textures, there are six face texture targets that use the TexImage2D command but not with the TEXTURE_2D target.

(79) This extension introduces a collection of new matrices for use by vertex programs (and possibly other programs as well). What should these matrices be called?

RESOLVED: Program matrices. These matrices are referred to as "tracking matrices" in NV_vertex_program, but the functionality is equivalent.

(80) With ARB_vertex_blend and EXT_vertex_weighting, there are multiple modelview matrices. This extension provides a single "MVP" matrix, defined to be the product of modelview matrix 0 and the projection matrices. Should this extension instead provide one MVP matrix per modelview matrix?

RESOLVED: No. Providing multiple MVP matrices allows applications to do N transformations into clip space and then one weighting operation, instead of N transformations into eye space, a weighting operation, and then a single transformation into clip space. This would potentially save instructions, but this optimization would be of no value if the program did any other operations that required eye coordinates.

Note also that the MVP transformations are likely general 4x4 matrix multiplies (4 DP4 instructions per transform). On the other hand, object and eye coordinates are often 3D coordinates with a constant W of 1.0. So each transformation to eye coordinates may require only 3 DP4 instructions, in which case the comparison may be 4N instructions (clip weighting) vs. 3N+4 (eye weighting).

(81) Should variable declarations be allowed to be anywhere within the program body, or should they instead be required to be done at the beginning of the program? Should the possibility of branching in a future standard affect this resolution?

RESOLVED: Declarations will be allowed anywhere in the program text; the only ordering requirement is that the declaration of a variable must precede its use in the program text. Requiring up-front variable declarations may require multiple passes for applications that build programs on the fly.

While declarations can appear anywhere in the program body, they are not executable statements. Any corresponding bindings (including constant initializations) are resolved before the program executes. The bindings will be resolved even if a program were to "branch around" a declaration.

(82) Should address register variables be treated as vectors? If so, should a variable number of components (up to four) be supported by this extension?

RESOLVED: In the future, four-component address vectors may be supported, and vector notation is used for forward compatibility. Using this notation makes address registers consistent with all the other vector data types in this extension. However, support for more than one usable component will be left for future extensions, but could be added via a program option or in a new language revision (e.g., !!ARBvp2.0).

(83) Should program local parameters be logically connected to the program string or the program object?

RESOLVED: Program local parameters are properties of a program object. Their values persist even after a new program is loaded into the object. This model does allow applications to recompile the program in a given object based on certain rendering settings without having to re-initialize any state stored in the object.

(84) Should this extension provide a method to specify "anonymous" program local parameters and query an index into the program parameter array.

RESOLVED: No. It would be nice to declare a variable in a program such as

```
PARAM foo = program.local;  # note no index in the array
```

after which an application could query the location of "foo" in the program local parameter array. However, given that local parameters persist even across program loads, it would be difficult to specify what program local parameter "foo" would be assigned to.

(85) EXT_vertex_weighting provides a single vertex blend weight. ARB_vertex_blend generalizes this concept to a weight vector. Both pieces of state are specified separately, and could be thought of as distinct. Should distinct bindings be provided in this extension?

RESOLVED: No. No current implementation supports both extensions, but the vendors involved in this standardization process agree that the state should not be considered distinct. If an implementation supported both extensions, the APIs would modify the same state.

(86) Should this extension provide functionality for variable aliasing? If so, how should it be specified and what types of variables can be aliasesed?

RESOLVED: Yes, for all variable types. The syntax is a simple text replacement:

```
ALIAS a = b;
```

This functionality allows applications to "share" variables, and thereby exceed implementation-dependent limits on the number of variable declarations. This may be particularly significant for temporaries, where the limit on the number of variables may be fairly low.

(87) How do you determine whether a given program option is supported by the GL implementation?

RESOLVED: Program options may be introduced in OpenGL extensions and may be added to future OpenGL specifications. An option will be supported if and only if (1) the corresponding OpenGL extension appears in the implementation-dependent EXTENSIONS string or (2) the option is documented in the OpenGL specification version corresponding to the implementation's VERSION string.

The ARB_position_invariant option is provided by this extension, and will always be available (provided this extension is supported).

(88) What's the deal with binding the alpha component of light colors, fog colors, and material colors (other than diffuse)? They don't do anything, right?

RESOLVED: The GL state for these different colors includes alpha components, which will be returned by queries. However, in the conventional OpenGL pipeline, most of these alpha components are effectively ignored. However, since they are present in the GL state, they will be exposed in bindings. What is done with these alpha values in program mode is completely up to the vertex program.

Vertex programs need to be careful to ensure that the alpha component is computed correctly when evaluating lighting equations. When accumulating light contributions, it may be necessary to use write masks to disable writes to the alpha component.

(89) The LOG instruction takes the logarithm of the absolute value of its operand while the LG2 instruction takes the logarithm of the operand itself. In LG2, the logarithm of negative numbers is undefined.

RESOLVED: The LOG instruction is present for (1) compatibility with NV_vertex_program and DirectX 8 languages and (2) because it may outperform LG2 on some platforms. For compatibility, it is defined to behave identically to existing languages.

(90) With vertex programs, fog coordinates and point sizes can be computed on a per-vertex basis. How are the fog coordinates and point sizes associated with vertices introduced by clipping computed?

RESOLVED: Fog coordinates and point sizes for clipped vertices are computed by interpolating the computed values at the original vertices in exactly the same manner as colors and texture coordinates are interpolated in section 2.13.8 of the OpenGL 1.3 specification.

(91) Vertex programs support only RGBA colors, but do not support color index inputs or results. What happens if an application uses vertex programs in color index mode.

RESOLVED: The results of vertex program execution are undefined if the GL is in color index mode.

(92) Should automatic normalization of evaluated normals (AUTO_NORMAL) be supported when the GL is in vertex program mode?

RESOLVED: Automatic normalization of normals will be disabled in vertex program mode. The current vertex program can easily normalize the normal if required. This can lead to greater efficiency if the vertex program transforms the normal to another coordinate system such as eye-space with a transform that preserves vector length. Then a single normalize after transform is more efficient than normalizing after evaluation and normalizing again after transform. Conceptually, the normalize mandated for AUTO_NORMAL in section 5.1 is just one of the many transformation operations subsumed by vertex programs.

(93) This extension allows applications to name their own variables. What keywords should be reserved?

RESOLVED: Instruction names and declaration keywords (e.g., PARAM) will be reserved. Additionally, since attribute, parameter, and result bindings are allowed in the program text, the binding prefix keywords "vertex", "state", "program", and "result" are reserved to simplify parsing. This prevents the need to distinguish between "vertex.position" ("vertex" as a binding) and "vertex.xyzw" ("vertex" as a variable).

(94) When counting the number of program parameter bindings, multiple constant vectors with the same components are counted only once. How is this determined?

RESOLVED: The implementation does a numerical comparison after the specified constants are converted to an internal floating-point representation. Due to floating-point representation limits, such conversions are not always precise. Constants specified with different text that are "equivalent" (e.g., "12" and "1.2E+01") are not guaranteed to resolve to the same value. Additionally, constants that are not "equivalent" but have only small relative differences (e.g., "200000000" and "200000001") may end up resolving to the same value. Constants specified with the same text should always be identical.

(95) What characters are allowed in identifier names?

RESOLVED: Letters ("A"-"Z", "a"-"z"), numbers ("0"-"9"), underscores ("_"), and dollar signs ("$").

(96) How should future programmability extensions interact with this one?

RESOLVED: Future programmability extensions are expected to fall in one of two classes: (1) extensions that bring programmability to new sections and (2) extensions the extend existing programmability models. The former class should introduce a new program target; the latter class would extend the functionality of an existing target.

Recommendations for extensions introducing new program targets include:

* Re-use and reference the functionality specified in this extension (or in a future OpenGL specification incorporating this extension) as much as possible, to maintain a consistent model.

* Provide a program header allowing for easy identification and versioning of programs for the new target.

Recommendations for extensions modifying existing program targets include:

* The option mechanism (section 2.14.4.5) should be used to provide minor modifications to the program language.

* The program header/version string (section 2.14.2) should be used to provide major modifications to the language, or potentially to provide a commonly used collection of options. Program header

```
        string changes should be multi-vendor extensions as much as
        possible.

      * For portability, programs should not be allowed to use extended
        language features without specifying the corresponding program
        options or program header.
```

New Procedures and Functions

```

Additions to Chapter 2 of the OpenGL 1.3 Specification (OpenGL Operation)

Modify Section 2.6, Begin/End Paradigm (p. 12)

(modify last paragraph, p. 12) ... In addition, a current normal, a current color, multiple current texture coordinate sets, and multiple generic vertex attributes may be used in processing each vertex. Normals are used by the GL in lighting calculations; the current normal is a three-dimensional vector that may be set by sending three coordinates that specify it. Texture coordinates determine how a texture image is mapped onto a primitive. Multiple sets of texture coordinates may be used to specify how multiple texture images are mapped onto a primitive. Generic vertex attributes do not have any specific function but can be used in vertex program mode (section 2.14) to compute final values for any data associated with a vertex.

Modify Section 2.6.3, GL Commands within Begin/End (p. 19)

(modify first paragraph of section, p. 19) The only GL commands that are allowed within any Begin/End pairs are the commands for specifying vertex coordinates, vertex color, normal coordinates, texture coordinates, and generic vertex attributes (Vertex, Color, Index, Normal, TexCoord, VertexAttrib*ARB), ...

Modify Section 2.7, Vertex Specification (p. 19)

(remove the "Finally" from the next-to-last paragraph, p. 20) There are several ways to set the current color. The GL stores both a current single-valued color index, and a current four-valued RGBA color. One

(add new paragraph before last paragraph of section, p. 21) Vertex programs (section 2.14) can access an array of four-component generic current vertex attributes. The first entry of this array is numbered zero, and the number of entries in the array is given by the implementation-dependent constant MAX_VERTEX_ATTRIBS_ARB. The commands

```
  void VertexAttrib{1234}{sfd}ARB(uint index, T coords);
  void VertexAttrib{123}{sfd}vARB(uint index, T coords);
  void VertexAttrib4{bsifd ubusui}vARB(uint index, T coords);
```

specify the current vertex attribute numbered <index>, whose components are named <x>, <y>, <z>, and <w>. The VertexAttrib1ARB family of commands sets the <x> coordinate to the provided single argument while setting <y> and <z> to 0 and <w> to 1. Similarly, VertexAttrib2ARB commands set <x> and <y> to the specified values, <z> to 0 and <w> to 1; VertexAttrib3ARB commands set <x>, <y>, and <z>, with <w> set to 1, and VertexAttrib4ARB commands set all four coordinates. The error INVALID_VALUE is generated if <index> is greater than or equal to MAX_VERTEX_ATTRIBS_ARB.

The commands

```
  void VertexAttrib4NubARB(uint index, T coords);
  void VertexAttrib4N{bsi ubusui}vARB(uint index, T coords);
```

also specify vertex attributes with fixed-point coordinates that are scaled to the range [0,1] or [-1,1], according to Table 2.6.

Setting generic vertex attribute zero specifies a vertex; the four vertex coordinates are taken from the values of attribute zero. A Vertex2, Vertex3, or Vertex4 command is completely equivalent to the corresponding VertexAttrib command with an index of zero. Setting any other generic vertex attribute updates the current values of the attribute. There are no current values for vertex attribute zero.

Implementations may, but do not necessarily, use the same storage for the current values of generic and certain conventional vertex attributes. When any generic vertex attribute other than zero is specified, the current values for the corresponding conventional attribute in Table X.1 become undefined. Additionally, when a conventional vertex attribute is specified, the current values for the corresponding generic vertex attribute in Table X.1 become undefined. For example, setting the current normal will leave generic vertex attribute 2 undefined, and vice versa.

Generic Attribute	Conventional Attribute	Conventional Attribute Command
0	vertex position	Vertex
1	vertex weights 0-3	WeightARB, VertexWeightEXT
2	normal	Normal
3	primary color	Color
4	secondary color	SecondaryColorEXT
5	fog coordinate	FogCoordEXT
6	-	-
7	-	-
8	texture coordinate set 0	MultiTexCoord(TEXTURE0, ...)
9	texture coordinate set 1	MultiTexCoord(TEXTURE1, ...)
10	texture coordinate set 2	MultiTexCoord(TEXTURE2, ...)
11	texture coordinate set 3	MultiTexCoord(TEXTURE3, ...)
12	texture coordinate set 4	MultiTexCoord(TEXTURE4, ...)
13	texture coordinate set 5	MultiTexCoord(TEXTURE5, ...)
14	texture coordinate set 6	MultiTexCoord(TEXTURE6, ...)
15	texture coordinate set 7	MultiTexCoord(TEXTURE7, ...)
8+n	texture coordinate set n	MultiTexCoord(TEXTURE0+n, ...)

Table X.1, Generic and Conventional Vertex Attribute Mappings. For each row, the current value of the conventional attribute becomes undefined when the corresponding generic attribute is set, and vice versa. Attribute zero corresponds to the vertex position and has no current state.

Setting any conventional vertex attribute not listed in Table X.1 (including vertex weights 4 and above, if supported) will not cause any generic vertex attribute to become undefined, and such attributes will not become undefined when any generic vertex attribute is set.

(modify the last paragraph in the section, p.21) The state required to support vertex specification consists of four floating-point numbers per texture unit to store the current texture coordinates s, t, r, and q, three floating-point numbers to store the three coordinates of the current normal, four floating-point values to store the current RGBA color, one floating-point value to store the current color index, and MAX_VERTEX_ATTRIBS_ARB-1 four-component floating-point vectors for generic vertex attributes. There is no notion of a current vertex, so no state is devoted to vertex coordinates or vertex attribute zero. The initial texture coordinates are (S,T,R,Q) = (0,0,0,1) for each texture unit. The initial current normal has coordinates (0,0,1). The initial RGBA color is (R,G,B,A) = (1,1,1,1). The initial color index is 1. The initial values for all generic vertex attributes are undefined.

Modify Section 2.8, Vertex Arrays (p. 21)

(modify first paragraph of section, p.21) The vertex specification commands described in section 2.7 accept data in almost any format, but their use requires many command executions to specify even simple geometry. Vertex data may also be placed into arrays that are stored in the client's address space. Blocks of data in these arrays may then be used to specify multiple geometric primitives through the execution of a single GL command. The client may specify up to 5 plus the values of MAX_TEXTURE_UNITS and MAX_VERTEX_ATTRIBS_ARB arrays: one each to store vertex coordinates, edge flags, colors, color indices, normals, one or more texture coordinate sets, and one or more generic vertex attributes. The commands

```
  ...

  void VertexAttribPointerARB(uint index, int size, enum type,
                              boolean normalized, sizei stride,
                              const void *pointer);
```

describe the locations and organizations...

(add after the first paragraph, p.22) The <index> parameter in the VertexAttribPointer command identifies the generic vertex attribute array being described. The error INVALID_VALUE is generated if <index> is greater than or equal to MAX_VERTEX_ATTRIBS_ARB. The <normalized> parameter in the VertexAttribPointer command identifies whether fixed-point types should be normalized when converted to floating-point. If <normalized> is TRUE, fixed-point data are converted as specified in Table 2.6; otherwise, the fixed-point values are converted directly.

(add after first paragraph, p.23) An individual generic vertex attribute array is enabled or disabled by calling one of

```
  void EnableVertexAttribArrayARB(uint index);
  void DisableVertexAttribArrayARB(uint index);
```

where <index> identifies the generic vertex attribute array to enable or disable. The error INVALID_VALUE is generated if <index> is greater than or equal to MAX_VERTEX_ATTRIBS_ARB.

(modify Table 2.4, p.23)

Command	Sizes	Normalized?	Types
VertexPointer	2,3,4	no	short, int, float, double
NormalPointer	3	yes	byte, short, int, float, double
ColorPointer	3,4	yes	byte, ubyte, short, ushort, int, uint, float, double
IndexPointer	1	no	ubyte, short, int, float, double
TexCoordPointer	1,2,3,4	no	short, int, float, double
EdgeFlagPointer	1	no	boolean
VertexAttribPointerARB	1,2,3,4	flag	byte, ubyte, short, ushort, int, uint, float, double
WeightPointerARB	>=1	yes	byte, ubyte, short, ushort, int, uint, float, double
VertexWeightPointerEXT	1	n/a	float
SecondaryColor-PointerEXT	3	yes	byte, ubyte, short, ushort, int, uint, float, double
FogCoordPointerEXT	1	n/a	float, double
MatrixIndexPointerARB	>=1	no	ubyte, ushort, uint

Table 2.4: Vertex array sizes (values per vertex) and data types. The "normalized" column indicates whether fixed-point types are accepted directly or normalized to [0,1] (for unsigned types) or [-1,1] (for singed types). For generic vertex attributes, fixed-point data are normalized if and only if the <normalized> flag is set.

(modify last paragraph, p.23) The command

```
  void ArrayElement(int i);
```

transfers the ith element of every enabled array to the GL. The effect of ArrayElement(i) is the same as the effect of the command sequence

```
       if (ARB_vertex_blend vertex weight array enabled) {
         Weight[type]vARB(vertex weight array size,
                          vertex weight array element i);
       }
       if (EXT_vertex_weighting vertex weight array enabled) {
         VertexWeight[type]vARB(vertex weight array element i);
       }
       if (normal array enabled) {
         Normal3[type]v(normal array element i);
       }
       if (color array enabled) {
         Color[size][type]v(color array element i);
       }
       if (secondary color array enabled) {
         SecondaryColor3[type]vEXT(secondary color array element i);
       }
       if (fog coordinate array enabled) {
         FogCoord[type]vEXT(fog coordinate array element i);
       }
       if (matrix index array enabled) {
         MatrixIndex[type]vARB(matrix index array size,
                               matrix index array element i);
       }
       for (j = 0; j < textureUnits; j++) {
         if (texture coordinate set j array enabled) {
           MultiTexCoord[size][type]v(TEXTURE0 + j,
                                      texture coordinate set j
                                      array element i);
       }
       if (color index array enabled) {
         Index[type]v(color index array element i);
       }
       if (edge flag array enabled) {
         EdgeFlagv(edge flag array element i);
       }
       for (j = 1; j < genericAttributes; j++) {
         if (generic vertex attribute j array enabled) {
           if (generic vertex attribute j array normalization flag
               is set, and type is not FLOAT or DOUBLE) {
             VertexAttrib[size]N[type]vARB(j, generic vertex attribute j
                                              array element i);
           } else {
             VertexAttrib[size][type]vARB(j, generic vertex attribute j
                                             array element i);
           }
         }
       }
       if (generic attribute array 0 enabled) {
         if (generic vertex attribute j array normalization flag
             is set, and type is not FLOAT or DOUBLE) {
           VertexAttrib[size]N[type]vARB(0, generic vertex attribute 0
                                            array element i);
         } else {
           VertexAttrib[size][type]vARB(0, generic vertex attribute 0
                                           array element i);
         }
       } else if (vertex array enabled) {
         Vertex[size][type]vARB(vertex array element i);
       }
```

where <textureUnits> and <genericAttributes> give the number of texture units and generic vertex attributes supported by the implementation, respectively. "[size]" and "[type]" correspond to the size and type of the corresponding array. For generic vertex attributes, it is assumed that a complete set of vertex attribute commands exists, even though not all such functions are provided by the GL. Both generic attribute array zero and the vertex array can specify a vertex if enabled, but only one such array is used. As described in section 2.7, setting a generic vertex attributes listed in Table X.1 will leave the corresponding conventional vertex attribute undefined, and vice versa.

(modify last paragraph of section, p.28) If the number of supported texture units (the value of MAX TEXTURE UNITS) is m and the number of supported generic vertex attributes (MAX_VERTEX_ATTRIBS_ARB) is n, then the client state required to implement vertex arrays consists of 5+m+n boolean enables, 5+m+n memory pointers, 5+m+n integer stride values, 4+m+n symbolic constants representing array types, 2+m+n integers representing values per element, and n boolean normalization flags. In the initial state, the enable values are each disabled, the memory pointers are each null, the strides are each zero, the array types are each FLOAT, the integers representing values per element are each four, and the normalization flags are disabled.

Modify Section 2.10, Coordinate Transformations (p. 29)

(add new paragraphs) Vertex attributes are transformed before the vertex is used to generate primitives for rasterization, establish a raster position, or generate vertices for selection or feedback. The attributes of each vertex are transformed using one of two vertex transformation modes. The first mode, described in this and subsequent sections, is GL's conventional vertex transformation model. The second mode, known as vertex program mode and described in section 2.14, transforms vertex attributes as specified in an application-supplied vertex program.

Vertex program mode is enabled and disabled, respectively, by

```
  void Enable(enum target);
```

and

```
  void Disable(enum target);
```

with <target> equal to VERTEX_PROGRAM_ARB. When vertex program mode is enabled, vertices are transformed by the currently bound vertex program as discussed in section 2.14.

When vertex program mode is disabled, vertices, normals, and texture coordinates are transformed before their coordinates are used to produce an image in the framebuffer. We begin with a description of how vertex coordinates are transformed and how the transformation is controlled in this case. The discussion that continues through section 2.13 applies when vertex program mode is disabled.

Modify Section 2.10.2, Matrices (p. 31)

(modify 1st paragraph) The projection matrix and model-view matrix are set and modified with a variety of commands. The affected matrix is determined by the current matrix mode. The current matrix mode is set with

```
  void MatrixMode(enum mode);
```

which takes one of the pre-defined constants TEXTURE, MODELVIEW, COLOR, PROJECTION, or MATRIX<i>_ARB as the argument. In the case of MATRIX<i>_ARB, <i> is an integer between 0 and <n>-1 indicating one of <n> program matrices where <n> is the value of the implementation defined constant MAX_PROGRAM_MATRICES_ARB. Such program matrices are described in section 2.14.6. TEXTURE is described later in section 2.10.2, and COLOR is described in section 3.6.3. If the current matrix mode is MODELVIEW, then matrix operations apply to the model-view matrix; if PROJECTION, then they apply to the projection matrix.

(modify last paragraph of section) The state required to implement transformations consists of a <n>-value integer indicating the current matrix mode (where <n> is 4 + the number of supported texture and program matrices), a stack of at least two 4x4 matrices for each of COLOR, PROJECTION, and TEXTURE with associated stack pointers, <n> stacks (where <n> is at least 8) of at least one 4x4 matrix for each MATRIX<i>_ARB with associated stack pointers, and a stack of at least 32 4x4 matrices with an associated stack pointer for MODELVIEW. Initially, there is only one matrix on each stack, and all matrices are set to the identity. The initial matrix mode is MODELVIEW. The initial value of ACTIVE_TEXTURE is TEXTURE0.

Modify Section 2.11, Clipping (p. 39)

(add to end of next-to-last paragraph, p. 40) ... User clipping is not supported in vertex program mode if the current program is not position-invariant (section 2.14.4.5.1). In this case, client-defined clip planes are always treated as disabled.

Modify Section 2.12, Current Raster Position (p. 42)

(modify fourth paragraph, p.42) The coordinates are treated as if they were specified in a Vertex command. If vertex program mode is enabled, the currently bound vertex program is executed, using the x, y, z, and w coordinates as the object coordinates of the vertex. Otherwise, the x, y, z, and w coordinates are transformed by the current model-view and projection matrices. These coordinates, along with current values, are used to generate a color and texture coordinates just as is done for a vertex. The color and texture coordinates produced using either method replace the color and texture coordinates stored in the current raster position's associated data. When in vertex program mode, the "x" component of the fog coordinate result replaces the current raster distance; otherwise, the distance from the origin of the eye coordinate system to the vertex as transformed by only the current model-view matrix replaces the current raster distance. The latter distance can be approximated (see section 3.10).

Rename and Modify Section 2.13.8, Color and Vertex Data Clipping (p.56)

(modify second paragraph, p.57) Texture coordinates, as well as fog coordinates and point sizes computed on a per-vertex basis, must also be clipped when a primitive is clipped. The method is exactly analogous to that used for color clipping.

Add New Section 2.14 and subsections (p. 57).

Section 2.14, Vertex Programs

The conventional GL vertex transformation model described in sections 2.10 through 2.13 is a configurable but essentially hard-wired sequence of per-vertex computations based on a canonical set of per-vertex parameters and vertex transformation related state such as transformation matrices, lighting parameters, and texture coordinate generation parameters. The general success and utility of the conventional GL vertex transformation model reflects its basic correspondence to the typical vertex transformation requirements of 3D applications.

However when the conventional GL vertex transformation model is not sufficient, the vertex program mode provides a substantially more flexible model for vertex transformation. The vertex program mode permits applications to define their own vertex programs.

A vertex program is a character string that specifies a sequence of operations to perform. Vertex program instructions are typically 4-component vector operations that operate on per-vertex attributes and program parameters. Vertex programs execute on a per-vertex basis and operate on each vertex completely independently from any other vertices. Vertex programs execute a finite fixed sequence of instructions with no branching or looping. Vertex programs execute without data hazards so results computed in one instruction can be used immediately afterwards. The result of a vertex program is a set of vertex result registers that becomes the set of transformed vertex attributes used during clipping and primitive assembly.

Vertex programs are defined to operate only in RGBA mode. The results of vertex program execution are undefined if the GL is in color index mode.

Section 2.14.1, Program Objects

The GL provides one or more program targets, each identifying a portion of the GL that can be controlled through application-specified programs. The program target for vertex programs is VERTEX_PROGRAM_ARB. Each program target has an associated program object, called the current program object. Each program target also has a default program object, which is initially the current program object.

Each program object has an associated program string. The command

```
  ProgramStringARB(enum target, enum format, sizei len,
                   const void *string);
```

updates the program string for the current program object for <target>. <format> describes the format of the program string, which must currently be PROGRAM_FORMAT_ASCII_ARB. <string> is a pointer to the array of bytes representing the program string being loaded, which need not be null-terminated. The length of the array is given by <len>. If <string> is null-terminated, <len> should not include the terminator.

When a program string is loaded, it is interpreted according to syntactic and semantic rules corresponding to the program target specified by <target>. If a program violates the syntactic or semantic restrictions of the program target, ProgramStringARB generates the error

INVALID_OPERATION.

Additionally, ProgramString will update the program error position (PROGRAM_ERROR_POSITION_ARB) and error string (PROGRAM_ERROR_STRING_ARB). If a program fails to load, the value of the program error position is set to the ubyte offset into the specified program string indicating where the first program error was detected. If the program fails to load because of a semantic restriction that is not detected until the program is fully scanned, the error position is set to the value of <len>. If a program loads successfully, the error position is set to the value negative one. The implementation-dependent program error string contains one or more error or warning messages. If a program loads succesfully, the error string may either contain warning messages or be empty.

Each program object has an associated array of program local parameters. The number and type of program local parameters is target- and implementation-dependent. For vertex programs, program local parameters are four-component floating-point vectors. The number of vectors is given by the implementation-dependent constant MAX_PROGRAM_LOCAL_PARAMETERS_ARB, which must be at least 96. The commands

```
  void ProgramLocalParameter4fARB(enum target, uint index,
                                  float x, float y, float z, float w);
  void ProgramLocalParameter4fvARB(enum target, uint index,
                                   const float *params);
  void ProgramLocalParameter4dARB(enum target, uint index,
                                  double x, double y, double z, double w);
  void ProgramLocalParameter4dvARB(enum target, uint index,
                                   const double *params);
```

update the values of the program local parameter numbered <index> belonging to the program object currently bound to <target>. For ProgramLocalParameter4fARB and ProgramLocalParameter4dARB, the four components of the parameter are updated with the values of <x>, <y>, <z>, and <w>, respectively. For ProgramLocalParameter4fvARB and ProgramLocalParameter4dvARB, the four components of the parameter are updated with the array of four values pointed to by <params>. The error INVALID_VALUE is generated if <index> is greater than or equal to the number of program local parameters supported by <target>.

Additionally, each program target has an associated array of program environment parameters. Unlike program local parameters, program environment parameters are shared by all program objects of a given target. The number and type of program environment parameters is target- and implementation-dependent. For vertex programs, program environment parameters are four-component floating-point vectors. The number of vectors is given by the implementation-dependent constant MAX_PROGRAM_ENV_PARAMETERS_ARB, which must be at least 96. The commands

```
  void ProgramEnvParameter4fARB(enum target, uint index,
                                float x, float y, float z, float w);
  void ProgramEnvParameter4fvARB(enum target, uint index,
                                 const float *params);
  void ProgramEnvParameter4dARB(enum target, uint index,
                                double x, double y, double z, double w);
  void ProgramEnvParameter4dvARB(enum target, uint index,
                                 const double *params);
```

update the values of the program environment parameter numbered <index> for the given program target <target>. For ProgramEnvParameter4fARB and ProgramEnvParameter4dARB, the four components of the parameter are updated with the values of <x>, <y>, <z>, and <w>, respectively. For ProgramEnvParameter4fvARB and ProgramEnvParameter4dvARB, the four components of the parameter are updated with the array of four values pointed to by <params>. The error INVALID_VALUE is generated if <index> is greater than or equal to the number of program environment parameters supported by <target>.

Each program target has a default program object. Additionally, named program objects can be created and operated upon. The name space for program objects is the positive integers and is shared by programs of all targets. The name zero is reserved by the GL.

A named program object is created by binding an unused program object name to a valid program target. The binding is effected by calling

```
  BindProgramARB(enum target, uint program);
```

with <target> set to the desired program target and <program> set to the unused program name. The resulting program object has a program target given by <target> and is assigned target-specific default values (see section 2.14.7 for vertex programs). BindProgramARB may also be used to bind an existing program object to a program target. If <program> is zero, the default program object for <target> is bound. If <program> is the name of an existing program object whose associated program target is <target>, the named program object is bound. The error INVALID_OPERATION is generated if <program> names an existing program object whose associated program target is anything other than <target>.

Programs objects are deleted by calling

```
  void DeleteProgramsARB(sizei n, const uint *programs);
```

<programs> contains <n> names of programs to be deleted. After a program object is deleted, its name is again unused. If a program object that is bound to any target is deleted, it is as though BindProgramARB is first executed with same target and a <program> of zero. Unused names in <programs> are silently ignored, as is the value zero.

The command

```
  void GenProgramsARB(sizei n, uint *programs);
```

returns <n> currently unused program names in <programs>. These names are marked as used, for the purposes of GenProgramsARB only, but objects are created only when they are first bound using BindProgramARB.

Section 2.14.2, Vertex Program Grammar and Semantic Restrictions

Vertex program strings are specified as an array of ASCII characters containing the program text. When a vertex program is loaded by a call to ProgramStringARB, the program string is parsed into a set of tokens possibly separated by whitespace. Spaces, tabs, newlines, carriage returns, and comments are considered whitespace. Comments begin with the

    character "#" and are terminated by a newline, a carriage return, or the
    end of the program array.

    The Backus-Naur Form (BNF) grammar below specifies the syntactically valid
    sequences for vertex programs. The set of valid tokens can be inferred
    from the grammar. The token "" represents an empty string and is used to
    indicate optional rules. A program is invalid if it contains any
    undefined tokens or characters.

    A vertex program is required to begin with the header string "!!ARBvp1.0",
    without any preceding whitespace. This string identifies the subsequent
    program text as a vertex program (version 1.0) that should be parsed
    according to the following grammar and semantic rules. Program string
    parsing begins with the character immediately following the header string.

```
<program>              ::= <optionSequence> <statementSequence> "END"

<optionSequence>       ::= <optionSequence> <option>
                         | ""

<option>               ::= "OPTION" <identifier> ";"

<statementSequence>    ::= <statementSequence> <statement>
                         | ""

<statement>            ::= <instruction> ";"
                         | <namingStatement> ";"

<instruction>          ::= <ARL_instruction>
                         | <VECTORop_instruction>
                         | <SCALARop_instruction>
                         | <BINSCop_instruction>
                         | <BINop_instruction>
                         | <TRIop_instruction>
                         | <SWZ_instruction>

```

```
<establishName>        ::= <identifier>

<establishedName>      ::= <identifier>

<identifier>           ::= see text
```

The <integer> rule matches an integer constant. The integer consists of a sequence of one or more digits ("0" through "9").

The <floatConstant> rule matches a floating-point constant consisting of an integer part, a decimal point, a fraction part, an "e" or "E", and an optionally signed integer exponent. The integer and fraction parts both consist of a sequence of one or more digits ("0" through "9"). Either the integer part or the fraction parts (not both) may be missing; either the decimal point or the "e" (or "E") and the exponent (not both) may be missing.

The <identifier> rule matches a sequence of one or more letters ("A" through "Z", "a" through "z"), digits ("0" through "9), underscores ("_"), or dollar signs ("$"); the first character must not be a number. Upper and lower case letters are considered different (names are case-sensitive). The following strings are reserved keywords and may not be used as identifiers:

    ABS, ADD, ADDRESS, ALIAS, ARL, ATTRIB, DP3, DP4, DPH, DST, END, EX2,
    EXP, FLR, FRC, LG2, LIT, LOG, MAD, MAX, MIN, MOV, MUL, OPTION, OUTPUT,
    PARAM, POW, RCP, RSQ, SGE, SLT, SUB, SWZ, TEMP, XPD, program, result,
    state, and vertex.

The error INVALID_OPERATION is generated if a vertex program fails to load because it is not syntactically correct or for one of the semantic restrictions described in the following sections.

A successfully loaded vertex program is parsed into a sequence of instructions. Each instruction is identified by its tokenized name. The operation of these instructions when executed is defined in section 2.14.5. A successfully loaded program string replaces the program string previously loaded into the specified program object. If the OUT_OF_MEMORY error is generated by ProgramStringARB, no change is made to the previous contents of the current program object.

Section 2.14.3, Vertex Program Variables

Vertex programs may access a number of different variables during their execution. The following sections define the variables that can be declared and used by a vertex program.

Explicit variable declarations allow a vertex program to establish a variable name that can be used to refer to a specified resource in subsequent instructions. A vertex program will fail to load if it declares the same variable name more than once or if it refers to a variable name that has not been previously declared in the program string.

Implicit variable declarations allow a vertex program to use the name of certain available resources by name.

Section 2.14.3.1, Vertex Attributes

Vertex program attribute variables are a set of four-component floating-point vectors holding the attributes of the vertex being processed. Vertex attribute variables are read-only during vertex program execution.

Vertex attribute variables can be declared explicitly using the <ATTRIB_statement> grammar rule, or implicitly using the <vtxAttribBinding> grammar rule in an executable instruction.

Each vertex attribute variable is bound to a single item of vertex state according to the <vtxAttrBinding> grammar rule. The set of GL state that can be bound to a vertex attribute variable is given in Table X.2. Vertex attribute variables are initialized at each vertex program invocation with the current values of the bound state.

Vertex Attribute Binding	Components	Underlying State
vertex.position	(x,y,z,w)	object coordinates
vertex.weight	(w,w,w,w)	vertex weights 0-3
vertex.weight[n]	(w,w,w,w)	vertex weights n-n+3
vertex.normal	(x,y,z,1)	normal
vertex.color	(r,g,b,a)	primary color
vertex.color.primary	(r,g,b,a)	primary color
vertex.color.secondary	(r,g,b,a)	secondary color
vertex.fogcoord	(f,0,0,1)	fog coordinate
vertex.texcoord	(s,t,r,q)	texture coordinate, unit 0
vertex.texcoord[n]	(s,t,r,q)	texture coordinate, unit n
vertex.matrixindex	(i,i,i,i)	vertex matrix indices 0-3
vertex.matrixindex[n]	(i,i,i,i)	vertex matrix indices n-n+3
vertex.attrib[n]	(x,y,z,w)	generic vertex attribute n

Table X.2: Vertex Attribute Bindings. The "Components" column indicates the mapping of the state in the "Underlying State" column. Values of "0" or "1" in the "Components" column indicate the constants 0.0 and 1.0, respectively. Bindings containing "[n]" require an integer value of <n> to select an individual item.

If a vertex attribute binding matches "vertex.position", the "x", "y", "z" and "w" components of the vertex attribute variable are filled with the "x", "y", "z", and "w" components, respectively, of the vertex position.

If a vertex attribute binding matches "vertex.normal", the "x", "y", and "z" components of the vertex attribute variable are filled with the "x", "y", and "z" components, respectively, of the vertex normal. The "w" component is filled with 1.

If a vertex attribute binding matches "vertex.color" or "vertex.color.primary", the "x", "y", "z", and "w" components of the vertex attribute variable are filled with the "r", "g", "b", and "a" components, respectively, of the vertex color.

If a vertex attribute binding matches "vertex.color.secondary", the "x", "y", "z", and "w" components of the vertex attribute variable are filled with the "r", "g", "b", and "a" components, respectively, of the vertex secondary color.

If a vertex attribute binding matches "vertex.fogcoord", the "x" component of the vertex attribute variable is filled with the vertex fog coordinate. The "y", "z", and "w" coordinates are filled with 0, 0, and 1, respectively.

If a vertex attribute binding matches "vertex.texcoord" or "vertex.texcoord[n]", the "x", "y", "z", and "w" components of the vertex attribute variable are filled with the "s", "t", "r", and "q" components, respectively, of the vertex texture coordinates for texture unit <n>. If "[n]" is omitted, texture unit zero is used.

If a vertex attribute binding matches "vertex.weight" or "vertex.weight[n]", the "x", "y", "z", and "w" components of the vertex attribute variable are filled with vertex weights <n> through <n>+3, respectively. If "[n]" is omitted, weights zero through three are used. For the purposes of this binding, all weights supported by the implementation but not set by the application are set to zero, including the extra derived weight corresponding to the fixed-function WEIGHT_SUM_UNITY_ARB enable. For components whose corresponding weight is not supported by the implementation (i.e., numbered MAX_VERTEX_UNITS_ARB or larger), "y" and "z" components are set to 0.0 and "w" components are set to 1.0. A vertex program will fail to load if a vertex attribute binding specifies a weight number <n> that is greater than or equal to MAX_VERTEX_UNITS_ARB or is not divisible by four.

If a vertex attribute binding matches "vertex.matrixindex" or "vertex.matrixindex[n]", the "x", "y", "z", and "w" components of the vertex attribute variable are filled with matrix indices <n> through <n>+3 of the vertex, respectively. If "[n]" is omitted, matrix indices zero through three are used. For components whose corresponding matrix index is not supported by the implementation (i.e., numbered MAX_VERTEX_UNITS_ARB or larger), "y", and "z" components are set to 0.0 and "w" components are set to 1.0. A vertex program will fail to load if an attribute binding specifies a matrix index number <n> that is greater than or equal MAX_VERTEX_UNITS_ARB or is not divisible by four.

If a vertex attribute binding matches "vertex.attrib[n]", the "x", "y", "z" and "w" components of the vertex attribute variable are filled with the "x", "y", "z", and "w" components, respectively, of generic vertex attribute <n>. Note that "vertex.attrib[0]" and "vertex.position" are equivalent.

As described in section 2.7, setting a generic vertex attribute may leave a corresponding conventional vertex attribute undefined, and vice versa. To prevent inadvertent use of attribute pairs with undefined attributes, a vertex program will fail to load if it binds both a conventional vertex attribute and a generic vertex attribute listed in the same row of Table X.2.1.

Conventional Attribute Binding	Generic Attribute Binding
vertex.position	vertex.attrib[0]
vertex.weight	vertex.attrib[1]
vertex.weight[0]	vertex.attrib[1]
vertex.normal	vertex.attrib[2]
vertex.color	vertex.attrib[3]
vertex.color.primary	vertex.attrib[3]
vertex.color.secondary	vertex.attrib[4]
vertex.fogcoord	vertex.attrib[5]
vertex.texcoord	vertex.attrib[8]
vertex.texcoord[0]	vertex.attrib[8]
vertex.texcoord[1]	vertex.attrib[9]
vertex.texcoord[2]	vertex.attrib[10]
vertex.texcoord[3]	vertex.attrib[11]
vertex.texcoord[4]	vertex.attrib[12]
vertex.texcoord[5]	vertex.attrib[13]
vertex.texcoord[6]	vertex.attrib[14]
vertex.texcoord[7]	vertex.attrib[15]
vertex.texcoord[n]	vertex.attrib[8+n]

Table X.2.1: Invalid Vertex Attribute Binding Pairs. Vertex programs may not bind both attributes listed in any row. The <n> in the last row matches the number of any valid texture unit.

Section 2.14.3.2, Vertex Program Parameters

Vertex program parameter variables are a set of four-component floating-point vectors used as constants during vertex program execution. Vertex program parameters retain their values across vertex program invocations, although their values can change between invocations due to GL state changes.

Single program parameter variables and arrays of program parameter variables can be declared explicitly using the <PARAM_statement> grammar rule. Single program parameter variables can also be declared implicitly using the <paramSingleItemUse> grammar rule in an executable instruction.

Each single program parameter variable is bound to a constant vector or to a GL state vector according to the <paramSingleInit> grammar rule. Individual items of a program parameter array are bound to constant vectors or GL state vectors according to the <programMultipleInit> grammar rule. The set of GL state that can be bound to program parameter variables are given in Tables X.3.1 through X.3.8.

Constant Bindings

A program parameter variable can be bound to a scalar or vector constant using the <paramConstDecl> grammar rule (explicit declarations) or the <paramConstUse> grammar rule (implicit declarations).

If a program parameter binding matches the <paramConstScalarDecl> or <paramConstScalarUse> grammar rules, the corresponding program parameter variable is bound to the vector (X,X,X,X), where X is the value of the specified constant. Note that the <paramConstScalarUse> grammar rule, used only in implicit declarations, allows only non-negative constants. This disambiguates cases like "-2", which could conceivably be taken to mean either the vector "(2,2,2,2)" with all components negated or "(-2,-2,-2,-2)" without negation. Only the former interpretation is allowed by the grammar.

If a program parameter binding matches <paramConstVector>, the corresponding program parameter variable is bound to the vector (X,Y,Z,W), where X, Y, Z, and W are the values corresponding to the first, second, third, and fourth match of <signedFloatConstant>. If fewer than four constants are specified, Y, Z, and W assume the values 0.0, 0.0, and 1.0, if their respective constants are not specified.

Program parameter variables initialized to constant values can never be modified.

Program Environment/Local Parameter Bindings

Binding	Components	Underlying State
program.env[a]	(x,y,z,w)	program environment parameter a
program.local[a]	(x,y,z,w)	program local parameter a
program.env[a..b]	(x,y,z,w)	program environment parameters a through b
program.local[a..b]	(x,y,z,w)	program local parameters a through b

Table X.3.1: Program Environment/Local Parameter Bindings. <a> and <b> indicate parameter numbers, where <a> must be less than or equal to <b>.

If a program parameter binding matches "program.env[a]" or "program.local[a]", the four components of the program parameter variable are filled with the four components of program environment parameter <a> or program local parameter <a>, respectively.

Additionally, for program parameter array bindings, "program.env[a..b]" and "program.local[a..b]" are equivalent to specifying program environment parameters <a> through <b> in order or program local parameters <a> through <b> in order, respectively. In either case, a program will fail to load if <a> is greater than <b>.

Material Property Bindings

Binding	Components	Underlying State
state.material.ambient	(r,g,b,a)	front ambient material color
state.material.diffuse	(r,g,b,a)	front diffuse material color
state.material.specular	(r,g,b,a)	front specular material color
state.material.emission	(r,g,b,a)	front emissive material color
state.material.shininess	(s,0,0,1)	front material shininess
state.material.front.ambient	(r,g,b,a)	front ambient material color
state.material.front.diffuse	(r,g,b,a)	front diffuse material color
state.material.front.specular	(r,g,b,a)	front specular material color
state.material.front.emission	(r,g,b,a)	front emissive material color
state.material.front.shininess	(s,0,0,1)	front material shininess
state.material.back.ambient	(r,g,b,a)	back ambient material color
state.material.back.diffuse	(r,g,b,a)	back diffuse material color
state.material.back.specular	(r,g,b,a)	back specular material color
state.material.back.emission	(r,g,b,a)	back emissive material color
state.material.back.shininess	(s,0,0,1)	back material shininess

Table X.3.2: Material Property Bindings. If a material face is not specified in the binding, the front property is used.

If a program parameter binding matches any of the material properties listed in Table X.3.2, the program parameter variable is filled according to the table. For ambient, diffuse, specular, or emissive colors, the "x", "y", "z", and "w" components are filled with the "r", "g", "b", and "a" components, respectively, of the corresponding material color. For material shininess, the "x" component is filled with the material's specular exponent, and the "y", "z", and "w" components are filled with 0, 0, and 1, respectively. Bindings containing ".back" refer to the back material; all other bindings refer to the front material.

Material properties can be changed inside a Begin/End pair, either directly by calling Material, or indirectly through color material. However, such property changes are not guaranteed to update program parameter bindings until the following End command. Program parameter variables bound to material properties changed inside a Begin/End pair are undefined until the following End command.

Light Property Bindings

Binding	Components	Underlying State
state.light[n].ambient	(r,g,b,a)	light n ambient color
state.light[n].diffuse	(r,g,b,a)	light n diffuse color
state.light[n].specular	(r,g,b,a)	light n specular color
state.light[n].position	(x,y,z,w)	light n position
state.light[n].attenuation	(a,b,c,e)	light n attenuation constants and spot light exponent
state.light[n].spot.direction	(x,y,z,c)	light n spot direction and cutoff angle cosine
state.light[n].half	(x,y,z,1)	light n infinite half-angle
state.lightmodel.ambient	(r,g,b,a)	light model ambient color
state.lightmodel.scenecolor	(r,g,b,a)	light model front scene color
state.lightmodel . front.scenecolor	(r,g,b,a)	light model front scene color
state.lightmodel . back.scenecolor	(r,g,b,a)	light model back scene color
state.lightprod[n].ambient	(r,g,b,a)	light n / front material ambient color product
state.lightprod[n].diffuse	(r,g,b,a)	light n / front material diffuse color product
state.lightprod[n].specular	(r,g,b,a)	light n / front material specular color product
state.lightprod[n]. front.ambient	(r,g,b,a)	light n / front material ambient color product
state.lightprod[n]. front.diffuse	(r,g,b,a)	light n / front material diffuse color product
state.lightprod[n]. front.specular	(r,g,b,a)	light n / front material specular color product
state.lightprod[n]. back.ambient	(r,g,b,a)	light n / back material ambient color product
state.lightprod[n]. back.diffuse	(r,g,b,a)	light n / back material diffuse color product
state.lightprod[n]. back.specular	(r,g,b,a)	light n / back material specular color product

Table X.3.3: Light Property Bindings. <n> indicates a light number.

If a program parameter binding matches "state.light[n].ambient", "state.light[n].diffuse", or "state.light[n].specular", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "r", "g", "b", and "a" components, respectively, of the corresponding light color.

If a program parameter binding matches "state.light[n].position", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "x", "y", "z", and "w" components, respectively, of the light position.

If a program parameter binding matches "state.light[n].attenuation", the "x", "y", and "z" components of the program parameter variable are filled with the constant, linear, and quadratic attenuation parameters of the specified light, respectively (section 2.13.1). The "w" component of the program parameter variable is filled with the spot light exponent of the specified light.

If a program parameter binding matches "state.light[n].spot.direction", the "x", "y", and "z" components of the program parameter variable are filled with the "x", "y", and "z" components of the spot light direction of the specified light, respectively (section 2.13.1). The "w" component of the program parameter variable is filled with the cosine of the spot light cutoff angle of the specified light.

If a program parameter binding matches "state.light[n].half", the "x", "y", and "z" components of the program parameter variable are filled with the x, y, and z components, respectively, of the normalized infinite half-angle vector

```
  h_inf = || P + (0, 0, 1) ||.
```

The "w" component is filled with 1. In the computation of h_inf, P consists of the x, y, and z coordinates of the normalized vector from the eye position P_e to the eye-space light position P_pli (section 2.13.1). h_inf is defined to correspond to the normalized half-angle vector when using an infinite light (w coordinate of the position is zero) and an infinite viewer (v_bs is FALSE). For local lights or a local viewer, h_inf is well-defined but does not match the normalized half-angle vector, which will vary depending on the vertex position.

If a program parameter binding matches "state.lightmodel.ambient", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "r", "g", "b", and "a" components of the light model ambient color, respectively.

If a program parameter binding matches "state.lightmodel.scenecolor" or "state.lightmodel.front.scenecolor", the "x", "y", and "z" components of the program parameter variable are filled with the "r", "g", and "b" components respectively of the "front scene color"

```
  c_scene = a_cs * a_cm + e_cm,
```

where a_cs is the light model ambient color, a_cm is the front ambient material color, and e_cm is the front emissive material color. The "w" component of the program parameter variable is filled with the alpha component of the front diffuse material color. If a program parameter binding matches "state.lightmodel.back.scenecolor", a similar back scene color, computed using back-facing material properties, is used. The front and back scene colors match the values that would be assigned to vertices using conventional lighting if all lights were disabled.

If a program parameter binding matches anything beginning with "state.lightprod[n]", the "x", "y", and "z" components of the program parameter variable are filled with the "r", "g", and "b" components, respectively, of the corresponding light product. The three light product components are the products of the corresponding color components of the specified material property and the light color of the specified light (see Table X.3.3). The "w" component of the program parameter variable is filled with the alpha component of the specified material property.

Light products depend on material properties, which can be changed inside a Begin/End pair. Such property changes are not guaranteed to take effect until the following End command. Program parameter variables bound to light products whose corresponding material property changes inside a Begin/End pair are undefined until the following End command.

Texture Coordinate Generation Property Bindings

Binding	Components	Underlying State
state.texgen[n].eye.s	(a,b,c,d)	TexGen eye linear plane coefficients, s coord, unit n
state.texgen[n].eye.t	(a,b,c,d)	TexGen eye linear plane coefficients, t coord, unit n
state.texgen[n].eye.r	(a,b,c,d)	TexGen eye linear plane coefficients, r coord, unit n
state.texgen[n].eye.q	(a,b,c,d)	TexGen eye linear plane coefficients, q coord, unit n
state.texgen[n].object.s	(a,b,c,d)	TexGen object linear plane coefficients, s coord, unit n
state.texgen[n].object.t	(a,b,c,d)	TexGen object linear plane coefficients, t coord, unit n
state.texgen[n].object.r	(a,b,c,d)	TexGen object linear plane coefficients, r coord, unit n
state.texgen[n].object.q	(a,b,c,d)	TexGen object linear plane coefficients, q coord, unit n

Table X.3.4: Texture Coordinate Generation Property Bindings. "[n]" is optional -- texture unit <n> is used if specified; texture unit 0 is used otherwise.

If a program parameter binding matches a set of TexGen plane coefficients, the "x", "y", "z", and "w" components of the program parameter variable are filled with the coefficients p1, p2, p3, and p4, respectively, for object linear coefficients, and the coefficents p1', p2', p3', and p4', respectively, for eye linear coefficients (section 2.10.4).

Fog Property Bindings

Binding	Components	Underlying State
state.fog.color	(r,g,b,a)	RGB fog color (section 3.10)
state.fog.params	(d,s,e,r)	fog density, linear start and end, and 1/(end-start) (section 3.10)

Table X.3.5: Fog Property Bindings

If a program parameter binding matches "state.fog.color", the "x", "y", "z", and "w" components of the program parameter variable are filled with the "r", "g", "b", and "a" components, respectively, of the fog color (section 3.10).

If a program parameter binding matches "state.fog.params", the "x", "y", and "z" components of the program parameter variable are filled with the fog density, linear fog start, and linear fog end parameters (section 3.10), respectively. The "w" component is filled with 1/(end-start), where end and start are the linear fog end and start parameters, respectively.

Clip Plane Property Bindings

Binding	Components	Underlying State
state.clip[n].plane	(a,b,c,d)	clip plane n coefficients

Table X.3.6: Clip Plane Property Bindings. <n> specifies the clip plane number, and is required.

If a program parameter binding matches "state.clip[n].plane", the "x", "y", "z", and "w" components of the program parameter variable are filled with the coefficients p1', p2', p3', and p4', respectively, of clip plane <n> (section 2.11).

Point Property Bindings

Binding	Components	Underlying State
state.point.size	(s,n,x,f)	point size, min and max size clamps, and fade threshold (section 3.3)
state.point.attenuation	(a,b,c,1)	point size attenuation consts

Table X.3.7: Point Property Bindings

If a program parameter binding matches "state.point.size", the "x", "y", "z", and "w" components of the program parameter variable are filled with the point size, minimum point size, maximum point size, and fade threshold, respectively (section 3.3).

If a program parameter binding matches "state.point.attenuation", the "x", "y", and "z" components of the program parameter variable are filled with the constant, linear, and quadratic point size attenuation parameters (a, b, and c), respectively (section 3.3). The "w" component is filled with 1.

Matrix Property Bindings

Binding	Underlying State
* state.matrix.modelview[n]	modelview matrix n
state.matrix.projection	projection matrix
state.matrix.mvp	modelview-projection matrix
* state.matrix.texture[n]	texture matrix n
state.matrix.palette[n]	modelview palette matrix n
state.matrix.program[n]	program matrix n

Table X.3.8: Base Matrix Property Bindings. The "[n]" syntax indicates a specific matrix number. For modelview and texture matrices, a matrix number is optional, and matrix zero will be used if the matrix number is omitted. These base bindings may further be modified by a inverse/transpose selector and a row selector.

If the beginning of a program parameter binding matches any of the matrix binding names listed in Table X.3.8, the binding corresponds to a 4x4 matrix. If the parameter binding is followed by ".inverse", ".transpose", or ".invtrans" (<stateMatModifier> grammar rule), the inverse, transpose, or transpose of the inverse, respectively, of the matrix specified in Table X.3.8 is selected. Otherwise, the matrix specified in Table X.3.8 is selected. If the specified matrix is poorly-conditioned (singular or nearly so), its inverse matrix is undefined. The binding name "state.matrix.mvp" refers to the product of modelview matrix zero and the projection matrix, defined as

```
   MVP = P * M0,
```

where P is the projection matrix and M0 is modelview matrix zero.

If the selected matrix is followed by ".row[<a>]" (matching the <stateMatrixRow> grammar rule), the "x", "y", "z", and "w" components of the program parameter variable are filled with the four entries of row <a> of the selected matrix. In the example,

```
  PARAM m0 = state.matrix.modelview[1].row[0];
  PARAM m1 = state.matrix.projection.transpose.row[3];
```

the variable "m0" is set to the first row (row 0) of modelview matrix 1 and "m1" is set to the last row (row 3) of the transpose of the projection matrix.

For program parameter array bindings, multiple rows of the selected matrix can be bound via the <stateMatrixRows> grammar rule. If the selected matrix binding is followed by ".row[<a>..<b>]", the result is equivalent to specifying matrix rows <a> through <b>, in order. A program will fail to load if <a> is greater than <b>. If no row selection is specified (<optMatrixRows> matches ""), matrix rows 0 through 3 are bound in order. In the example,

```
  PARAM m2[] = { state.matrix.program[0].row[1..2] };
  PARAM m3[] = { state.matrix.program[0].transpose };
```

the array "m2" has two entries, containing rows 1 and 2 of program matrix zero, and "m3" has four entries, containing all four rows of the transpose of program matrix zero.

Program Parameter Arrays

A program parameter array variable can be declared explicitly by matching the <PARAM_multipleStmt> grammar rule. Programs can optionally specify the number of individual program parameters in the array, using the <optArraySize> grammar rule. Program parameter arrays may not be declared implicity.

Individual parameter variables in a program parameter array are bound to GL state vectors or constant vectors as specified by the grammar rule <paramMultInitList>. Each individual parameter in the array is bound in turn as described above.

The total number of entries in the array is equal to the number of parameters bound in the initializer list. A vertex program that specifies an array size (<optArraySize> matches <integer>) that does not match the number of parameter bindings in the initialization list will fail to load.

Program parameter array variables may be accessed using absolute addressing by matching the <progParamArrayAbs> grammar rule, or relative addressing by matching the <progParamArrayRel> grammar rule.

Array accesses using absolute addressing are checked against the limits of the array. If any vertex program instruction accesses a program parameter array using absolute addressing with an out-of-range index (greater than or equal to the size of the array), the vertex program will fail to load.

Individual state vectors can have no more than one unique binding in any given program. The GL will automatically combine multiple bindings of the same state vector into a single unique binding, except for the case where a state vector is bound multiple times in program parameter arrays accessed using relative addressing. A vertex program will fail to load if any GL state vector is bound multiple times in a single array accessed using relative addressing or bound once in two or more arrays accessed using relative addressing.

Section 2.14.3.3, Vertex Program Temporaries

Vertex program temporary variables are a set of four-component floating-point vectors used to hold temporary results during vertex program execution. Temporaries do not persist between program invocations, and are undefined at the beginning of each vertex program invocation.

Vertex program temporary variables can be declared explicitly using the <TEMP_statement> grammar rule. Each such statement can declare one or more temporaries. Vertex program temporary variables can not be declared implicitly.

Section 2.14.3.4, Vertex Program Results

Vertex program result variables are a set of four-component floating-point vectors used to hold the final results of a vertex program. Vertex program result variables are write-only during vertex program execution.

Vertex program result variables can be declared explicitly using the <OUTPUT_statement> grammar rule, or implicitly using the <resultBinding> grammar rule in an executable instruction. Each vertex program result variable is bound to a transformed vertex attribute used during primitive assembly and rasterization. The set of vertex program result variable bindings is given in Table X.4.

Binding	Components	Description
result.position	(x,y,z,w)	position in clip coordinates
result.color	(r,g,b,a)	front-facing primary color
result.color.primary	(r,g,b,a)	front-facing primary color
result.color.secondary	(r,g,b,a)	front-facing secondary color
result.color.front	(r,g,b,a)	front-facing primary color
result.color.front.primary	(r,g,b,a)	front-facing primary color
result.color.front.secondary	(r,g,b,a)	front-facing secondary color
result.color.back	(r,g,b,a)	back-facing primary color
result.color.back.primary	(r,g,b,a)	back-facing primary color
result.color.back.secondary	(r,g,b,a)	back-facing secondary color
result.fogcoord	(f,*,*,*)	fog coordinate
result.pointsize	(s,*,*,*)	point size
result.texcoord	(s,t,r,q)	texture coordinate, unit 0
result.texcoord[n]	(s,t,r,q)	texture coordinate, unit n

Table X.4: Vertex Result Variable Bindings. Components labeled "*" are unused.

If a result variable binding matches "result.position", updates to the "x", "y", "z", and "w" components of the result variable modify the "x", "y", "z", and "w" components, respectively, of the transformed vertex's clip coordinates. Final window coordinates will be generated for the vertex as described in section 2.14.4.4.

If a result variable binding match begins with "result.color", updates to the "x", "y", "z", and "w" components of the result variable modify the "r", "g", "b", and "a" components, respectively, of the corresponding vertex color attribute in Table X.4. Color bindings that do not specify "front" or "back" are consided to refer to front-facing colors. Color bindings that do not specify "primary" or "secondary" are considered to refer to primary colors.

If a result variable binding matches "result.fogcoord", updates to the "x" component of the result variable set the transformed vertex's fog coordinate. Updates to the "y", "z", and "w" components of the result variable have no effect.

If a result variable binding matches "result.pointsize", updates to the "x" component of the result variable set the transformed vertex's point size. Updates to the "y", "z", and "w" components of the result variable have no effect.

If a result variable binding matches "result.texcoord" or "result.texcoord[n]", updates to the "x", "y", "z", and "w" components of the result variable set the "s", "t", "r" and "q" components, respectively, of the transformed vertex's texture coordinates for texture unit <n>. If "[n]" is omitted, texture unit zero is selected.

When in vertex program mode, all attributes of a transformed vertex are undefined at each vertex program invocation. Any results, or even individual components of results, that are not written to during vertex program execution remain undefined.

Section 2.14.3.5, Vertex Program Address Registers

Vertex program address register variables are a set of four-component signed integer vectors where only the "x" component of the address registers is currently accessible. Address registers are used as indices when performing relative addressing in program parameter arrays (section 2.14.4.2).

Vertex program address registers can be declared explicitly using the <ADDRESS_statement> grammar rule. Each such statement can declare one or more address registers. Vertex program address registers can not be declared implicitly.

Vertex program address register variables are undefined at each vertex program invocation. Address registers can be written by the ARL instruction (section 2.14.5.3), and will be read when a program uses relative addressing in program parameter arrays.

Section 2.14.3.6, Vertex Program Aliases

Vertex programs can create aliases by matching the <ALIAS_statement> grammar rule. Aliases allow programs to use multiple variable names to refer to a single underlying variable. For example, the statement

```
  ALIAS var1 = var0
```

establishes a variable name named "var1". Subsequent references to "var1" in the program text are treated as references to "var0". The left hand side of an ALIAS statement must be a new variable name, and the right hand side must be an established variable name.

Aliases are not considered variable declarations, so do not count against the limits on the number of variable declarations allowed in the program text.

Section 2.14.3.7, Vertex Program Resource Limits

The vertex program execution environment provides implementation-dependent resource limits on the number of instructions, temporary variable declarations, vertex attribute bindings, address register declarations, and program parameter bindings. A program that exceeds any of these resource limits will fail to load. The resource limits for vertex programs can be queried by calling GetProgramiv (section 6.1.12) with a target of VERTEX_PROGRAM_ARB.

The limit on vertex program instructions can be queried with a <pname> of MAX_PROGRAM_INSTRUCTIONS_ARB, and must be at least 128. Each instruction in the program (matching the <instruction> grammar rule) counts against this limit.

The limit on vertex program temporary variable declarations can be queried with a <pname> of MAX_PROGRAM_TEMPORARIES_ARB, and must be at least 12. Each temporary declared in the program, using the <TEMP_statement> grammar rule, counts against this limit. Aliases of declared temporaries do not.

The limit on vertex program attribute bindings can be queried with a <pname> of MAX_PROGRAM_ATTRIBS_ARB and must be at least 16. Each distinct vertex attribute bound explicitly or implicitly in the program counts against this limit; vertex attributes bound multiple times count only once.

The limit on vertex program address register declarations can be queried with a <pname> of MAX_PROGRAM_ADDRESS_REGISTERS_ARB, and must be at least 1. Each address register declared in the program, using the <ADDRESS_statement> grammar rule, counts against this limit.

The limit on vertex program parameter bindings can be queried with a <pname> of MAX_PROGRAM_PARAMETERS_ARB, and must be at least 96. Each distinct GL state vector bound explicitly or implicitly in the program counts against this limit; GL state vectors bound multiple times count only once. Each constant vector bound to an array accessed using relative addressing counts against this limit, even if the same constant vector is bound multiple times or in multiple arrays. Every other constant vector bound in the program is counted if and only if an identical constant vector has not already been counted. Two constant vectors are considered identical if the four component values are numerically equivalent. Recall that scalar constants bound in a program are treated as vector constants with the scalar value replicated. In the following code

```
    PARAM arr1[4] = { {1,2,3,4}, {1,2,3,4}, {4,4,4,4}, {5,6,7,8} };
    PARAM arr2[3] = { {1,2,3,4}, {5,6,7,8}, {0,1,2,3} };
    PARAM x = {4,3,2,1};
    PARAM y = {1,2,3,4};
    PARAM z = 4;
    PARAM r = {4,3,2,1};
```

assume that arr1 is accessed using relative addressing but arr2 is not. The four constants in arr1 all count against the limit. Only two other constants, {0,1,2,3} in arr2, and {4,3,2,1} in x, are counted; the other constants are identical to constants that had been previously counted.

In addition to the limits described above, the GL provides a similar set of implementation-dependent native resource limits. These limits, specified in section 6.1.12, provide guidance as to whether the program is small enough to use a "native" mode where vertex programs may be executed with higher performance. The native resource limits and usage counts are implementation-dependent and may not exactly correspond to limits and counts described above. In particular, native resource consumption may be reduced by program optimizations performed by the GL, or increased due to emulation of non-native instructions. Programs that satisfy the program resource limits described above, but whose native resource usage exceeds one or more native resource limits, are guaranteed to load but may execute suboptimally.

To assist in resource counting, the GL additionally provides GetProgram queries to determine the resource usage and native resource usage of the currently bound program, and to determine whether the bound program exceeds any native resource limit.

Section 2.14.4, Vertex Program Execution Environment

If vertex program mode is enabled, the currently bound vertex program is executed when a vertex is specified directly through the Vertex command, indirectly through vertex arrays or evaluators (section 5.1), or when the current raster position is updated.

If vertex program mode is enabled and the currently bound program object does not contain a valid vertex program, the error INVALID_OPERATION will be generated by Begin, RasterPos, and any command that implicitly calls Begin (e.g., DrawArrays).

Vertex programs execute a sequence of instructions without branching. Vertex programs begin by executing the first instruction in the program, and execute instructions in the order specified in the program until the last instruction is completed.

There are twenty-seven vertex program instructions. The instructions and their respective input and output parameters are summarized in Table X.5.

Instruction	Inputs	Output	Description
ABS	v	v	absolute value
ADD	v,v	v	add
ARL	s	a	address register load
DP3	v,v	ssss	3-component dot product
DP4	v,v	ssss	4-component dot product
DPH	v,v	ssss	homogeneous dot product
DST	v,v	v	distance vector
EX2	s	ssss	exponential base 2
EXP	s	v	exponential base 2 (approximate)
FLR	v	v	floor
FRC	v	v	fraction
LG2	s	ssss	logarithm base 2
LIT	v	v	compute light coefficients
LOG	s	v	logarithm base 2 (approximate)
MAD	v,v,v	v	multiply and add
MAX	v,v	v	maximum
MIN	v,v	v	minimum
MOV	v	v	move
MUL	v,v	v	multiply
POW	s,s	ssss	exponentiate
RCP	s	ssss	reciprocal
RSQ	s	ssss	reciprocal square root
SGE	v,v	v	set on greater than or equal
SLT	v,v	v	set on less than
SUB	v,v	v	subtract
SWZ	v	v	extended swizzle
XPD	v,v	v	cross product

Table X.5: Summary of vertex program instructions. "v" indicates a floating-point vector input or output, "s" indicates a floating-point scalar input, "ssss" indicates a scalar output replicated across a 4-component result vector, and "a" indicates a single address register component.

Section 2.14.4.1, Vertex Program Operands

Most vertex program instructions operate on floating-point vectors or scalars, as indicated by the grammar rules <swizzleSrcReg> and <scalarSrcReg>, respectively.

Vector and scalar operands can be obtained from vertex attribute, program parameter, or temporary registers, as indicated by the <srcReg> rule. For scalar operands, a single vector component is selected by the <scalarSuffix> rule, where the characters "x", "y", "z", and "w" select the x, y, z, and w components, respectively, of the vector.

Vector operands can be swizzled according to the <swizzleSuffix> rule. In its most general form, the <swizzleSuffix> rule matches the pattern ".????" where each question mark is replaced with one of "x", "y", "z", or "w". For such patterns, the x, y, z, and w components of the operand are taken from the vector components named by the first, second, third, and fourth character of the pattern, respectively. For example, if the swizzle suffix is ".yzzx" and the specified source contains {2,8,9,0}, the swizzled operand used by the instruction is {8,9,9,2}.

If the <swizzleSuffix> rule matches "", it is treated as though it were ".xyzw". If the <swizzleSuffix> rule matches (ignoring whitespace) ".x", ".y", ".z", or ".w", these are treated the same as ".xxxx", ".yyyy", ".zzzz", and ".wwww" respectively.

Floating-point scalar or vector operands can optionally be negated according to the <optionalSign> rule in <scalarSrcReg> and <swizzleSrcReg>. If the <optionalSign> matches "-", each operand or operand component is negated.

The following pseudo-code spells out the operand generation process. In the example, "float" is a floating-point scalar type, while "floatVec" is a four-component vector. "source" refers to the register used for the operand, matching the <srcReg> rule. "negate" is TRUE if the <optionalSign> rule in <scalarSrcReg> or <swizzleSrcReg> matches "-" and FALSE otherwise. The ".c***", ".*c**", ".**c*", ".***c" modifiers refer to the x, y, z, and w components obtained by the swizzle operation; the ".c" modifier refers to the single component selected for a scalar load.

```
  floatVec VectorLoad(floatVec source)
  {
      floatVec operand;

      operand.x = source.c***;
      operand.y = source.*c**;
      operand.z = source.**c*;
      operand.w = source.***c;
      if (negate) {
         operand.x = -operand.x;
         operand.y = -operand.y;
         operand.z = -operand.z;
         operand.w = -operand.w;
      }

      return operand;
  }
  float ScalarLoad(floatVec source)
  {
      float operand;

      operand = source.c;
      if (negate) {
        operand = -operand;
      }

      return operand;
  }
```

Section 2.14.4.2, Vertex Program Parameter Arrays

A vertex program can load a single element of a program parameter array using either absolute or relative addressing. Program parameter arrays are accessed when the <progParamArray> rule is matched.

Absolute addressing is used when the <progParamArrayMem> grammar rule matches <progParamArrayAbs>. When using absolute addressing, the offset of the selected entry in the array is given by the number matching <progParamRegNum>.

Relative addressing is used when the <progParamArrayMem> grammar rule matches <progParamArrayRel>. When using relative addressing, the offset of the selected entry in the array is computed by adding the address register component specified by the <addrReg> and <addrComponent> rules to the positive or negative offset specified by the <addrRegRelOffset> rule. If <addrRegRelOffset> matches "", no fixed offset is added to the address register component. If the computed offset is negative or exceeds the size of the array, the results of the access are undefined, but may not lead to program or GL termination.

The following pseudo-code spells out the process of loading a program parameter from an array. "addrReg" refers to the address register component used for relative addressing, "absolute" is TRUE if the operand uses absolute addressing and FALSE otherwise. "paramNumber" is the program parameter number for absolute addressing; "paramOffset" is the constant program parameter offset for relative addressing. "paramArray" is the parameter array that matches the <progParamArray> rule.

```
  floatVec ProgramParameterLoad(int addrReg)
  {
    int index;

    if (absolute) {
      index = paramNumber;
    } else {
      index = addrReg + paramOffset
    }

    return paramArray[index];
  }
```

Relative addressing can only be used for accessing program parameter arrays.

Section 2.14.4.3, Vertex Program Destination Register Update

Most vertex program instructions write a 4-component result vector to a single temporary or vertex result register. Writes to individual components of the destination register are controlled by individual component write masks specified as part of the instruction.

The component write mask is specified by the <optionalMask> rule found in the <maskedDstReg> rule. If the optional mask is "", all components are enabled. Otherwise, the optional mask names the individual components to enable. The characters "x", "y", "z", and "w" match the x, y, z, and w components respectively. For example, an optional mask of ".xzw" indicates that the x, z, and w components should be enabled for writing but the y component should not. The grammar requires that the destination register mask components must be listed in "xyzw" order.

Each component of the destination register is updated with the result of the vertex program instruction if and only if the component is enabled for writes by the component write mask. Otherwise, the component of the destination register remains unchanged.

The following pseudocode illustrates the process of writing a result vector to the destination register. In the pseudocode, "instrmask" refers to the component write mask given by the <optionalMask> rule. "result" and "destination" refer to the result vector and the register selected by <dstReg>, respectively.

```
  void UpdateDestination(floatVec destination, floatVec result)
  {
      floatVec merged;

      // Merge the converted result into the destination register, under
      // control of the compile-time write mask.
      merged = destination;
      if (instrMask.x) {
          merged.x = result.x;
      }
      if (instrMask.y) {
          merged.y = result.y;
      }
      if (instrMask.z) {
          merged.z = result.z;
      }
      if (instrMask.w) {
          merged.w = result.w;
      }

      // Write out the new destination register.
      destination = merged;
  }
```

The "ARL" instruction updates the single address register component similarly; the grammar is designed so that it writes to only the "x" component of an address register variable.

Section 2.14.4.4, Vertex Program Result Processing

As a vertex program executes, it will write to one or more result registers that are mapped to transformed vertex attributes. When a vertex program completes, the transformed vertex attributes are used to generate primitives.

The clip coordinates written to "result.position" are used to generate normalized device coordinates and window coordinates for the vertex in the manner described section 2.10.

Transformed vertices are then assembled into primitives and clipped as described in section 2.11.

The selection between front-facing and back-facing color attributes depends on the primitive to which the vertex belongs. If the primitive is a point or a line segment, or if vertex program two-sided color mode is disabled, the front-facing colors are always selected. If it is a polygon and two-sided color mode is enabled, then the selection is performed in exactly the same way as in two-sided lighting mode (section 2.13.1). Vertex program two-sided color mode is enabled and disabled by calling Enable or Disable with the symbolic value VERTEX_PROGRAM_TWO_SIDE_ARB.

Finally, as primitives are assembled, color clamping (section 2.13.6), flatshading (section 2.13.7), color, attribute clipping (section 2.13.8), and final color processing (section 2.13.9) operations are applied to the transformed vertices.

Section 2.14.4.5, Vertex Program Options

The <optionSequence> grammar rule provides a mechanism for programs to indicate that one or more extended language features are used by the program. All program options used by the program must be declared at the beginning of the program string. Each program option specified in a program string will modify the syntactic or semantic rules used to interpet the program and the execution environment used to execute the program. Program options not present in the program string are ignored, even if they are supported by the GL.

The <identifier> token in the <option> rule must match the name of a program option supported by the implementation. To avoid option name conflicts, option identifiers are required to begin with a vendor prefix. A program will fail to load if it specifies a program option not supported by the GL.

Vertex program options should confine their semantic changes to the domain of vertex programs. Support for a vertex program option should not change the specification and behavior of vertex programs not requesting use of that option.

2.14.4.5.1, Position-Invariant Vertex Program Option

If a vertex program specifies the "ARB_position_invariant" option, the program is used to generate all transformed vertex attributes except for position. Instead, clip coordinates are computed as specified in section 2.10. Additionally, user clipping is performed as described in section 2.11. Use of position-invariant vertex programs should generally guarantee that the transformed position of a vertex should be the same whether vertex program mode is enabled or disabled, allowing for correct mixed multi-pass rendering semantics.

When the position-invariant option is specified in a vertex program, vertex programs can no longer produced a transformed position. The <resultBinding> rule is modified to remove "result.position" from the list of token sequences matching the rule. A semantic restriction is added to indicate that a vertex program will fail to load if the number of instructions it contains exceeds the implementation-dependent limit minus four.

Section 2.14.5, Vertex Program Instruction Set

The following sections describe the set of supported vertex program instructions. Each section contains pseudocode describing the instruction. Instructions will have up to three operands, referred to as "op0", "op1", and "op2". The operands are loaded using the mechanisms specified in section 2.14.4.1. The variables "tmp", "tmp0", "tmp1", and "tmp2" describe scalars or vectors used to hold intermediate results in the instruction. Most instructions will generate a result vector called "result". The result vector is then written to the destination register specified in the instruction as described in section 2.14.4.3.

Section 2.14.5.1, ABS: Absolute Value

The ABS instruction performs a component-wise absolute value operation on the single operand to yield a result vector.

```
tmp = VectorLoad(op0);
result.x = fabs(tmp.x);
result.y = fabs(tmp.y);
result.z = fabs(tmp.z);
result.w = fabs(tmp.w);
```

Section 2.14.5.2, ADD: Add

The ADD instruction performs a component-wise add of the two operands to yield a result vector.

```
tmp0 = VectorLoad(op0);
tmp1 = VectorLoad(op1);
result.x = tmp0.x + tmp1.x;
result.y = tmp0.y + tmp1.y;
result.z = tmp0.z + tmp1.z;
result.w = tmp0.w + tmp1.w;
```

The following rules apply to addition:

1. <x> + <y> == <y> + <x>, for all <x> and <y>.
2. <x> + 0.0 == <x>, for all <x>.

Section 2.14.5.3, ARL: Address Register Load

The ARL instruction loads a single scalar operand and performs a floor operation to generate a signed integer scalar result:

```
    result = floor(ScalarLoad(op0));
```

The floor operation returns the largest integer less than or equal to the operand. For example floor(-1.7) = -2.0, floor(+1.0) = +1.0, and floor(+3.7) = +3.0.

Section 2.14.5.4, DP3: Three-Component Dot Product

The DP3 instruction computes a three-component dot product of the two operands (using the x, y, and z components) and replicates the dot product to all four components of the result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  dot = (tmp0.x * tmp1.x) + (tmp0.y * tmp1.y) +
        (tmp0.z * tmp1.z);
  result.x = dot;
  result.y = dot;
  result.z = dot;
  result.w = dot;
```

Section 2.14.5.5, DP4: Four-Component Dot Product

The DP4 instruction computes a four-component dot product of the two operands and replicates the dot product to all four components of the result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1):
  dot = (tmp0.x * tmp1.x) + (tmp0.y * tmp1.y) +
        (tmp0.z * tmp1.z) + (tmp0.w * tmp1.w);
  result.x = dot;
  result.y = dot;
  result.z = dot;
  result.w = dot;
```

Section 2.14.5.6, DPH: Homogeneous Dot Product

The DPH instruction computes a three-component dot product of the two operands (using the x, y, and z components), adds the w component of the second operand, and replicates the sum to all four components of the result vector. This is equivalent to a four-component dot product where the w component of the first operand is forced to 1.0.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1):
  dot = (tmp0.x * tmp1.x) + (tmp0.y * tmp1.y) +
        (tmp0.z * tmp1.z) + tmp1.w;
  result.x = dot;
  result.y = dot;
  result.z = dot;
  result.w = dot;
```

Section 2.14.5.7, DST: Distance Vector

The DST instruction computes a distance vector from two specially-formatted operands. The first operand should be of the form [NA, d^2, d^2, NA] and the second operand should be of the form [NA, 1/d, NA, 1/d], where NA values are not relevant to the calculation and d is a vector length. If both vectors satisfy these conditions, the result vector will be of the form [1.0, d, d^2, 1/d].

The exact behavior is specified in the following pseudo-code:

```
tmp0 = VectorLoad(op0);
tmp1 = VectorLoad(op1);
result.x = 1.0;
result.y = tmp0.y * tmp1.y;
result.z = tmp0.z;
result.w = tmp1.w;
```

Given an arbitrary vector, d^2 can be obtained using the DP3 instruction (using the same vector for both operands) and 1/d can be obtained from d^2 using the RSQ instruction.

This distance vector is useful for per-vertex light attenuation calculations: a DP3 operation using the distance vector and an attenuation constants vector as operands will yield the attenuation factor.

Section 2.14.5.8, EX2: Exponential Base 2

The EX2 instruction approximates 2 raised to the power of the scalar operand and replicates the approximation to all four components of the result vector.

```
tmp = ScalarLoad(op0);
result.x = Approx2ToX(tmp);
result.y = Approx2ToX(tmp);
result.z = Approx2ToX(tmp);
result.w = Approx2ToX(tmp);
```

Section 2.14.5.9, EXP: Exponential Base 2 (approximate)

The EXP instruction computes a rough approximation of 2 raised to the power of the scalar operand. The approximation is returned in the "z" component of the result vector. A vertex program can also use the "x" and "y" components of the result vector to generate a more accurate approximation by evaluating

```
    result.x * f(result.y),
```

where f(x) is a user-defined function that approximates 2^x over the domain [0.0, 1.0). The "w" component of the result vector is always 1.0.

The exact behavior is specified in the following pseudo-code:

```
  tmp = ScalarLoad(op0);
  result.x = 2^floor(tmp);
  result.y = tmp - floor(tmp);
  result.z = RoughApprox2ToX(tmp);
  result.w = 1.0;
```

The approximation function is accurate to at least 10 bits:

```
  | RoughApprox2ToX(x) - 2^x | < 1.0 / 2^11, if 0.0 <= x < 1.0,
```

and, in general,

```
  | RoughApprox2ToX(x) - 2^x | < (1.0 / 2^11) * (2^floor(x)).
```

Section 2.14.5.10, FLR: Floor

The FLR instruction performs a component-wise floor operation on the operand to generate a result vector. The floor of a value is defined as the largest integer less than or equal to the value. The floor of 2.3 is 2.0; the floor of -3.6 is -4.0.

```
  tmp = VectorLoad(op0);
  result.x = floor(tmp.x);
  result.y = floor(tmp.y);
  result.z = floor(tmp.z);
  result.w = floor(tmp.w);
```

Section 2.14.5.11, FRC: Fraction

The FRC instruction extracts the fractional portion of each component of the operand to generate a result vector. The fractional portion of a component is defined as the result after subtracting off the floor of the component (see FLR), and is always in the range [0.0, 1.0).

For negative values, the fractional portion is NOT the number written to the right of the decimal point -- the fractional portion of -1.7 is not 0.7 -- it is 0.3. 0.3 is produced by subtracting the floor of -1.7 (-2.0) from -1.7.

```
  tmp = VectorLoad(op0);
  result.x = fraction(tmp.x);
  result.y = fraction(tmp.y);
  result.z = fraction(tmp.z);
  result.w = fraction(tmp.w);
```

Section 2.14.5.12, LG2: Logarithm Base 2

The LG2 instruction approximates the base 2 logarithm of the scalar operand and replicates it to all four components of the result vector.

```
  tmp = ScalarLoad(op0);
  result.x = ApproxLog2(tmp);
  result.y = ApproxLog2(tmp);
  result.z = ApproxLog2(tmp);
  result.w = ApproxLog2(tmp);
```

If the scalar operand is zero or negative, the result is undefined.

Section 2.14.5.13, LIT: Light Coefficients

The LIT instruction accelerates per-vertex lighting by computing lighting coefficients for ambient, diffuse, and specular light contributions. The "x" component of the single operand is assumed to hold a diffuse dot product (n dot VP_pli, as in the vertex lighting equations in Section 2.13.1). The "y" component of the operand is assumed to hold a specular dot product (n dot h_i). The "w" component of the operand is assumed to hold the specular exponent of the material (s_rm), and is clamped to the range (-128, +128) exclusive.

The "x" component of the result vector receives the value that should be multiplied by the ambient light/material product (always 1.0). The "y" component of the result vector receives the value that should be multiplied by the diffuse light/material product (n dot VP_pli). The "z" component of the result vector receives the value that should be multiplied by the specular light/material product (f_i * (n dot h_i) ^ s_rm). The "w" component of the result is the constant 1.0.

Negative diffuse and specular dot products are clamped to 0.0, as is done in the standard per-vertex lighting operations. In addition, if the diffuse dot product is zero or negative, the specular coefficient is forced to zero.

```
  tmp = VectorLoad(op0);
  if (tmp.x < 0) tmp.x = 0;
  if (tmp.y < 0) tmp.y = 0;
  if (tmp.w < -(128.0-epsilon)) tmp.w = -(128.0-epsilon);
  else if (tmp.w > 128-epsilon) tmp.w = 128-epsilon;
  result.x = 1.0;
  result.y = tmp.x;
  result.z = (tmp.x > 0) ? RoughApproxPower(tmp.y, tmp.w) : 0.0;
  result.w = 1.0;
```

The exponentiation approximation function may be defined in terms of the base 2 exponentiation and logarithm approximation operations in the EXP and LOG instructions, where

```
  RoughApproxPower(a,b) = RoughApproxExp2(b * RoughApproxLog2(a)).
```

In particular, the approximation may not be any more accurate than the underlying EXP and LOG operations.

Also, since 0^0 is defined to be 1, RoughApproxPower(0.0, 0.0) will produce 1.0.

Section 2.14.5.14, LOG: Logarithm Base 2 (approximate)

The LOG instruction computes a rough approximation of the base 2 logarithm of the absolute value of the scalar operand. The approximation is returned in the "z" component of the result vector. A vertex program can also use the "x" and "y" components of the result vector to generate a more accurate approximation by evaluating

```
result.x + f(result.y),
```

where f(x) is a user-defined function that approximates 2^x over the domain [1.0, 2.0). The "w" component of the result vector is always 1.0.

The exact behavior is specified in the following pseudo-code:

```
tmp = fabs(ScalarLoad(op0));
result.x = floor(log2(tmp));
result.y = tmp / 2^(floor(log2(tmp)));
result.z = RoughApproxLog2(tmp);
result.w = 1.0;
```

Here, "floor(log2(tmp))" refers to the floor of the exact logarithm, which can be easily computed for standard floating-point representations. The approximation function is accurate to at least 10 bits:

```
| RoughApproxLog2(x) - log_2(x) | < 1.0 / 2^11.
```

Section 2.14.5.15, MAD: Multiply and Add

The MAD instruction performs a component-wise multiply of the first two operands, and then does a component-wise add of the product to the third operand to yield a result vector.

```
tmp0 = VectorLoad(op0);
tmp1 = VectorLoad(op1);
tmp2 = VectorLoad(op2);
result.x = tmp0.x * tmp1.x + tmp2.x;
result.y = tmp0.y * tmp1.y + tmp2.y;
result.z = tmp0.z * tmp1.z + tmp2.z;
result.w = tmp0.w * tmp1.w + tmp2.w;
```

The multiplication and addition operations in this instruction are subject to the same rules as described for the MUL and ADD instructions.

Section 2.14.5.16, MAX: Maximum

The MAX instruction computes component-wise maximums of the values in the two operands to yield a result vector.

```
tmp0 = VectorLoad(op0);
tmp1 = VectorLoad(op1);
result.x = (tmp0.x > tmp1.x) ? tmp0.x : tmp1.x;
result.y = (tmp0.y > tmp1.y) ? tmp0.y : tmp1.y;
result.z = (tmp0.z > tmp1.z) ? tmp0.z : tmp1.z;
result.w = (tmp0.w > tmp1.w) ? tmp0.w : tmp1.w;
```

Section 2.14.5.17, MIN: Minimum

The MIN instruction computes component-wise minimums of the values in the two operands to yield a result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = (tmp0.x > tmp1.x) ? tmp1.x : tmp0.x;
  result.y = (tmp0.y > tmp1.y) ? tmp1.y : tmp0.y;
  result.z = (tmp0.z > tmp1.z) ? tmp1.z : tmp0.z;
  result.w = (tmp0.w > tmp1.w) ? tmp1.w : tmp0.w;
```

Section 2.14.5.18, MOV: Move

The MOV instruction copies the value of the operand to yield a result vector.

```
  result = VectorLoad(op0);
```

Section 2.14.5.19, MUL: Multiply

The MUL instruction performs a component-wise multiply of the two operands to yield a result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = tmp0.x * tmp1.x;
  result.y = tmp0.y * tmp1.y;
  result.z = tmp0.z * tmp1.z;
  result.w = tmp0.w * tmp1.w;
```

The following rules apply to multiplication:

1. <x> * <y> == <y> * <x>, for all <x> and <y>.
2. +/-0.0 * <x> = +/-0.0, at least for all <x> that correspond to representable numbers (IEEE "not a number" and "infinity" encodings may be exceptions).
3. +1.0 * <x> = <x>, for all <x>.

Multiplication by zero and one should be invariant, as it may be used to evaluate conditional expressions without branching.

Section 2.14.5.20, POW: Exponentiate

The POW instruction approximates the value of the first scalar operand raised to the power of the second scalar operand and replicates it to all four components of the result vector.

```
  tmp0 = ScalarLoad(op0);
  tmp1 = ScalarLoad(op1);
  result.x = ApproxPower(tmp0, tmp1);
  result.y = ApproxPower(tmp0, tmp1);
  result.z = ApproxPower(tmp0, tmp1);
  result.w = ApproxPower(tmp0, tmp1);
```

The exponentiation approximation function may be implemented using the base 2 exponentiation and logarithm approximation operations in the EX2 and LG2 instructions. In particular,

```
  ApproxPower(a,b) = ApproxExp2(b * ApproxLog2(a)).
```

Note that a logarithm may be involved even for cases where the exponent is an integer. This means that it may not be possible to exponentiate correctly with a negative base. In constrast, it is possible in a "normal" mathematical formulation to raise negative numbers to integral powers (e.g., (-3)^2== 9, and (-0.5)^-2==4).

Section 2.14.5.21, RCP: Reciprocal

The RCP instruction approximates the reciprocal of the scalar operand and replicates it to all four components of the result vector.

```
  tmp = ScalarLoad(op0);
  result.x = ApproxReciprocal(tmp);
  result.y = ApproxReciprocal(tmp);
  result.z = ApproxReciprocal(tmp);
  result.w = ApproxReciprocal(tmp);
```

The following rule applies to reciprocation:

1. ApproxReciprocal(+1.0) = +1.0.

Section 2.14.5.22, RSQ: Reciprocal Square Root

The RSQ instruction approximates the reciprocal of the square root of the absolute value of the scalar operand and replicates it to all four components of the result vector.

```
  tmp = fabs(ScalarLoad(op0));
  result.x = ApproxRSQRT(tmp);
  result.y = ApproxRSQRT(tmp);
  result.z = ApproxRSQRT(tmp);
  result.w = ApproxRSQRT(tmp);
```

Section 2.14.5.23, SGE: Set On Greater or Equal Than

The SGE instruction performs a component-wise comparison of the two operands. Each component of the result vector is 1.0 if the corresponding component of the first operands is greater than or equal that of the second, and 0.0 otherwise.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = (tmp0.x >= tmp1.x) ? 1.0 : 0.0;
  result.y = (tmp0.y >= tmp1.y) ? 1.0 : 0.0;
  result.z = (tmp0.z >= tmp1.z) ? 1.0 : 0.0;
  result.w = (tmp0.w >= tmp1.w) ? 1.0 : 0.0;
```

Section 2.14.5.24, SLT: Set On Less Than

The SLT instruction performs a component-wise comparison of the two operands. Each component of the result vector is 1.0 if the corresponding component of the first operand is less than that of the second, and 0.0 otherwise.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = (tmp0.x < tmp1.x) ? 1.0 : 0.0;
  result.y = (tmp0.y < tmp1.y) ? 1.0 : 0.0;
  result.z = (tmp0.z < tmp1.z) ? 1.0 : 0.0;
  result.w = (tmp0.w < tmp1.w) ? 1.0 : 0.0;
```

Section 2.14.5.25, SUB: Subtract

The SUB instruction performs a component-wise subtraction of the second operand from the first to yield a result vector.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = tmp0.x - tmp1.x;
  result.y = tmp0.y - tmp1.y;
  result.z = tmp0.z - tmp1.z;
  result.w = tmp0.w - tmp1.w;
```

Section 2.14.5.26, SWZ: Extended Swizzle

The SWZ instruction loads the single vector operand, and performs a swizzle operation more powerful than that provided for loading normal vector operands to yield an instruction vector.

After the operand is loaded, the "x", "y", "z", and "w" components of the result vector are selected by the first, second, third, and fourth matches of the <extSwizComp> pattern in the <extendedSwizzle> rule.

A result component can be selected from any of the four components of the operand or the constants 0.0 and 1.0. The result component can also be optionally negated. The following pseudocode describes the component selection method. "operand" refers to the vector operand, "select" is an enumerant where the values ZERO, ONE, X, Y, Z, and W correspond to the <extSwizSel> rule matching "0", "1", "x", "y", "z", and "w", respectively.

"negate" is TRUE if and only if the <optionalSign> rule in <extSwizComp> matches "-".

```
  float ExtSwizComponent(floatVec operand, enum select, boolean negate)
  {
      float result;
      switch (select) {
        case ZERO:  result = 0.0; break;
        case ONE:   result = 1.0; break;
        case X:     result = operand.x; break;
        case Y:     result = operand.y; break;
        case Z:     result = operand.z; break;
        case W:     result = operand.w; break;
      }
      if (negate) {
        result = -result;
      }
      return result;
  }
```

The entire extended swizzle operation is then defined using the following pseudocode:

```
  tmp = VectorLoad(op0);
  result.x = ExtSwizComponent(tmp, xSelect, xNegate);
  result.y = ExtSwizComponent(tmp, ySelect, yNegate);
  result.z = ExtSwizComponent(tmp, zSelect, zNegate);
  result.w = ExtSwizComponent(tmp, wSelect, wNegate);
```

"xSelect", "xNegate", "ySelect", "yNegate", "zSelect", "zNegate", "wSelect", and "wNegate" correspond to the "select" and "negate" values above for the four <extSwizComp> matches.

Since this instruction allows for component selection and negation for each individual component, the grammar does not allow the use of the normal swizzle and negation operations allowed for vector operands in other instructions.

Section 2.14.5.27, XPD: Cross Product

The XPD instruction computes the cross product using the first three components of its two vector operands to generate the x, y, and z components of the result vector. The w component of the result vector is undefined.

```
  tmp0 = VectorLoad(op0);
  tmp1 = VectorLoad(op1);
  result.x = tmp0.y * tmp1.z - tmp0.z * tmp1.y;
  result.y = tmp0.z * tmp1.x - tmp0.x * tmp1.z;
  result.z = tmp0.x * tmp1.y - tmp0.y * tmp1.x;
```

Section 2.14.6, Program Matrices

In addition to GL's conventional matrices, several additional program matrices are available for use as program parameters. These matrices have names of the form MATRIX<i>_ARB where <i> is between zero and <n>-1 where <n> is the value of the implementation-dependent constant

MAX_PROGRAM_MATRICES_ARB. The MATRIX<i>_ARB constants obey MATRIX<i>_ARB = MATRIX0_ARB + <i>. The value of MAX_PROGRAM_MATRICES_ARB must be at least eight. The maximum stack depth for program matrices is defined by the MAX_PROGRAM_MATRIX_STACK_DEPTH_ARB and must be at least 1.

Section 2.14.7 Required Vertex Program State

The state required to support program objects of all targets consists of:

an integer for the program error position, initially -1;

an array of ubytes for the program error string, initially empty;

and the state that must be maintained to indicate which integers are currently in use as program object names.

The state required to support the vertex program target consists of:

a bit indicating whether or not program mode is enabled, initially disabled;

a bit indicating whether or not vertex program two-sided color mode is enabled, initially disabled;

a bit indicating whether or not vertex program point size mode is enabled, initially disabled;

a set of MAX_PROGRAM_ENV_PARAMETERS_ARB four-component floating-point program environment parameters, initially set to (0,0,0,0);

and an unsigned integer naming the currently bound vertex program, initially zero.

The state required for each vertex program object consists of:

an unsigned integer indicating the program object name;

an array of type ubyte containing the program string, initially empty;

an unsigned integer holding the length of the program string, initially zero;

an enum indicating the program string format, initially PROGRAM_FORMAT_ASCII_ARB;

five unsigned integers holding the number of instruction, temporary variable, vertex attribute binding, address register, and program parameter binding resources used by the program, initially all zero;

five unsigned integers holding the number of native instruction, temporary variable, vertex attribute binding, address register, and program parameter binding resources used by the program, initially all zero;

and a set of MAX_PROGRAM_LOCAL_PARAMETERS_ARB four-component floating-point program local parameters, initially set to (0,0,0,0).

Initially, no vertex program objects exist.

Additions to Chapter 3 of the OpenGL 1.3 Specification (Rasterization)

Modify Section 3.3, Points (p. 63)

(replace the first paragraph) When vertex program mode and vertex progam point size mode are both enabled, the point size used for point rasterization is taken from the transformed vertex's point size attribute. Otherwise, it is controlled with

```
void PointSize(float size);
```

size specifies the width or diameter of a point. The initial point size value is 1.0. A value less than or equal to zero results in the error INVALID_VALUE.

Vertex program point size mode is enabled and disabled by calling Enable or Disable with the symbolic value VERTEX_PROGRAM_POINT_SIZE_ARB.

Modify Section 3.9, Color Sum (p. 154)

After texturing, a fragment has two RGBA colors: a primary color c_pri (which texturing, if enabled, may have modified) and a secondary color c_sec. If color sum is enabled, the R, G, and B components of these two colors are summed, and with the A component of the primary color produce a single post-texturing RGBA color c. The components of c are then clamped to the range [0,1]. If color sum is disabled, then c_pri is assigned to the post-texturing color.

Color sum is enabled or disabled using the generic Enable and Disable commands, respectively, with the symbolic constant COLOR_SUM_ARB. If vertex program mode is disabled and lighting is enabled, the color sum stage is always applied, ignoring the value of COLOR_SUM_ARB.

The state required is a single bit indicating whether color sum is enabled or disabled. In the initial state, color sum is disabled.

Modify Section 3.10, Fog (p. 154)

(modify second paragraph) This factor f may be computed according to one of three equations:

```
        f = exp(-d*c),                                (3.24)
        f = exp(-(d*c)^2), or                         (3.25)
        f = (e-c)/(e-s)                               (3.26)
```

If vertex program mode is enabled or if the fog source (as defined below) is FOG_COORDINATE_EXT, then c is the fragment's fog coordinate. Otherwise, the c is the eye-coordinate distance from the eye, (0,0,0,1) in eye-coordinates, to the fragment center. ...

Additions to Chapter 4 of the OpenGL 1.3 Specification (Per-Fragment Operations and the Framebuffer)

None

Additions to Chapter 5 of the OpenGL 1.3 Specification (Special Functions)

Modify Section 5.1, Evaluators (p. 181)

(modify next-to-last paragraph, p. 184) For MAP VERTEX 3, let q = p. For MAP VERTEX 4, let q=(x/w,y/w,z/w), where (x; y; z;w) = p. Then let

```
        dq   dq
    m = -- x --.
        du   dv
```

The the generated analytic normal, n, is given by n=m if vertex program mode is enabled or by n=m/|m| if vertex program mode is disabled.

Modify Section 5.4, Display Lists (p. 191)

(modify third paragraph, p. 195) ... These are IsList, GenLists, ..., IsProgramARB, GenProgramsARB, DeleteProgramsARB, and VertexAttribPointerARB, EnableVertexAttribArrayARB, DisableVertexAttribArrayARB, as well as IsEnabled and all the Get commands (chapter 6).

Additions to Chapter 6 of the OpenGL 1.3 Specification (State and State Requests)

Modify Section 6.1.2, Data Conversions (p. 198)

(add before last paragraph, p. 198) The matrix selected by the current matrix mode can be queried by calling GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev with <pname> set to CURRENT_MATRIX_ARB; the matrix will be returned in transposed form with <pname> set to TRANSPOSE_CURRENT_MATRIX_ARB. The depth of the selected matrix stack can be queried with <pname> set to CURRENT_MATRIX_STACK_DEPTH_ARB. Querying CURRENT_MATRIX_ARB and CURRENT_MATRIX_STACK_DEPTH_ARB is the only means for querying the matrix and matrix stack depth of the program matrices described in section 2.14.6.

Modify Section 6.1.11, Pointer and String Queries (p. 206)

(modify last paragraph, p. 206) ... The possible values for <name> are VENDOR, RENDERER, VERSION, EXTENSIONS, and PROGRAM_ERROR_STRING_ARB.

(add after last paragraph of section, p. 207) Queries of PROGRAM_ERROR_STRING_ARB return a pointer to an implementation-dependent program load error string. If the last call to ProgramStringARB failed to load a program, the returned string describes at least one reason why the program failed to load. If the last call to ProgramStringARB successfully loaded a program, the returned string may be empty (containing only a zero terminator) or may contain one or more implementation-dependent warning messages. The contents of the error string are guaranteed to remain constant only until the next ProgramStringARB command, which may overwrite the error string.

Insert a new Section 6.1.12, Program Queries (p. 207), between existing sections 6.1.11 and 6.1.12.

Section 6.1.12, Program Queries

The commands

```
  void GetProgramEnvParameterdvARB(enum target, uint index,
                                   double *params);
  void GetProgramEnvParameterfvARB(enum target, uint index,
                                   float *params);
```

obtain the current value for the program environment parameter numbered <index> for the given program target <target>, and places the information in the array <params>. The error INVALID_ENUM is generated if <target> specifies a nonexistent program target or a program target that does not support program environment parameters. The error INVALID_VALUE is generated if <index> is greater than or equal to the implementation-dependent number of supported program environment parameters for the program target.

When <target> is VERTEX_PROGRAM_ARB, each program parameter returned is an array of four values.

The commands

```
  void GetProgramLocalParameterdvARB(enum target, uint index,
                                     double *params);
  void GetProgramLocalParameterfvARB(enum target, uint index,
                                     float *params);
```

obtain the current value for the program local parameter numbered <index> belonging to the program object currently bound to <target>, and places the information in the array <params>. The error INVALID_ENUM is generated if <target> specifies a nonexistent program target or a program target that does not support program local parameters. The error INVALID_VALUE is generated if <index> is greater than or equal to the implementation-dependent number of supported program local parameters for the program target.

When the program target type is VERTEX_PROGRAM_ARB, each program local parameter returned is an array of four values.

The command

```
  void GetProgramivARB(enum target, enum pname, int *params);
```

obtains program state for the program target <target>, writing the state into the array given by <params>. GetProgramivARB can be used to determine the properties of the currently bound program object or implementation limits for <target>.

If <pname> is PROGRAM_LENGTH_ARB, PROGRAM_FORMAT_ARB, or PROGRAM_BINDING_ARB, GetProgramivARB returns one integer holding the program string length (in bytes), program string format, and program name, respectively, for the program object currently bound to <target>.

If <pname> is MAX_PROGRAM_LOCAL_PARAMETERS_ARB or MAX_PROGRAM_ENV_PARAMETERS_ARB, GetProgramivARB returns one integer holding the maximum number of program local parameters or program environment parameters, respectively, supported for the program target <target>.

If <pname> is MAX_PROGRAM_INSTRUCTIONS_ARB, MAX_PROGRAM_TEMPORARIES_ARB, MAX_PROGRAM_PARAMETERS_ARB, MAX_PROGRAM_ATTRIBS_ARB, or MAX_PROGRAM_ADDRESS_REGISTERS_ARB, GetProgramivARB returns a single integer giving the maximum number of instructions, temporaries, parameters, attributes, and address registers that can be used by a program of type <target>. If <pname> is PROGRAM_INSTRUCTIONS_ARB, PROGRAM_TEMPORARIES_ARB, PROGRAM_PARAMETERS_ARB, PROGRAM_ATTRIBS_ARB, or PROGRAM_ADDRESS_REGISTERS_ARB, GetProgramivARB returns a single integer giving the number of instructions, temporaries, parameters, attributes, and address registers used by the current program for <target>.

If <pname> is MAX_PROGRAM_NATIVE_INSTRUCTIONS_ARB, MAX_PROGRAM_NATIVE_TEMPORARIES_ARB, MAX_PROGRAM_NATIVE_PARAMETERS_ARB, MAX_PROGRAM_NATIVE_ATTRIBS_ARB, or MAX_PROGRAM_NATIVE_ADDRESS_REGISTERS_ARB, GetProgramivARB returns a single integer giving the maximum number of native instruction, temporary, parameter, attribute, and address register resources available to a program of type <target>. If <pname> is PROGRAM_NATIVE_INSTRUCTIONS_ARB, PROGRAM_NATIVE_TEMPORARIES_ARB, PROGRAM_NATIVE_PARAMETERS_ARB, PROGRAM_NATIVE_ATTRIBS_ARB, or PROGRAM_NATIVE_ADDRESS_REGISTERS_ARB, GetProgramivARB returns a single integer giving the number of native instruction, temporary, parameter, attribute, and address register resources consumed by the program currently bound to <target>. Native resource counts will reflect the results of implementation-dependent scheduling and optimization algorithms applied by the GL, as well as emulation of non-native features. If <pname> is PROGRAM_UNDER_NATIVE_LIMITS_ARB, GetProgramivARB returns 0 if the native resource consumption of the program currently bound to <target> exceeds the number of available resources for any resource type, and 1 otherwise.

The command

```
  void GetProgramStringARB(enum target, enum pname, void *string);
```

obtains the program string for the program object bound to <target> and places the information in the array <string>. <pname> must be PROGRAM_STRING_ARB. <n> ubytes are returned into the array program where <n> is the length of the program in ubytes, as returned by GetProgramivARB when <pname> is PROGRAM_LENGTH_ARB. The program string is always returned using the format given when the program string was specified.

The commands

```
  void GetVertexAttribdvARB(uint index, enum pname, double *params);
  void GetVertexAttribfvARB(uint index, enum pname, float *params);
  void GetVertexAttribivARB(uint index, enum pname, int *params);
```

obtain the vertex attribute state named by <pname> for the vertex attribute numbered <index> and places the information in the array <params>. <pname> must be one of VERTEX_ATTRIB_ARRAY_ENABLED_ARB, VERTEX_ATTRIB_ARRAY_SIZE_ARB, VERTEX_ATTRIB_ARRAY_STRIDE_ARB, VERTEX_ATTRIB_ARRAY_TYPE_ARB, VERTEX_ATTRIB_ARRAY_NORMALIZED_ARB, or CURRENT_VERTEX_ATTRIB_ARB. Note that all the queries except CURRENT_VERTEX_ATTRIB_ARB return client state. The error INVALID_VALUE is generated if <index> is greater than or equal to MAX_VERTEX_ATTRIBS_ARB. The error INVALID_OPERATION is generated if <index> is zero and <pname> is CURRENT_VERTEX_ATTRIB_ARB, as there is no current value for vertex attribute zero.

The command

```
  void GetVertexAttribPointervARB(uint index, enum pname, void **pointer);
```

obtains the pointer named <pname> for vertex attribute numbered <index> and places the information in the array <pointer>. <pname> must be VERTEX_ATTRIB_ARRAY_POINTER_ARB. The INVALID_VALUE error is generated if <index> is greater than or equal to MAX_VERTEX_ATTRIBS_ARB.

The command

```
  boolean IsProgramARB(uint program);
```

returns TRUE if <program> is the name of a program object. If <program> is zero or is a non-zero value that is not the name of a program object, or if an error condition occurs, IsProgramARB returns FALSE. A name returned by GenProgramsARB, but not yet bound, is not the name of a program object.

Concerning Section 6.1.12, Saving and Restoring State (p. 207):

(no actual modifications to the spec) Only the enables, current vertex attributes, and vertex array state introduced by this extension can be pushed and popped. See the attribute column in Table X.6 for determining what vertex program state can be pushed and popped with PushAttrib, PopAttrib, PushClientAttrib, and PopClientAttrib.

Additions to Appendix A of the OpenGL 1.3 Specification (Invariance)

Add to end of Section A.3 (p. 242):

Rule 4. Vertex program instructions not relevant to the calculation of any result must have no effect on that result.

Rule 5. Vertex program instructions relevant to the calculation of any result must always produce the identical result.

Instructions relevant to the calculation of a result are any instructions in a sequence of instructions that eventually determine the source values for the calculation under consideration.

There is no guaranteed invariance between vertices transformed by conventional GL vertex transform mode and vertices transformed by vertex program mode. Multi-pass rendering algorithms that require rendering invariances to operate correctly should not mix conventional GL vertex transform mode with vertex program mode for different rendering passes, except by using the position invariance option (section 2.14.4.5.1) in all vertex program mode passes. However, such algorithms will operate correctly if the algorithms limit themselves to a single mode of vertex transformation.

Additions to the AGL/GLX/WGL Specifications

Program objects are shared between AGL/GLX/WGL rendering contexts if and only if the rendering contexts share display lists. No change is made to the AGL/GLX/WGL API.

Changes to program objects shared between multiple rendering contexts will be serialized (i.e., the changes will occur in a specific order).

Changes to a program object made by one rendering context are not guaranteed to take effect in another rendering context until the other calls BindProgram to bind the program object.

When a program object is deleted by one rendering context, the object itself is not destroyed until it is no longer the current program object in any context. However, the name of the deleted object is removed from the program object name space, so the next attempt to bind a program using the same name will create a new program object. Recall that destroying a program object bound in the current rendering context effectively unbinds the object being destroyed.

Dependencies on EXT_vertex_weighting and ARB_vertex_blend

If EXT_vertex_weighting and ARB_vertex_blend are both not supported, all discussions of vertex weights should be removed.

In particular, references to vertex weights should be removed from Table X.1, and the description of ArrayElement in section 2.8. The line

```
  "weight" <vtxOptWeightNum>
```

should be removed from the <vtxAttribItem> grammar rule, and the grammar rules <vtxOptWeightNum> and <vtxWeightNum> should be deleted. "vertex.weight" and "vertex.weight[n]" should be removed from Table X.2. The discussion of vertex weights in section 2.14.3.1 should be removed.

Additionally, the first line of Table X.3.8 should be modified to read:

Binding	Underlying State
state.matrix.modelview	modelview matrix

Dependencies on ARB_matrix_palette:

If ARB_matrix_palette is not supported, all discussions of per-vertex matrix indices and the matrix palette should be removed.

In particular, the reference to matrix indices should be removed from the description of ArrayElement in section 2.8. The line

```
  "matrixindex" "[" <vtxWeightNum> "]"
```

should be removed from the <vtxAttribItem> grammar rule. The line

```
  "palette" "[" <statePaletteMatNum> "]"
```

should be removed from the <stateMatrixName> grammar rule, and the

<statePaletteMatNum> grammar rule should be removed entirely. "vertex.matrixindex[n]" should be removed from Table X.2, and "state.matrix.palette[n]" should be removed from Table X.3.8. The discussion of vertex matrix indices in section 2.14.3.1 should be removed.

Dependencies on EXT_point_parameters and ARB_point_parameters

The discussion of point size determination in EXT/ARB_point_parameters should qualified to indicate that this functionality only applies when vertex program mode is disabled.

If EXT/ARB_point_parameters is not supported, references to point parameter state should be eliminated. In particular,

"attenuation"

should be eliminated from the <statePointProperty> grammar rule, and the corresponding entries in Table X.3.7 should be eliminated.

Additionally, references to the minimum and maximum point sizes and the fade threshold should be removed from Table X.3.7 and the explanatory text immediately thereafter. The components column of the "state.point.size" binding in Table X.3.7 should read (s,0,0,1).

Even if EXT/ARB_point_parameters is not supported, the point size result (result.pointsize) still operates as specified.

Dependencies on EXT_fog_coord

If EXT_fog_coord is not supported, references to fog coordinates should be removed from Table X.1, and the description of ArrayElement in section 2.8. The line "fogcoord" should be removed from the <vtxAttribItem> grammar rule, and "vertex.fogcoord" should be removed from Table X.2. Also, the use of FOG_COORDINATE_SOURCE_EXT in section 3.10 should be removed.

Even if EXT_fog_coord is not supported, the fog coordinate output (result.fogcoord) still operates as specified. When in vertex program mode, there are no well-defined eye coordinates that could be used for fog. This means that the functionality of EXT_fog_coord is required to implement ARB_vertex_program even if the EXT_fog_coord extension itself is not supported.

Dependencies on EXT_secondary_color

If EXT_secondary_color is not supported, references to secondary color should be removed from Table X.1, and the description of ArrayElement in section 2.8. The line "secondary" should be removed from the <vtxOptColorType> grammar rule, and "vertex.color.secondary" should be removed from Table X.2.

Even if EXT_secondary_color is not supported, the secondary color results (result.color.secondary, result.color.front.secondary, result.color.back.secondary) still operate as specified in program mode, and when in program mode, the color sum enable behaves exactly as specified in EXT_secondary_color. These vertex result registers are required to implement OpenGL 1.2's separate specular mode within a vertex program.

The color sum enable enumerant from EXT_secondary_color has been brought over and renamed to COLOR_SUM_ARB. The enumerant value itself is unchanged from EXT_secondary_color.

Dependencies on ARB_transpose_matrix

If ARB_transpose_matrix is not supported, the discussion of TRANSPOSE_CURRENT_MATRIX_ARB in the edits to section 6.1.2 should be removed.

Interactions with NV_vertex_program

The existing NV_vertex_program extension, if supported, also provides a similar vertex programming model. This extension is incompatible with NV_vertex_program in a number of different ways. Mixing the two models in a single application is possible but not recommended. The interactions between the extensions are defined below.

Functions, enumerants, and programs defined in NV_vertex_program are called "NV functions", "NV enumerants", and "NV programs" respectively. Functions, enumerants, and programs defined in ARB_vertex_program are called "ARB functions", "ARB enumerants", and "ARB programs" respectively.

The following enumerants are identical in the two extensions:

ARB_vertex_program	NV_vertex_program
VERTEX_PROGRAM_ARB	VERTEX_PROGRAM_NV
VERTEX_PROGRAM_POINT_SIZE_ARB	VERTEX_PROGRAM_POINT_SIZE_NV
VERTEX_PROGRAM_TWO_SIDE_ARB	VERTEX_PROGRAM_TWO_SIDE_NV
VERTEX_ATTRIB_ARRAY_SIZE_ARB	ATTRIB_ARRAY_SIZE_NV
VERTEX_ATTRIB_ARRAY_STRIDE_ARB	ATTRIB_ARRAY_STRIDE_NV
VERTEX_ATTRIB_ARRAY_TYPE_ARB	ATTRIB_ARRAY_TYPE_NV
CURRENT_VERTEX_ATTRIB_ARB	CURRENT_ATTRIB_NV
VERTEX_ATTRIB_ARRAY_POINTER_ARB	ATTRIB_ARRAY_POINTER_NV
PROGRAM_LENGTH_ARB	PROGRAM_LENGTH_NV
PROGRAM_STRING_ARB	PROGRAM_STRING_NV
PROGRAM_ERROR_POSITION_ARB	PROGRAM_ERROR_POSITION_NV
CURRENT_MATRIX_ARB	CURRENT_MATRIX_NV
CURRENT_MATRIX_STACK_DEPTH_ARB	CURRENT_MATRIX_STACK_DEPTH_NV
MAX_PROGRAM_MATRICES_ARB	MAX_TRACK_MATRICES_NV
MAX_PROGRAM_MATRIX_STACK_DEPTH_ARB	MAX_TRACK_MATRIX_STACK_DEPTH_NV

The following GL state is identical in the two extensions and can be set or queried using either NV functions or ARB functions.

- Vertex program mode enable.

- Vertex program point size mode enable.

- Vertex program two sided mode enable.

- Program error position.

- NV_vertex_program "program parameters" and ARB_vertex_program "program environment parameters".

- Current values of generic vertex attributes. Conventional and generic vertex attributes will alias according to the NV_vertex_program spec, which is permissible but optional under ARB_vertex_program.

- NV_vertex_program "tracking matrices" and ARB_vertex_program "program matrices". The NV and ARB enumerants passed to MatrixMode are different, however.

- Vertex attribute array sizes, types, strides, and pointers.

- Vertex program object names, targets, formats, program string, program string lengths, and residency information. The ARB and NV query functions operate differently. The ARB query function does not allow queries of target (passed in to the query) and residency information. The NV query function does not allow queries of program name (passed in to the query) or format. The format of NV programs is always PROGRAM_FORMAT_ASCII_ARB.

- Current matrix and current matrix stack depth.

- Implementation-dependent limits on number of tracking/program matrices and tracking/program matrix stack depth.

- Program object name space. Program objects are created differently in the NV and ARB specs. Under the NV spec, program objects are created by calling LoadProgramNV. Under the ARB spec, program objects are created by calling BindProgramARB with an unused program name.

The following state is provided only by ARB_vertex_program:

- Program error string. Querying the error string after calling LoadProgramNV produces undefined results.

- Vertex attribute array normalization enables. Setting up vertex attribute arrays through NV functions will set the normalization enable appropriately based on the NV spec.

- Vertex program object resource counts and native resource counts. These values are undefined for NV programs.

- Vertex program local parameters. They can not be used by NV programs.

- Implementation-dependent limits on the number of program environment parameters, program local parameters, resource counts, and native resource counts. These limits are baked into the NV spec, except for native counts, which don't exist.

The following state is provided only by NV_vertex_program:

- TrackMatrix enables and transforms.

- Generic vertex attribute evaluator maps. The NV evaluator functionality will be supported even for ARB programs.

The following are additional functional differences between ARB_vertex_program and NV_vertex_program:

- ARB program temporaries, address registers, and result registers are initially undefined. The corresponding values in NV programs are initialized to (0,0,0,0), 0, and (0,0,0,1), respectively. ARB programs running on NV_vertex_program platforms can not rely on NV_vertex_program initialization behavior for temporaries or address registers, but result registers will be initialized to (0,0,0,1). In any event, ARB programs that rely on NV_vertex_program initialization may not behave properly on other platforms that support ARB_vertex_program but not NV_vertex_program.

- NV programs use a set of fixed variable and register names, with no support for user-defined variables. ARB programs provide no support for fixed variable names; all variables must be declared, explicitly or implicitly, in the program.

- ARB programs support parameter variables that can be bound to selected GL state variables, and are updated automatically when the underlying state changes. NV programs provide no such support; applications must set program parameters themselves.

- ARB programs allow program constants to be declared in the program text; NV programs require that constants be loaded into the program parameter array.

- ARB programs support program local parameters; NV programs do not. Applications using multiple NV programs must manage the shared program parameter array appropriately.

- ARB_vertex_program vertex array support provides a normalized flag to optionally normalize fixed-point array data to the [0,1] or [-1,1] range. ARB_vertex_program also provides several immediate-mode entry points with the same support. NV_vertex_program supports normalized data only for unsigned byte data types, and does not support non-normalized unsigned bytes. VertexAttrib4ub{v}NV was renamed to VertexAttrib4Nub{v}ARB to indicate that the 4ub call normalizes its parameters to a [0,1] range.

- ARB_vertex_blend and ARB_matrix_palette support are documented by the ARB spec, but not by the NV spec.

- ARB_vertex_program contains an OPTION mechanism for future extensibility, and a position invariant program option. Both features are found in NV_vertex_program1_1, but not in NV_vertex_program.

- NV_vertex_program supports a vertex state program target that allows programs to write to program parameters (VERTEX_STATE_PROGRAM_NV). No such support exists in ARB_vertex_program. Running a NV state program will update the program parameter/program environment parameter array, and such updates can be visible through ARB programs.

- LoadProgramNV entry point was changed to ProgramStringARB to match OpenGL convention that a verb should not be included in a command name that merely sets state.

- The formal parameter name for program objects was "id" in NV_vertex_program; in ARB_vertex_program, this formal name is now "program" to match how texture object routines name their formal texture object names "texture".

- NV_vertex_program has language that makes it sound that LoadProgramNV (ProgramStringARB) only accepts the VERTEX_PROGRAM_NV target and the start token must be "!!VP1.0". This extension clarifies the language so that it is clear that other targets and start token types are permitted.

- NV_vertex_program numeric requirements are not present in the ARB spec. The ARB spec requires nothing more than the numeric requirements spelled out in section 2.1.1 (Floating-Point Computations) in the core specification.

- ARB programs allow single instructions to source multiple distinct vertex attributes or program parameters. NV programs do not. On current NV_vertex_program hardware, such instructions may require additional instructions and temporaries to execute.

- ARB programs support the folowing instructions not supported by NV "VP1.0" programs:

  * ABS: absolute value. Supported on VP1.1 NV programs, but not on VP1.0 programs. Equivalent to "MAX dst, src, -src".

  * EX2: exponential base 2. On VP1.0 and VP1.1 hardware, this instruction will be emulated using EXP and a number of additional instructions.

  * FLR: floor. On VP1.0 and VP1.1 hardware, this instruction will be emulated using an EXP and an ADD instruction.

  * FRC: fraction. On VP1.0 and VP1.1 hardware, this instruction will be emulated using an EXP instruction, and possibly a MOV instruction to replicate the scalar result.

  * LG2: logarithm base 2. On VP1.0 and VP1.1 hardware, this instruction will be emulated using LOG and a number of additional instructions.

  * POW: exponentiation. On VP1.0 and VP1.1 hardware, this instruction will be emulated using LOG, MUL, and EXP instructions, and possibly additional instructions to generate a high-precision result.

  * SUB: subtraction. Supported on VP1.1 NV programs, but not on VP1.0 programs. Equivalent to "ADD dst, src1, -src2".

  * SWZ: extended swizzle. On VP1.0 and VP1.1 hardware, this instruction will be emulated using a single MAD instruction and a program parameter constant.

  * XPD: cross product. On VP1.0 and VP1.1 hardware, this instruction will be emulated using a MUL and a MAD instruction.

- The COLOR_SUM_EXT enable is ignored when NV programs are executed (default secondary color outputs are zero) but not when ARB programs are executed (default secondary color outputs are undefined). The driver will take care of the color sum operation based on which type of program is currently bound.

- NV programs are required to write a vertex position; ARB programs are not.

- There is both an ARB and an NV boolean enable for each generic array (two booleans per generic array). Each generic array's NV enable is enabled with EnableClientState(VERTEX_ATTRIB_ARRAYn_NV) or disabled with DisableClientState(VERTEX_ATTRIB_ARRAYn_NV) while each generic array's ARB enable is enabled with EnableVertexAttribArrayARB(n) and disabled with DisableVertexAttribArrayARB(n).

  Enabling (or disabling) an ARB generic array enables (or disables) BOTH the NV and ARB generic array booleans.

  However enabling (or disabling) the NV generic array enable changes only the NV generic array enable (the ARB enable is UNchanged).

  When an enabled valid current vertex program (whether specified as an ARB or NV vertex program) is bound, the NV generic array enables are considered (and the ARB enables are ignored). If a given NV generic array enable is true, the corresponding generic array state is applied. However if there is an enabled valid vertex program and a particular NV generic array is disabled, then the corresponding conventional aliased array state is applied.

  When the current vertex program is disabled or not valid (so conventional vertex processing is performed), the ARB generic array enables are considered (and the NV enables are ignored). If a given ARB generic array enable is true, the corresponding generic array state is applied. However if the current vertex program is disabled or NOT valid and a particular ARB generic array is disabled, then the corresponding conventional aliased array state is applied.

  This behavior means generic vertex arrays can be applied to conventional vertex processing when the ARB generic vertex array enable boolean is true. For example, you can send normalized UNSIGNED_SHORT texture coordinate set arrays as aliased generic vertex arrays where conventionally UNSIGNED_SHORT texture coordinate set arrays are unnormalized.

NV_vertex_program interaction Issues:

- Should matrix tracking support extend to ARB program environment parameters?

Interactions with EXT_vertex_shader

The existing EXT_vertex_shader extension, if supported, also provides a similar vertex programming model. This extension is incompatible with

ARB_vertex_program in a number of different ways. Mixing the two models in a single application is possible but not recommended. The interactions between the extensions are defined below.

First, it should be trivially noted that an EXT_vertex_shader "shader" serves the same purpose as an ARB_vertex_program "program". The two terms will be used interchangeably throughout this discussion.

The most obvious difference between the two extensions is that the definition of the vertex program is accomplished in EXT_vertex_shader through the use of instruction-specifying procedure calls and is accomplished in ARB_vertex_program by providing a textual string describing the program. This is mostly a distinction of interface rather than functionality.

Each extension provides its own distinct set of GL state, entry points, and enumerants. However, there are several areas of overlap both in conceptual framework and in programming model that are worth noting for those familiar with both API's.

1. Resource terminology and types

   Both ARB_vertex_program and EXT_vertex_shader offer access to similar types of resources for use by vertex programs.

   The following terms describe roughly equivalent resources in their respective extensions:

EXT_vertex_shader	ARB_vertex_program	Note
instructions	instructions	
variants	attributes	
locals	temporaries	
local constants	parameters bound to inline constants	(a)
invariants	parameters bound to GL state and program environment parameters	(b)

   a. ARB_vertex_program has no intrinsic storage type that corresponds to EXT_vertex_shader's LOCAL_CONSTANT storage type, but rather supports program parameters bound to inline constant vectors specified within the program text. This essentially makes LOCAL_CONSTANT a special case of an ARB_vertex_program program parameter. The values of these inline constant parameters can not be changed without redefining the program itself, just like the values of EXT_vertex_shader LOCAL_CONSTANTs.

   b. ARB_vertex_program has no intrinsic storage type that corresponds to EXT_vertex_shader's INVARIANT storage type, but rather supports program parameters bound to GL state variables, program environment parameters, and program local parameters. This essentially makes INVARIANT a special case of an ARB_vertex_program program parameter. The values of these bound program parameters can be changed without redefining the program itself, but remain constant from vertex to vertex during vertex program execution, just like the values of EXT_vertex_shader INVARIANTs.

```
    ARB_vertex_program also adds the concept of a program local parameter,
    which has no direct analogue in EXT_vertex_shader, as it represents a
    parameter that is stored locally with the program object, but the
    values of these parameters can be changed without redefining the
    program itself.

 2. Resource usage queries

    Both ARB_vertex_program and EXT_vertex_shader provide queries to assist
    in determining the resource usage of a given shader and whether the
    shader would "fit" within the limits imposed by the underlying hardware
    implementation. The application can investigate the maximum numbers of
    shader resources supported by an implementation, shader resources
    available in hardware, and resources consumed by a given shader after
    being compiled into the implementation's native representation.

    In EXT_vertex_shader (see the end of section 2.14 of the
    EXT_vertex_shader specification), the queries are handled by glGet.

    In ARB_vertex_programs (see section 2.14.3.7 of this specification),
    similar queries are handled by GetProgramivARB, with a target of
    VERTEX_PROGRAM_ARB.

    The following queries exist in both extensions and serve roughly
    equivalent purposes in each:
```

EXT_vertex_shader	ARB_vertex_program
MAX_VERTEX_SHADER_INSTRUCTIONS_EXT	MAX_PROGRAM_INSTRUCTIONS_ARB
MAX_VERTEX_SHADER_VARIANTS_EXT	MAX_PROGRAM_ATTRIBS_ARB
MAX_VERTEX_SHADER_LOCALS_EXT	MAX_PROGRAM_TEMPORARIES_ARB
MAX_OPTIMIZED_VERTEX_SHADER_INSTRUCTIONS_EXT	MAX_PROGRAM_NATIVE_INSTRUCTIONS_ARB
MAX_OPTIMIZED_VERTEX_SHADER_VARIANTS_EXT	MAX_PROGRAM_NATIVE_ATTRIBS_ARB
MAX_OPTIMIZED_VERTEX_SHADER_LOCALS_EXT	MAX_PROGRAM_NATIVE_TEMPORARIES_ARB
VERTEX_SHADER_INSTRUCTIONS_EXT	PROGRAM_NATIVE_INSTRUCTIONS_ARB
VERTEX_SHADER_VARIANTS_EXT	PROGRAM_NATIVE_ATTRIBS_ARB
VERTEX_SHADER_LOCALS_EXT	PROGRAM_NATIVE_TEMPORARIES_ARB
VERTEX_SHADER_OPTIMIZED_EXT	PROGRAM_UNDER_NATIVE_LIMITS_ARB

```
    ARB_vertex_program offers additional queries to account for differences
    in some of the resource definitions (program environment parameters and
    program local parameters, address registers, etc.) as well as the
    ability to separately query a compiled program's resource usage
    according to the specification versus a possibly more efficient
    resource usage obtained by passing the program through by a "smart"
    compiler.

    The following queries do not exist in ARB_vertex_program due to the
    slightly different resource models:
```

EXT_vertex_shader	ARB_vertex_program
{MAX_}{OPTIMIZED_}VERTEX_SHADER_INVARIANTS_EXT	(a)
{MAX_}{OPTIMIZED_}VERTEX_SHADER_LOCAL_CONSTANTS_EXT	(a)

```
      a. ARB_vertex_program coalesces all of the different program
         parameters (environment, local, inline constant, and those bound
```

to GL state) into a single queryable resource for PROGRAM_PARAMETERS. EXT_vertex_shader provides separate queries even though these parameters may consume the same resource on some implementations.

The following queries do not exist in EXT_vertex_shader due to the slightly different resource models:

EXT_vertex_shader	ARB_vertex_program
(b)	PROGRAM_*_ARB
(c)	{MAX_}{NATIVE_}PROGRAM_PARAMETERS_ARB
(d)	{MAX_}{NATIVE_}PROGRAM_ADDRESS_REGISTERS_ARB

b. These queries are used to find out how many resources a given program used according to the specification, *before* running the program through an optimizing compiler. This distinction is not made in EXT_vertex_shader.

c. These queries are used to find out how many parameters were used by a program or are allowed by an implementation, in total without distinguishing between environment parameters, program local parameters, inline constant parameters, or parameters bound to GL state. EXT_vertex_shader does not provide this information.

d. EXT_vertex_shader does not provide have any address register resources since all dynamic array references are handled with the atomic OP_INDEX instruction.

3. Symbols and variable names

In EXT_vertex_shader resources that represent storage locations (i.e. INVARIANTS, VARIANTS, LOCALS, LOCAL_CONSTANTS) are abstractly referenced through a GL-allocated symbol id obtained from GenSymbolsEXT. This level of abstraction is provided to allow the implementation to make hardware-dependent decisions about the best way to arrange, allocate, and re-use hardware resources.

Though ARB_vertex_program does not use symbol id's to refer to similar types of resources, it does provide similar functionality by allowing a vertex program to declare arbitrarily named variables for each resource in use. These names are assigned using the declaration syntax associated with the "PARAM", "ATTRIB", "TEMP", and "OUTPUT", and "ADDRESS" keywords.

4. Program management

With the exception of the actual program specification itself, EXT_vertex_shader and ARB_vertex_program have very similar program management API's.

The following procedures serve roughly equivalent functions in their respective extensions.

EXT_vertex_shader   ARB_vertex_program

-----------------	------------------
BindVertexShaderEXT	BindProgramARB
GenVertexShadersEXT	GenProgramsARB
DeleteVertexShaderEXT	DeleteProgramsARB

The following procedures are used in EXT_vertex_shader to define the program instruction sequence, and are not present in ARB_vertex_program since the string provided to ProgramStringARB fully defines the program contents.

```
    ShaderOp1EXT
    ShaderOp2EXT
    ShaderOp3EXT
    SwizzleEXT
    WriteMaskEXT
    InsertComponentEXT
    ExtractComponentEXT
```

5. Data specification routines

With the exception of the discrepancies in data types and resource names described above, EXT_vertex_shader and ARB_vertex_program provide similar program data specification and "current data query" API's.

The following procedures serve roughly equivalent functions in their respective extensions:

EXT_vertex_shader	ARB_vertex_program	Note
SetInvariantEXT	ProgramEnvParameter4*ARB	(a)
GetInvariant*vEXT	GetProgramEnvParameter*vARB	(a)
Variant*vEXT	VertexAttrib*ARB	
VariantPointerEXT	VertexAttribPointerARB	
GetVariant*vEXT	GetVertexAttrib*vARB	
GetVariantPointervEXT	GetVertexAttribPointervARB	
EnableVariantClientStateEXT	EnableVertexAttribArrayARB	
DisableVariantClientStateEXT	DisableVertexAttribArrayARB	
IsVariantEnabledEXT	GetVertexAttrib*vARB	(b)

a. See item #1 and #2 for more information on the relationship between EXT_vertex_shader invariants and ARB_vertex_program program parameters.

b. The enabled state of an attribute array in ARB_vertex_program can be queried with GetVertexAttrib*v and a parameter of VERTEX_ATTRIB_ARRAY_ENABLED_ARB. In EXT_vertex_shader there is a dedicated enabled query procedure.

However, there are some data specification routines in EXT_vertex_shader that have no procedure call analogue in ARB_vertex_program as their functions are subsumed by the string representation of the program itself.

The following procedures in EXT_vertex_shader have functionality roughly covered by the following strings within the program text in ARB_vertex_shader:

```
    EXT_vertex_shader            ARB_vertex_program           Note
    -----------------            ------------------           -----
    SetLocalConstantEXT          PARAM C = {<x>,<y>,<z>,<w>};  (c)

    BindLightParameterEXT        state.light[n].*
    BindMaterialParameterEXT     state.material.*              (d)
    BindTexGenParameterEXT       state.texgen[n].*

    BindTextureUnitParameterEXT

```

c. Note that while EXT_vertex_shader style local constants can be specified using inline constants in the program text, there is no functionality in ARB_vertex_program that corresponds to the GetLocalConstant*vEXT call. That is, program parameters bound to inline constant vectors can be set in the text, but not queried from the application.

d. Note that while EXT_vertex_shader supports binding material properties to variants, ARB_vertex_shader only supports binding them to program parameters (invariants). See item #11 below for more information.

e. Note that while EXT_vertex_shader supports binding color matrix if the ARB_imaging subset is supported, ARB_vertex_shader does not allow for such a binding. See item #11 below for more information.

6. Data types

EXT_vertex_shader supports data types of SCALAR, VECTOR, and MATRIX.

ARB_vertex_program intrinsically supports only vectors, though it allows for the definition of a matrix as a contiguous allocation of four row vectors. Some operations that, in EXT_vertex_shader require scalar inputs or scalar outputs, will, in ARB_vertex_program, use the selected component of the source vector as input and/or replicate their output to all components .

Further, EXT_vertex_shader supports a pair of InsertComponents and ExtractComponents functions that are not available (nor required) in ARB_vertex_program, as they essentially provide for conversion between the SCALAR, VECTOR, and MATRIX data types.

7. Input swizzles and output write-masks

   In EXT_vertex_shader, write masks are specified as a type of "instruction", using WriteMaskEXT, while in ARB_vertex_program, write masks are specified as modifiers to the destination resource with writemask modifiers, such as ".xyz" or ".w".

   In EXT_vertex_shader, source operand swizzles (component re- ordering, negation, and hard-coding to the value 0 and +/- 1.0) are also specified as a type of "instruction", using SwizzleEXT.

   In ARB_vertex_program, swizzles can either be handled as instruction ("SWZ") or as part of a modifier of the source argument to an instruction. The only differences between the two methods is that the source modifiers in ARB_vertex_program do not provide the ability to use 0.0 and +/- 1.0, or negate individual components, while the "SWZ" instruction does.

8. Support for clipping and user clip planes

   Both extensions provide similar support for traditional clipping to the view frustum, namely that frustum clipping is not subsumed by vertex shader, or vertex program execution.

   Additionally, EXT_vertex_shader supports user clip planes by transforming the user clip planes from eye-space into clip space and clipping in the clip space coordinate system. This is supported as long as the projection matrix is non-singular.

   ARB_vertex_program provides similar functionality but only for programs specified using the "position invariant" option. For more information on user clip-plane support, see issue #20 and section 2.14.4.5.1 of this specification.

9. Support for glRasterPos

   EXT_vertex_shader does not support transforming the current raster position vertex by the current vertex shader, while ARB_vertex_program does.

10. Relative addressing.

   The string based syntax of ARB_vertex_program supports a relative addressing model where a given declared array can be dynamically dereferenced by first loading a declared ADDRESS register, using the "ARL" instruction with a value obtained at program execution then using that named ADDRESS register as the index to dereference a declared array of parameters later on. See section 2.14.3.5 of this specification for details.

   For example, in ARB_vertex_program you can specify the following piece of a program.

```
    PARAM arr[5]  = { program.env[0..4] };
    ADDRESS addr;
```

```
        ATTRIB v1 = vertex.attrib[1];
        ARL addr, v1;
        MOV result, arr[addr.x + 1];
```

    EXT_vertex_shader supports relative addressing as as a single atomic
    operation through the use of the instruction OP_INDEX_EXT, as in

```
        ShaderOp2EXT(OP_INDEX_EXT, <res>, <arg1>, <arg2>).
```

    OP_INDEX_EXT supports relative addressing by taking the value stored in
    the register referred to by <arg1> and adding that value to the register
    number referred to by <arg2>, and loading <res> with the value stored in
    the register at the resulting offset. EXT_vertex_shader has the
    requirement that the register referred to by <arg2> is allocated as one
    of a contiguous range of symbols obtained from a single call to
    GenSymbolsEXT.

    To achieve the same functionality as the above ARB_vertex_program, using
    EXT_vertex_shader, one could allocate a LOCAL symbol to hold a "fake"
    address register, and do a similar type of dynamic dereference
    operation, placing the output in a temporary LOCAL before giving it as
    an source argument to the "real" instruction.

```
     arr_contiguousArraySymbol =
          GenSymbolsEXT(GL_VECTOR_EXT, GL_LOCAL_EXT, GL_FULL_RANGE_EXT, 5);

     addr_fakeAddressRegSymbol =
          GenSymbolsEXT(GL_VECTOR_EXT, GL_LOCAL_EXT, GL_FULL_RANGE_EXT, 1);

     v1_srcSymbolForARLOp =
          GenSymbolsEXT(GL_VECTOR_EXT, GL_VARIANT_EXT, GL_FULL_RANGE_EXT, 1);

     temp =
          GenSymbolsEXT(GL_VECTOR_EXT, GL_LOCAL_EXT, GL_FULL_RANGE_EXT, 1);

     result_ForMovOpSymbol =
          GenSymbolsEXT(GL_VECTOR_EXT, GL_LOCAL_EXT, GL_FULL_RANGE_EXT, 1);

      // load fake ADDRESS register
      ExtractComponentEXT(
          addr_fakeAddressRegSymbol,
          v1_srcSymbolForARLOp,
          0);

      // do dynamic dereference into a temp
      ShaderOp2EXT(
          GL_OP_INDEX_EXT,
          temp,
          addr_fakeAddressRegSymbol,
          contiguousArraySymbol);

      // do operation we really wanted (MOV) using looked up src value
      ShaderOp1EXT(
          GL_OP_MOV_EXT,
          result_ForMovOpSymbol,
          temp,
          (arr_contiguousArraySymbol + 1));
```

11. Available GL state bindings

    Both EXT_vertex_shader and ARB_vertex_program offer the ability to bind program resources to pieces of OpenGL state so that the values of OpenGL state parameters are available to the program without the application having to copy the state values manually into program parameters.

    The two extensions differ in exactly which pieces of state are available to a vertex program, with the main difference being that ARB_vertex_program offers a more comprehensive set of state bindings.

    First, EXT_vertex_shader can bind pieces of GL state considered to be "scalar" values to a single SCALAR symbol, whereas ARB_vertex_program, which handles only vectors, packs up to 4 scalar bindings into a single vector parameter.

    Similarly, EXT_vertex_shader can bind pieces of GL state considered to be "matrix" values to a single MATRIX symbol, whereas ARB_vertex_program supports bindings to matrix data by using up to four vectors to store the rows of the matrix.

    Other differences between the state bindings available in both API's are listed below:

    a. In EXT_vertex_shader, the light attenuation factors (CONSTANT, LINEAR, QUADRATIC, and SPOT_EXPONENT), are available as separate SCALAR bindings.

       In ARB_vertex_program, the light attenuation factors are all packed into a single vector called state.light[n].attenuation with the CONSTANT, LINEAR, QUADRATIC, and SPOT_EXPONENT factors in the x,y,z, and w parameters respectively.

    b. In EXT_vertex_shader the spotlight direction (SPOT_DIRECTION) and spot light cutoff angle (SPOT_CUTOFF), are available as separate bindings.

       In ARB_vertex_program, these parameters are all packed into a single vector called state.light[n].spot.direction with the with the x,y,z parameters of the spotlight direction and the the *cosine* of the cutoff angle in the x,y,z, and w parameters respectively.

    c. In EXT_vertex_shader, the fog equation factors (FOG_DENSITY, FOG_START, FOG_END), are avaiable as separate SCALAR bindings.

       In ARB_vertex_program, the fog equation factors are all packed into a single vector called state.fog.params with the fog density, linear start, linear end, and pre-computed 1.0/ (end-start) factors in the x,y,z, and w parameters respectively.

    d. In EXT_vertex_shader, material properties can be bound to a variant (i.e. "attribute" in ARB_vertex_program terminology) and can change per vertex, and the changes take effect immediately.

In ARB_vertex_program, material properties can only be bound to program parameters, and any changes to material properties between a Begin/End pair are not guaranteed to take effect until the following End command.

e. In EXT_vertex_shader, the material shininess property is bound to a SCALAR variable.

   In ARB_vertex_program, the material shininess property is bound to a vector with elements { s, 0.0, 0.0, 1.0 } where "s" is the material shininess property.

f. In EXT_vertex_shader, a program can bind to the current modelview, projection, composite modelview-projection, color, and texture matrices only in their entirety.

   In ARB_vertex_program, a program can bind to individual rows of any matrix, with the exception of the color matrix, which is not available in ARB_vertex_program.

   Additionally, ARB_vertex_program adds the ability to bind to multiple modelview matrices, multiple palette matrices, and a set of matrices dedicated for use with vertex programs called "program matrices". Further, ARB_vertex_program offers the ability to bind to the inverse, transpose, and inverse_transpose of any of the matrices available for binding.

   If an application desires the functionality of binding to the color matrix in ARB_vertex_program, that application can use one of the other matrices, for instance program matrices, to store the current color matrix.

12. Instruction set differences.

In general, ARB_vertex_program's instruction set is a super-set of the EXT_vertex_shader instructions that take VECTOR inputs and produce VECTOR outputs. The versions of the EXT_vertex_shader instructions that take non-vector (i.e. SCALAR or MATRIX) operands are almost all available in vector form as well.

The instructions from each set correspond as follows:

EXT_vertex_shader	ARB_vertex_program	Note
OP_INDEX_EXT	<unavailable>	(a)
OP_NEGATE_EXT	<unavailable>	(b)
OP_DOT3_EXT	"DP3"	(c)
OP_DOT4_EXT	"DP4"	
OP_MUL_EXT	"MUL"	
OP_ADD_EXT	"ADD"	
OP_MADD_EXT	"MAD"	
OP_FRAC_EXT	"FRC"	
OP_MAX_EXT	"MAX"	
OP_MIN_EXT	"MIN"	
OP_SET_GE_EXT	"SGE"	
OP_SET_LT_EXT	"SLT"	
OP_CLAMP_EXT	<unavailable>	(d)

```
 OP_FLOOR_EXT            "FLR"
 OP_ROUND_EXT           <unavailable>         (e)
 OP_EXP_BASE_2_EXT       "EX2"                (f)
 OP_LOG_BASE_2_EXT       "LG2"                (g)
 OP_POWER_EXT            "POW"                (h)
 OP_RECIP_EXT            "RCP"                (i)
 OP_RECIP_SQRT_EXT       "RSQ"                (j)
 OP_SUB_EXT              "SUB"
 OP_CROSS_PRODUCT_EXT    "XPD"                (k)
 OP_MULTIPLY_MATRIX_EXT <unavailable>         (l)
 OP_MOV_EXT              "MOV"
<unavailable>            "ARL"                (a)
<unavailable>            "ABS"
<unavailable>            "LIT"
<unavailable>            "EXP"                (f)
<unavailable>            "LOG"                (g)
<unavailable>            "DPH"
<unavailable>            "DST"
```

There are a few minor differences, however.

a. EXT_vertex_shader's OP_INDEX_EXT is not available in ARB_vertex_program which uses the "ARL" instruction and array syntax to handle dynamically dereferencing source data. See item #10 above and the discussion of "ARL" in section 2.14.3.5.

b. EXT_vertex_shader's OP_NEGATE_EXT is not available in ARB_vertex_program. ARB_vertex_program can support a "NEGATE" operation through the use of swizzle modifiers on source operands or the "SWZ" instruction.

```
  MOV tempA, -tempB;
```

or

```
  SWZ tempA, -tempB, x,y,z,w;
```

c. The "w" component of EXT_vertex_shader's OP_DOT3_EXT instruction is left unchanged.

However, in ARB_vertex_program, the "w" component gets the same result as the "x", "y", and "z" components.

d. EXT_vertex_shader's OP_CLAMP_EXT is not available in ARB_vertex_program. ARB_vertex_program can support a "CLAMP" operation by using a pair of "MAX" and "MIN" instructions as in:

```
  # CLAMP arg1 to be within [arg2, arg3]
  MAX temp,   arg1, arg2;
  MIN result, temp, arg3;
```

e. EXT_vertex_shader's OP_ROUND_EXT is not available in ARB_vertex_program. ARB_vertex_program can support a "ROUND" operation by using a pair of "ADD" and "FLOOR" instructions as in:

```
  ADD   temp,   arg1, 0.5;
  FLOOR result, temp;
```

f. EXT_vertex_shader's OP_EXP_BASE_2_EXT is designed to support high precision calculations of base-2 exponentiation.

   ARB_vertex_program's "EX2" is the equivalent function, however ARB_vertex_program also offers an "EXP" function that is designed to support a lower precision approximation of base-2 exponentiation that can be further refined through an iterative process.

   On some implementations, both "EX2" and "EXP" may be carried out with the same high precision at no cost relative to each other. As such, if a vertex program is using "EXP" with the intent of iteratively refining the approximation by using several successive instructions it may be more efficient to use a single call to "EX2" and get the high precision with a single instruction.

   If on the other hand, a single approximation is good enough, there is no additional cost to using "EXP" on such implementations.

   Further note that in EXT_vertex_shader, OP_EXP_BASE_2_EXT is specified to take a scalar operand, whereas ARB_vertex_program's "EXP" and "EX2" instruction each take a vector operand, use the "x" component, and then write (partial) results to all components of a destination vector.

g. EXT_vertex_shader's OP_LOG_BASE_2_EXT is designed to support high precision calculations of base-2 logarithms.

   ARB_vertex_program's "LG2" is the equivalent function, however ARB_vertex_program also offers an "LOG" function that is designed to support a lower precision approximation of base-2 logarithms that can be further refined through an iterative process.

   On some implementations, both "LG2" and "LOG" may be carried out with the same high precision at no cost relative to each other. As such, if a vertex program is using "LOG" with the intent of iteratively refining the approximation by using several successive instructions it may be more efficient to use a single call to "LG2" and get the high precision with a single instruction.

   If on the other hand, a single approximation is good enough, there is no additional cost to using "LOG" on such implementations.

   Further note that in EXT_vertex_shader, OP_LOG_BASE_2_EXT is specified to take a scalar operand, whereas ARB_vertex_program's "LOG" and "LOG2" instruction each take a vector operand, use the "x" component, and then write (partial) results to all components of a destination vector.

h. EXT_vertex_shader's OP_POWER_EXT is designed to support high precision calculations of the power function.

   ARB_vertex_program's "POW" is the equivalent function.

   Further note that in EXT_vertex_shader, OP_POWER_EXT is specified to take a scalar operand, whereas ARB_vertex_program's "POW" instruction takes a vector operand, uses the "x" component, and replicates the same result to all components of a destination vector.

i. EXT_vertex_shader's OP_RECIP_EXT is specified to take a scalar operand, whereas ARB_vertex_program's "RCP" instruction takes a single component of a vector and replicates the same result to all components of the destination vector.

j. EXT_vertex_shader's OP_RECIP_SQRT_EXT is specified to take a scalar operand, whereas ARB_vertex_program's "RSQ" instruction takes a single component of a vector and replicates the same result to all components of the destination vector.

k. The "w" component of EXT_vertex_shader's OP_CROSS_PRODUCT_EXT instruction is forced to 1.0;

However, in ARB_vertex_program, the "w" component is left undefined and "writes to the w component of the destination are treated as disabled, regardless of the write mask specified in the XPD instruction".

l. EXT_vertex_shader's OP_MULTIPLY_MATRIX is not available in ARB_vertex_program. ARB_vertex_program can support a "MATRIX MULTIPLY" operation by using a series of "DP4" instructions as in:

```
PARAM mat[4] = { state.matrix.modelview };
DP4 result.x, vec, mat[0];
DP4 result.y, vec, mat[1];
DP4 result.z, vec, mat[2];
DP4 result.w, vec, mat[3];
```

13. Vertex provoking behavior

EXT_vertex_shader does not provoke vertex shader execution when variant 0 is specified (either using Variant*EXT, or variant arrays). Applications are required to use the conventional Vertex* or vertex arrays to provoke a vertex in both vertex shader mode and conventional mode. Variant 0 is considered current state and is queryable.

Conversely, ARB_vertex_program does provoke vertex program execution when attribute 0 is specified (either using VertexAttrib*vARB, or attribute arrays) in both vertex program mode and conventional mode. Attribute 0 is not considered current state and is not queryable.

For implementations that support both extensions, this means that if ARB_vertex_program is disabled, and EXT_vertex_shader is enabled, then specifying ARB_vertex_program's attribute 0 will still provoke execution of the currently bound EXT_vertex_shader defined shader.

14. Enabled state

On implementations that support both EXT_vertex_shader, and ARB_vertex_program, priority is given to ARB_vertex_program. That is to say, if both are enabled, the implementation uses the program defined by ARB_vertex_program and does not execute the currently bound EXT_vertex_shader shader unless or until ARB_vertex_program is subsequently disabled. Needless to say, it is not expected that a given application will actually attempt to use both vertex program API's at once.

GLX Protocol

The following rendering commands are sent to the server as part of a glXRender request:

```
    VertexAttrib1svARB
        2           12              rendering command length
        2           4189            rendering command opcode
        4           CARD32          index
        2           INT16           v[0]
        2                           unused

    VertexAttrib1fvARB
        2           12              rendering command length
        2           4193            rendering command opcode
        4           CARD32          index
        4           FLOAT32         v[0]

    VertexAttrib1dvARB
        2           16              rendering command length
        2           4197            rendering command opcode
        4           CARD32          index
        8           FLOAT64         v[0]

    VertexAttrib2svARB
        2           12              rendering command length
        2           4190            rendering command opcode
        4           CARD32          index
        2           INT16           v[0]
        2           INT16           v[1]

        8           FLOAT64         params[1]
        8           FLOAT64         params[2]
        8           FLOAT64         params[3]
```

The ProgramStringARB is potentially large, and hence can be sent in a glXRender or glXRenderLarge request.

ProgramStringARB

```
        2           16+len+p        rendering command length
        2           4217            rendering command opcode
        4           ENUM            target
        4           ENUM            format
        4           sizei           len
        len         LISTofBYTE      program
        p                           unused, p=pad(len)
```

If the command is encoded in a glxRenderLarge request, the command opcode and command length fields above are expanded to 4 bytes each:

```
        4           16+len+p        rendering command length
        4           4217            rendering command opcode
```

VertexAttribPointerARB, EnableVertexAttribArrayARB, and DisableVertexAttribArrayARB are entirely client-side commands.

The remaining commands are non-rendering commands. These commands are sent separately (i.e., not as part of a glXRender or glXRenderLarge request), using the glXVendorPrivateWithReply request:

    When transferring vertex attribute array elements, there may not be a
    protocol encoding that exactly matches the combination of combination of
    size, normalization enable, and data type in the array. If no match
    protocol encoding exists, the encoding for the corresponding 4-component
    attribute is used. v[1] and v[2] are set to zero if not specified in the
    vertex array. If v[3] is not specified in the vertex array, it is set to
    0x7F, 0x7FFF, 0x7FFFFFFF, 0xFF, 0xFFFF, or 0xFFFFFFFF for the
    VertexAttrib4NbvARB, VertexAttrib4NsvARB, VertexAttrib4NivARB,
    VertexAttrib4NubvARB, VertexAttrib4NusvARB, and VertexAttrib4NuivARB
    protocol encodings, respectively. v[3] is set to one if it is not
    specified in the vertex array for the the VertexAttrib4bvARB,
    VertexAttrib4svARB, VertexAttrib4ivARB, VertexAttrib4ubvARB,
    VertexAttrib4usvARB, and VertexAttrib4uivARB protocol encodings.

Errors

The error INVALID_VALUE is generated by any VertexAttrib*ARB or GetVertexAttrib*ARB command if <index> is greater than or equal to MAX_VERTEX_ATTRIBS_ARB.

The error INVALID_VALUE is generated by VertexAttribPointerARB or GetVertexAttribPointervARB if <index> is greater than or equal to MAX_VERTEX_ATTRIBS_ARB.

The error INVALID_VALUE is generated by VertexAttribPointerARB if <size> is not one of 1, 2, 3, or 4.

The error INVALID_VALUE is generated by VertexAttribPointerARB if <stride> is negative.

The error INVALID_VALUE is generated by EnableVertexAttribArrayARB or DisableVertexAttribArrayARB if <index> is greater than or equal to MAX_VERTEX_ATTRIBS_ARB.

The error INVALID_OPERATION is generated by ProgramStringARB if the program string <string> is syntactically incorrect or violates any semantic restriction of the execution environment of the specified program target <target>.

The error INVALID_OPERATION is generated by BindProgramARB if <program> is the name of a program whose target does not match <target>.

The error INVALID_VALUE is generated by any ProgramEnvParameter*ARB or GetProgramEnvParameter*ARB command if <index> is greater than or equal to the value of MAX_PROGRAM_ENV_PARAMETERS_ARB corresponding to the program target <target>.

The error INVALID_VALUE is generated by any ProgramLocalParameter*ARB or GetProgramLocalParameter*ARB command if <index> is greater than or equal to the value of MAX_PROGRAM_LOCAL_PARAMETERS_ARB corresponding to the program target <target>.

The error INVALID_OPERATION is generated if Begin, RasterPos, or any command that performs an explicit Begin is called when vertex program mode is enabled and the currently bound vertex program object does not contain a valid vertex program.

The error INVALID_OPERATION is generated by GetVertexAttrib*ARB if <index> is zero and <pname> is CURRENT_VERTEX_ATTRIB_ARB.

Table X.11. New Implementation-Dependent Values Introduced by ARB_vertex_program. Values queried by GetProgramivARB require a <pname> of VERTEX_PROGRAM_ARB.

Revision History

Rev.	Date	Author	Changes
46	07/25/07	mjk	Document how the ARB and NV generic arrays interact. This documents NVIDIA's long-standing implemented behavior.
45	09/27/04	pbrown	Fixed GLX protocol, removing the unused <pname> parameters for GetProgram{Env,Local}Parameter [df]vARB, leaving an unused CARD32 in its place. This was an error when propogating NV_vertex_program protocol, which did have a <pname> parameter.
44	09/12/03	pbrown	Fixed opcode table entry for "ARL" -- it takes a scalar operand as specified in the grammar.
43	08/17/03	pbrown	Fixed a couple minor typos (missing quotes) in the grammar.
42	05/01/03	pbrown	Clarified the handling of color sum; old text suggested that COLOR_SUM controlled the operation even when doing separate specular lighting.

```
    41    04/18/03  pbrown    Add a couple overlooked contributors.

    40    03/03/03  pbrown    Fixed list of immediate-mode VertexAttrib
                              functions in Section 2.7 -- there are no
                              normalized float functions (e.g.,
                              VertexAttrib4Nfv).  Clarified issue (42)
                              describing how point size is handled in vertex
                              program mode.

    39    01/31/03  pbrown    Fixed minor bug in the description of vertex
                              array state kept by the GL -- normalization
                              flags were omitted from the text (but were in
                              the state tables).

    38    01/08/03  pbrown    Fixed bug where "state.matrix.mvp" was specified
                              incorrectly -- it should be P*M0 rather than
                              M0*P.

    37    12/23/02  pbrown    Fixed minor typos.  Fixed state table bug where
                              CURRENT_VERTEX_ATTRIB_ARB was incorrectly called
                              CURRENT_ATTRIB_ARB.

    36    09/09/02  pbrown    Fixed incorrect example of matrix row bindings
                              (and transposition).  Small wording/typo fixes.

    35    08/27/02  pbrown    Fixed several minor typos.  Documented that a
                              program string should not include a null
                              terminator in its first <len> characters.  Fixed
                              dangling reference in <paramMultipleItem>
                              grammar rule.  Fix incorrect wording in
                              computation of state.light.half vector.
                              Documented that the inverse of a singular matrix
                              is undefined.  Clarified that native
                              instructions can include additions due to
                              emulation of features not supported natively.
                              Documented that LG2 produces undefined results
                              with zero or negative inputs.  Clarified that
                              POW may be a LOG/MUL/EXP sequence, but isn't
                              necessarily so.  Disallowed multiple modelview
                              matrix syntax if ARB_vertex_blend or
                              EXT_vertex_weighting is unsupported.  Fixed
                              state table query function for attribute array
                              enables.  Added missing state table entry for
                              PROGRAM_UNDER_NATIVE_LIMITS_ARB.

    34    07/19/02  pbrown    Fixed typo in ArrayElement pseudo-code.

    33    07/17/02  pbrown    Fixed bug in the <stateLModProperty> grammar
                              rule.  Fixed documentation to indicate that
                              Enable/DisableVertexAttribArray are not display
                              listable.

    31    07/15/02  pbrown    Fixed <SWZ_instruction> grammar rule to match
                              the spec language -- base operand negation
                              doesn't apply, since you can independently
                              negate components.  Modified "XPD" instruction
```

```
                          to eliminate the implicit masking of the "w"
                          component; slight efficiency gain for some SW
                          implementations.  Modified "scenecolor" binding
                          to pass the diffuse alpha instead of the ambient
                          alpha; the former is more useful.

    30    07/02/02  pbrown    Minor wording fixes.

    29    06/21/02  pbrown    Mostly minor bug fixes from reviewer feedback;
                              also added one new item approved at ARB meeting.

                              Additions:  Added a "lightmodel.*.scenecolor"
                              holding lit color containing the composite
                              lighting result ignoring individual lights --
                              i.e., from only emissive materials and the light
                              model.  Added GLX protocol.

                              Minor changes:  Numerous minor typo and wording
                              fixes.  Added missing vertex array types to
                              vertex array size/type/normalized table.  Added
                              missing description of ambient light model color
                              binding.  Removed several references to language
                              features long since deleted.  Documented that
                              POW is not necessarily implemented as
                              LOG/MUL/EXP.  Fixed a couple minor errata in the
                              EXT_vertex_shader interaction section.  Added a
                              list of reserved keywords.

    28    06/16/02  pbrown    Minor updates based on feedback given on
                              versions 26 and 27.

                              Additions:  Added section on EXT_vertex_shader
                              interaction, provided by ATI.

                              Minor changes:  Minor grammar and readability
                              fixes.  Fixed several incomplete definitions.
                              Removed "GL" and "gl" prefixes from several
                              enumerants and function names to match spec
                              conventions.  Clarified the precision issue on
                              EX2/LG2.  Added missing functions that take
                              VERTEX_PROGRAM_ARB.  Clarified component
                              normalization on vertex arrays.  Clarified
                              clipping section to note that user clipping is
                              done with position invariant programs.
                              Clarified the handling of program zero in
                              BindProgramARB.  Fixed a couple incorrect
                              grammar rules.  Fixed incorrect grammar
                              references in description of vertex program
                              parameter array accesses.  Documented that the
                              SWZ instruction doesn't take "normal" swizzle
                              and negation modifiers, since it already has
                              some.  Clarified some NV_vertex_program
                              interactions.

    27    06/07/02  pbrown    Minor update based on ARB_vertex_program sample
                              implementation work.
```

```
                            Changes:  Changed fog coordinate attribute and
                            result binding name to "fogcoord" (was "fog").
                            Rearranged grammar based on sample
                            implementation verification.  There might be a
                            minor fix or two stuck in there.

      26    06/04/02  pbrown    Spec checkpoint published on the working group
                            web site.  Resolves most of the remaining open
                            issues.

                            Deletions:  Removed the ability to bind the
                            color matrix (from ARB_imaging).

                            Changes:  Resolved the handling of vertex
                            attribute zero (it always specifies a vertex, in
                            program mode or not).  Resolved the handling of
                            generic and conventional vertex attribute arrays
                            (they are always sent, although they also have
                            "undefined aliasing" behavior).  Default values
                            of generic attributes are undefined, to
                            accommodate aliasing and non-aliasing
                            implementations.  Added pseudocode to document
                            the processing of ArrayElement.  Moved program
                            object language into the vertex program section.
                            Renamed the fog coordinate attribute and result
                            binding to "fogcoord".  Added missing
                            documentation of the agreed-upon semantic
                            restriction that programs can't bind
                            conventional / generic attribute pairs that may
                            alias.  Added documentation of what happens when
                            multiple contexts share program objects
                            Disallowed queries of generic attribute zero.

                            Fixes:  Fixed prototype for VertexAttrib4Nub.

                            Minor Changes:  Minor typo and language
                            fixes. Added guidelines for future
                            programmability extensions.  Added several
                            missing grammar rules.

      25    05/30/02  pbrown    Spec checkpoint published on the working group
                            web site.

                            Additions:  Add "DPH" (dot product homogeneous)
                            instruction.  Added the ability to query the
                            current matrix in transposed form.  Assigned
                            enumerant values for program matrices.  Added
                            the ability bind selected rows of a matrix.
                            Added ability to bind matrix palette matrices.

                            Changes:  Renamed PROGRAM_NAME_ARB to
                            PROGRAM_BINDING_ARB.  Specifying the number of
                            elements in parameter arrays is now optional,
                            but compilation will fail if the specified count
                            does not match.  Programs performing
                            out-of-bounds array accesses using absolute
                            addressing will now fail to load.  Allow "$" in
```

```
                                 token names.

                                 Minor changes:  Completed scrub of the issues
                                 and error list.  Added new issues about reserved
                                 keywords, identifier characters, and parsing of
                                 floating-point constants in programs.
                                 Miscellaneous typo fixes.  Updated the grammar
                                 to include light products and half angles, moved
                                 material properties from per-vertex to parameter
                                 bindings, and a few other miscellaneous fixes.
                                 Simplified the matrix binding table.  Modified
                                 the color sum portion of the spec to explicitly
                                 add R,G,B only.  Removed several incorrect
                                 errors.  Fixed program object state table.

    24    05/21/02  pbrown    Spec checkpoint published on the working group
                                 web site.

                                 Deletions:  Removed the semantic requirement
                                 that vertex programs write a vertex position,
                                 per working group resolution.

                                 Minor changes:  Cleaned up cruft in a number of
                                 issues; many more to go.  Added several issues.
                                 Documented that VertexAttrib functions are
                                 allowed inside Begin/End pairs.  Changed default
                                 initialization values of generic attributes to
                                 accommodate attribute aliasing.  Documented that
                                 point sizes and fog coordinates computed by
                                 vertex programs are clipped during primitive
                                 clipping.  Documented that vertex program
                                 behavior is undefined in color index mode.

    23    05/21/02  pbrown    Spec checkpoint.  More changes from working
                                 group deliberations.

                                 Additions:  Added vertex materials as allowed
                                 program parameter bindings.  Allow programs to
                                 use vertex attribute binding names, program
                                 parameter binding names, result variable binding
                                 names, and constants in executable statements,
                                 resulting in implicit bindings.  Added support
                                 for binding a single row of a matrix.  Added
                                 support for binding precomputed light/material
                                 products.  Added restriction that a single GL
                                 state vector can't be bound multiple times in
                                 two separate arrays accessed with relative
                                 addressing.  Added new section documenting the
                                 various resource limits, and introducting the
                                 idea of "native" resource limits and counts.

                                 Deletions:  Removed vertex materials as allowed
                                 vertex attribute bindings.

                                 Minor changes:  Added more names to the
                                 contributors list.  Updated issues concerning
                                 undefined aliasing.  Moved NV_vertex_program
```

```
                          related issues to the NV_vertex_program
                          interaction sections.  Updated NV_vertex_program
                          interactions.  Updated lighting example using
                          new derived state bindings.  Clarified that
                          "!!ARBvp1.0" is not a token in the grammar and
                          that programs are parsed beginning immediately
                          after the header string.  Added text to explain
                          all attribute, program parameter, and result
                          bindings instead of depending on binding table
                          interpretations.  Broke the large program
                          parameter binding table into several smaller
                          tables, organized by function.  Documented that
                          the queryable program error string may contain
                          warnings when a program loads successfully, and
                          that a queried program error string is
                          guaranteed to remain constant only until the
                          next program load attempt.  Added PROGRAM_NAME
                          query to the appropriate state table.

      22    05/20/02  pbrown    Spec checkpoint.  More changes from working
                          group deliberations.

                          Added functionality:  Assigned enumerant values.
                          Added "undefined (vertex attribute) aliasing"
                          language, where setting a generic attribute
                          leaves a conventional one undefined, and vice
                          versa.  Added support for matrix indices from
                          ARB_matrix_palette.  Added default program
                          object zero.  Added support for simple named
                          variable aliasing.  Added queries of API-level
                          and "native" resources used by a program and
                          their corresponding limits.  Added general query
                          to determine if a program fits in native limits.

                          Removed functionality:  Removed extension string
                          entry for position-invariant programs (now
                          mandatory).

                          Modified functionality:  GetProgram and
                          GetProgramString now take a target instead of a
                          program name.  Default values for 3 generic
                          attributes are changed for consistent aliasing.
                          Added 1/(end-start) binding for fog parameters.
                          Added precomputed infinite light/viewer half
                          angle binding.  ProgramString takes a "void *"
                          instead of a "ubyte *".

                          Minor Changes:  Clarified key terms for the
                          extension.  Documented that user clipping is not
                          supported in the base extension.  Added warnings
                          on a couple pitfalls from uninitalized result
                          registers.  Document that EXT_vertex_weighting
                          and ARB_vertex_blend use the same weight.
                          Cleaned up bindings for 4-component colors for
                          cases where only three components are used.
                          Documented the implicit absolute value operation
                          on the LOG instruction.  Renamed query token for
```

```
                                querying generic vertex attribute array enables.
                                Renamed and relocated vertex program binding
                                query.  Added language to Section 2.6.  Changed
                                syntax to bind a range of the environment or
                                local paramater array to use double dots ("..").
                                Clarified what happens on a weight binding using
                                more weights than an implementation supports.
                                Clarified the component selection pseudocode for
                                scalar operand loads.  Clarified what happens to
                                vertex program results during primitive
                                assembly.  Fixed a number of errors in the state
                                tables.

    21    04/29/02  pbrown    More changes from working group deliberations.

                                Added functionality:  Added "FLR", "FRC", "POW",
                                and "XPD" (cross product) instructions.  Added
                                functions to enable/disable generic attribute
                                arrays.  Added query of a program error string.
                                Added "format" enum argument to ProgramStringARB
                                to provide for possible programs not using ASCII
                                text.  Added new enums to permit different
                                limits for overall numbers of program
                                environment and local parameters and the number
                                of parameters that can be bound by a program.

                                Removed functionality:  Removed support for
                                evaluators for generic attributes.  Removed
                                support for program residency management.
                                Removed support for user clipping in standard
                                vertex programs.  Removed functionality to set
                                more than one program environment parameter at
                                once.

                                Issues/Changes:  Resolved set of immediate mode
                                VertexAttrib functions.  Combined parameter
                                bindings for several groups of related GL state.
                                Resolved user clipping issue by disallowing
                                except for position invariant programs.
                                Resolved limits for array relative offsets.
                                GenProgramsARB and DeleteProgramsARB will use
                                texture object model.  Program environment
                                parameters will not be pushed/popped.

                                Bug fixes:  Fixed vertex attribute index
                                prototypes (should be uint instead of int).
                                Fixed tokens used to query generic attribute
                                state (should have VERTEX prefixes).  Fixed
                                documentation of the alpha component of material
                                colors.  Fixed documentation of initial state
                                for vertex program objects.

                                Temporarily removed dated GLX protocol language
                                (will restore in one pass after resolving
                                remaining issues).

    20    04/17/02  pbrown    Clarify the meaning of individual components of
```

```
                            program parameters where the component mapping
                            is not obvious from the mapping table.

  18    04/15/02  pbrown    Update spec to reflect issues resolved by the
                            working group on 4/11.

                            Started using "program matrix" terminology --
                            was "tracking matrix".

                            Address register variables must now be declared.
                            The number of address registers can be queried.
                            Only 1-component address registers are currently
                            supported.

                            VertexAttribPointer takes a separate argument to
                            indicate normalized data, now called
                            "normalized" (was "normalize").

                            ProgramString and functions to set and query
                            local parameters all take a <target> and refer
                            to the currently bound program (previously took
                            a program number).  Have not touched other
                            somewhat related issues (e.g., is there a
                            program object zero?).

                            Added COLOR_SUM enable (taken directly from
                            EXT_secondary_color) for completeness and a
                            few updates to EXT_secondary_color
                            interactions.

                            Fixed cut-and-paste error in specification of
                            the clip-space user clip dot product.

                            Documented special-case arithmetic for ADD, MAD,
                            and MUL.

                            Eliminated some wordiness in DP3 and DP4
                            instruction pseudo-code.

                            Minor changes not from working group:  More
                            verbose documentation on the user clipping
                            issue.  More detail on other opcode candidates.
                            Removed redundant color material issue.  Minor
                            fixes to error roundup (not complete) and to
                            state tables to reflect that most program
                            execution variables are initially undefined.

  17    04/08/02  pbrown    Issues:  Enumerated other candidates for
                            consideration in the instruction set -- there
                            may be more that I missed.  Added a description
                            of some of the considerations on how color
                            material should be treated.  Added issues on the
                            name of the program matrices, the number of MVP
                            matrices, and where variable declarations
                            can be done.  Added numbers to all spec issues.
                            Fixed lighting example (issue 74) so it
                            compiles, and so that the half vector is
```

```
                                properly normalized.

                                Grammar:  Eliminated stale hardwired temporary,
                                parameter array, and result register names
                                (R<n>, c[<n>], and o[...]).  Should have been
                                deleted going from revision 5 to revision 12.
                                Added missing program matrix bindings to the
                                grammar.  Eliminated state material-as-parameter
                                bindings.  Fixed texgen paramete bindings, which
                                should have had both "eye" and "object" planes.
                                Added separate address register write masks and
                                selectors to reflect the current single-
                                component address register restriction.  Added
                                an array[A0.x] rule -- before, you erroneously
                                had to add or subtract a constant.  Modified SWZ
                                so that the register being swizzled can't take a
                                conventional swizzle suffix, too.

                                Also reorganized grammar to closely mirror the
                                sample implementation, consolidating a number of
                                redundant rules.  Also fixed several bugs
                                found by the implementation.

                                Documentation changes to "LIT" to use the right
                                variable name and also indicate that 0^0=1.
                                Fixed the computation of result.y in the "LOG"
                                instruction.

                                Other:  Added dependency on ARB_imaging.  Added
                                notation of Microsoft's IP claims.  Fixed name
                                of MAX_VERTEX_PROGRAM_TEMPORARIES_ARB.

                                A few minor typo fixes.

    12    03/11/02  pbrown    Modified spec to reflect decisions made at
                                the March 2002 ARB meeting.  Distributed
                                to the OpenGL participants list.

    5     03/03/02  pbrown    Distributed to the ARB prior to March 2002
                                ARB meeting.
```

Name

    ARB_window_pos

Name Strings

    GL_ARB_window_pos

Status

    Complete. Approved by ARB on February 14, 2002.

Version

    Last Modified Date: June 11, 2002

Number

    ARB Extension #25

Dependencies

    OpenGL 1.0 is required.
    The extension is written against the OpenGL 1.3 Specification
    GL_EXT_fog_coordinate effects the definition of this extension.
    GL_EXT_secondary_color effects the definition of this extension.

Overview

In order to set the current raster position to a specific window coordinate with the RasterPos command, the modelview matrix, projection matrix and viewport must be set very carefully. Furthermore, if the desired window coordinate is outside of the window's bounds one must rely on a subtle side-effect of the Bitmap command in order to avoid frustum clipping.

This extension provides a set of functions to directly set the current raster position in window coordinates, bypassing the modelview matrix, the projection matrix and the viewport-to-window mapping. Furthermore, clip testing is not performed, so that the current raster position is always valid.

This greatly simplifies the process of setting the current raster position to a specific window coordinate prior to calling DrawPixels, CopyPixels or Bitmap. Many matrix operations can be avoided when mixing 2D and 3D rendering.

IP Status

No IP issues.

Issues

(1) Should we offer all 24 entrypoints, just like glRasterPos?

RESOLVED. No. Don't implement the 4-coordinate functions as they're really useless. However, we will implement the short and double-type functions for completeness.

For example, it's conceivable that an application may have data structures encoding window coordinates as a 2- or 3-vector of shorts and will want to use WindowPos3svARB(). Chris Hecker lobbied for this on the grounds of orthogonality.

(2) Should we have unique GLX protocol requests for every entrypoint or just a 3-float version?

RESOLVED. Just a 3-float version will suffice since all reasonable window coordinate values can be perfectly represented with single-precision floating point.

*(4) For WindowPos2*ARB(), is zero the correct value for z? Afterall, z is a window coordinate, not an object coordinate.*

RESOLVED. Yes, zero is correct. Zero corresponds to the front of the depth range. That's where one would usually want Bitmap, DrawPixels and CopyPixels to be positioned in z when rendering 2D primitives over a 3D scene.

(5) What about glDepthRange?

RESOLVED. Map the WindowPos z value into the range specified by DepthRange. There's a popular optimization used to avoid depth buffer clears for scenes that completely fill the window in which the depth buffer is effectively halfed and reversed in alternate frames by calling DepthRange. The WindowPos z value should be subjected to depth range mapping so that it will work with this optimization, and in other scenarios.

(6) Should we mention EXT_fog_coord and EXT_secondary_color in this extension?

RESOLVED. Yes, otherwise implementors may not know what to do with them. It's been suggested that we instead go back and update the EXT_fog_coordinate and EXT_secondary_color specifications with respect to ARB_window_pos instead. However, that seems unlikely to happen and seems error-prone/obscure for implementors.

(7) What about the raster fog coordinate?

RESOLVED. If EXT_fog_coord is not supported, CURRENT_RASTER_DISTANCE is set to zero.

If EXT_fog_coord is supported, the behavior is dependent on the current state of FOG_COORDINATE_SOURCE_EXT. If the fog coordinate source is FRAGMENT_DEPTH_EXT, CURRENT_RASTER_DISTANCE is set to zero. If the fog coordinate source is FOG_COORDINATE_EXT, CURRENT_RASTER_DISTANCE is set to the current fog coordinate.

The value chosen for CURRENT_RASTER_DISTANCE state matches the value that would be chosen for normal vertices, except that WindowPos does not allow the GL to compute eye coordinates that would be used to generate a fog distance value. Instead, a value of zero is always used as a fog distance.

With the current EXT_fog_coord specification, there are two pieces of RasterPos state that drive fog (CURRENT_RASTER_DISTANCE and the current raster fog coordinate). The setting of the fog coordinate source selects which piece of state is used at rasterization (Bitmap, DrawPixels) time. Instead, this extension moves the selection of fog state to RasterPos state computation instead of rasterization and combines the two pieces of state into a single CURRENT_RASTER_DISTANCE.

Current implementations of EXT_fog_coord that support two pieces of state can either change the implementations to merge the two pieces into a single state or contiue to maintain two pieces of state. If the implementations continue to maintain two pieces of state, both the CURRENT_RASTER_DISTANCE and current raster fog coordinate are set to the same value.

(8) What about the secondary raster color?

RESOLVED. If EXT_secondary_color is supported, the (unnamed) current raster secondary color is set by taking the current secondary color and clamping the components to the range [0,1].

If EXT_secondary_color is not supported, the current raster secondary color is set to (0,0,0).

(9) How is this extension specification different from the MESA_window_pos extension?

(a) Clarified that lighting and texgen aren't used when updating the current raster state.

(b) Explicitly state the effect on CURRENT_RASTER_DISTANCE and CURRENT_RASTER_POSITION_VALID.

(c) Explain how the raster position's secondary color and fog coordinate are handled.

(d) Z is mapped according to the DEPTH_RANGE values.

(e) Removed the functions which take 4 coordinates.

New Procedures and Functions

```
    void WindowPos2dARB(double x, double y)
    void WindowPos2fARB(float x, float y)
    void WindowPos2iARB(int x, int y)
    void WindowPos2sARB(short x, short y)
    void WindowPos2dvARB(const double *p)
    void WindowPos2fvARB(const float *p)
    void WindowPos2ivARB(const int *p)
    void WindowPos2svARB(const short *p)

    void WindowPos3dARB(double x, double y, double z)
    void WindowPos3fARB(float x, float y, float z)
    void WindowPos3iARB(int x, int y, int z)
    void WindowPos3sARB(short x, short y, short z)

    void WindowPos3dvARB(const double *p)
    void WindowPos3fvARB(const float *p)
    void WindowPos3ivARB(const int *p)
    void WindowPos3svARB(const short *p)
```

New Tokens

none

Additions to Chapter 2 of the OpenGL 1.3 Specification (OpenGL Operation)

In **section 2.12 (Current Raster Position)**, p. 42, insert after fifth paragraph:

Alternately, the current raster position may be set by one of the WindowPosARB commands:

```
   void WindowPos{23}{ifds}ARB( T coords );
   void WindowPos{23}{ifds}vARB( const T coords );
```

WindosPos3ARB takes three values indicating x, y and z while WindowPos2ARB takes two values indicating x and y with z implicitly set to 0.

The CURRENT_RASTER_POSITION, (RPx, RPy, RPz, RPw), is updated as follows:

```
    RPx = x

    RPy = y

          { n,                  if z <= 0
    RPz = { f,                  if z >= 1
          { n + z * (f - n),   otherwise

    RPw = 1
```

where <n> is the DEPTH_RANGE's near value, and <f> is the DEPTH_RANGE's far value.

In RGBA mode, CURRENT_RASTER_COLOR is updated from CURRENT_COLOR with each color component clamped to the range [0,1].

In color index mode, CURRENT_RASTER_INDEX is updated from CURRENT_INDEX.

```
        All sets of CURRENT_RASTER_TEXTURE_COORDS are updated from
        the corresponding CURRENT_TEXTURE_COORDS sets.

        CURRENT_RASTER_POSITION_VALID is set to TRUE.

        If EXT_fog_coord is not supported.

          CURRENT_RASTER_DISTANCE is set to zero.

        If EXT_fog_coord is supported:

          CURRENT_RASTER_DISTANCE is set to

            { CURRENT_FOG_COORDINATE, if FOG_COORDINATE_SOURCE_EXT is set
            {                           to FOG_COORDINATE_EXT, or
            { 0,                      if FOG_COORDINATE_SOURCE_EXT is set
            {                           to FRAGMENT_DEPTH_EXT.

        If EXT_secondary_color is supported:

          The current raster secondary color is set by clamping the components
          of CURRENT_SECONDARY_COLOR_EXT to [0,1], if in RGBA mode.

        If EXT_secondary_color is not supported:

         The current raster secondary color (the secondary color used for all
         pixel and bitmap rasterization) is set to (0,0,0), if in RGBA mode.

        Note that lighting, texture coordinate generation, and clipping are
        not performed by the WindowPos*ARB functions.
```

Additions to Chapter 5 of the OpenGL 1.3 Specification (Special Functions)

In **section 5.2 (Selection)**, p. 188, modify the fourth paragraph to read:

```
        In selection mode, if a point, line, polygon, or the valid
        coordinates produced by a RasterPos command intersects the clip
        volume (section 2.11) then this primitive (or RasterPos command)
        causes a selection hit.  WindowPos commands always generate a
        selection hit since the resulting raster position is always
        valid.  In the case of polygons (...)
```

Additions to the AGL/GLX/WGL Specifications

None

GLX Protocol

One new GL rendering command is added. The following command is sent to the server as part of a glXRender request:

```
        WindowPosARB
            2           16              rendering command length
            2           230             rendering command opcode
            4           FLOAT32         x
            4           FLOAT32         y
            4           FLOAT32         z
```

Errors

    INVALID_OPERATION is generated if WindowPosARB is called betweeen
    Begin and End.

New State

    None.

New Implementation Dependent State

    None.

Revision History

```
    May 17, 2001
        - Initial version based on GL_MESA_window_pos extension
    May 22, 2001
        - Explicitly state that x, y, z are window coordinates and w is
          a clip space coordinate.  (Dan Brokenshire)
    May 23, 2001
        - Resolved issues 1 and 2.
        - Added issues 4 and 5.
    May 24, 2001
        - Rewrote body of specification to more clearly indicate how all
          raster position state is updated by WindowPos.
        - Updated the issues section.
    Jun 13, 2001
        - Added back the double and short versions of WindowPos()
        - Added fog coord issue and discusstion.
        - Reordered/renumbered the issues section.
    Jun 22, 2001
        - Set raster secondary color to current secondary color, not black
    Jun 25, 2001
        - Another change to secondary color, think I got it now!
    Nov 16, 2001
        - updated email address
        - List options "A" and "B" to determine behaviour of current raster
          fog coordinate.
    Nov 17, 2001
        - minor clean-ups
    Dec 12, 2001
        - rewrite against the OpenGL 1.3 spec
        - fixed a few typos
    Jan 10, 2002
        - update the interaction with EXT_fog_coord and EXT_secondary_color
          based on the proposed resolution from the December 2001 ARB
          meeting. (Pat Brown)
    Jan 18, 2002
        - Merges two pieces of fog state into a single state. (Bimal Poddar)
    Mar 12, 2002
        - Added GLX protocol. (Jon Leech)
    June 11, 2002
        - Clarifications: RGBA/index color updates apply only in
          RGBA/index mode respectively. Hits are generated in selection mode.

Name

    ATI_draw_buffers

Name Strings

    GL_ATI_draw_buffers

Status

    Complete.

Version

    Last Modified Date: December 30, 2002
    Revision: 8

Number

    277

Dependencies

    The extension is written against the OpenGL 1.3 Specification.

    OpenGL 1.3 is required.

    ARB_fragment_program affects the definition of this extension.

Overview

    This extension extends ARB_fragment_program to allow multiple output
    colors, and provides a mechanism for directing those outputs to
    multiple color buffers.

Issues

    (1) How many GL_DRAW_BUFFER#_ATI enums should be reserved?

      RESOLVED: We only need 4 currently, but for future expandability
      it would be nice to keep the enums in sequence. We'll specify
      16 for now, which will be more than enough for a long time.

New Procedures and Functions

    void DrawBuffersATI(sizei n, const enum *bufs);

New Tokens

    Accepted by the <pname> parameters of GetIntegerv, GetFloatv,
    and GetDoublev:

MAX_DRAW_BUFFERS_ATI	0x8824
DRAW_BUFFER0_ATI	0x8825
DRAW_BUFFER1_ATI	0x8826
DRAW_BUFFER2_ATI	0x8827
DRAW_BUFFER3_ATI	0x8828
DRAW_BUFFER4_ATI	0x8829
DRAW_BUFFER5_ATI	0x882A
DRAW_BUFFER6_ATI	0x882B
DRAW_BUFFER7_ATI	0x882C
DRAW_BUFFER8_ATI	0x882D
DRAW_BUFFER9_ATI	0x882E
DRAW_BUFFER10_ATI	0x882F
DRAW_BUFFER11_ATI	0x8830
DRAW_BUFFER12_ATI	0x8831
DRAW_BUFFER13_ATI	0x8832
DRAW_BUFFER14_ATI	0x8833
DRAW_BUFFER15_ATI	0x8834

Additions to Chapter 2 of the OpenGL 1.3 Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the OpenGL 1.3 Specification (Rasterization)

Modify Section 3.11.2, Fragment Program Grammar and Semantic Restrictions

    (replace <resultBinding> grammar rule with these rules)

```
<resultBinding>        ::= "result" "." "color" <optOutputColorNum>
                         | "result" "." "depth"

<optOutputColorNum>    ::= ""
                         | "[" <outputColorNum> "]"

<outputColorNum>       ::= <integer> from 0 to MAX_DRAW_BUFFERS_ATI-1
```

Modify Section 3.11.3.4, Fragment Program Results

    (modify Table X.3)

Binding	Components	Description
result.color[n]	(r,g,b,a)	color n
result.depth	(*,*,*,d)	depth coordinate

Table X.3: Fragment Result Variable Bindings. Components labeled "*" are unused. "[n]" is optional -- color <n> is used if specified; color 0 is used otherwise.

(modify third paragraph) If a result variable binding matches "result.color[n]", updates to the "x", "y", "z", and "w" components of the result variable modify the "r", "g", "b", and "a" components, respectively, of the fragment's corresponding output color. If "result.color[n]" is not both bound by the fragment program and written by some instruction of the program, the output color <n> of the fragment program is undefined.

Add a new Section 3.11.4.5.3

3.11.4.5.3 Draw Buffers Program Option

If a fragment program specifies the "ATI_draw_buffers" option, it will generate multiple output colors, and the result binding "result.color[n]" is allowed, as described in section 3.11.3.4, and with modified grammar rules as set forth in section 3.11.2. If this option is not specified, a fragment program that attempts to bind "result.color[n]" will fail to load, and only "result.color" will be allowed.

Additions to Chapter 4 of the OpenGL 1.3 Specification (Per-Fragment Operations and the Frame Buffer)

Modify Section 4.2.1, Selecting a Buffer for Writing (p. 168)

(modify the title and first paragraph, p. 168)

4.2.1 Selecting Color Buffers for Writing

The first such operation is controlling the color buffers into which each of the output colors are written. This is accomplished with either DrawBuffer or DrawBuffersATI. DrawBuffer defines the set of color buffers to which output color 0 is written.

(insert paragraph between first and second paragraph, p. 168)

DrawBuffer will set the draw buffer for output colors other than 0 to NONE. DrawBuffersATI defines the draw buffers to which all output colors are written.

```
  void DrawBuffersATI(sizei n, const enum *bufs);
```

<n> specifies the number of buffers in <bufs>. <bufs> is a pointer to an array of symbolic constants specifying the buffer to which each output color is written. The constants may be NONE, FRONT_LEFT, FRONT_RIGHT, BACK_LEFT, BACK_RIGHT, and AUX0 through AUXn, where n + 1 is the number of available auxiliary buffers. The draw buffers being defined correspond in order to the respective output colors. The draw buffer for output colors beyond <n> is set to NONE.

If the "ATI_draw_buffers" fragment program option, is not being used then DrawBuffersATI specifies a set of draw buffers into which output color 0 is written.

The maximum number of draw buffers is implementation dependent and must be at least 1. The number of draw buffers supported can be queried with the state MAX_DRAW_BUFFERS_ATI.

The constants FRONT, BACK, LEFT, RIGHT, and FRONT_AND_BACK that refer to multiple buffers are not valid for use in DrawBuffersATI and will result in the error INVALID_OPERATION.

If DrawBuffersATI is supplied with a constant (other than NONE) that does not indicate any of the color buffers allocated to the GL context, the error INVALID_OPERATION will be generated. If <n> is greater than MAX_DRAW_BUFFERS_ATI, the error INVALID_OPERATION will be generated.

(replace last paragraph, p. 169)

The state required to handle color buffer selection is an integer for each supported output color. In the initial state, draw buffer for output color 0 is FRONT if there are no back buffers; otherwise it is BACK. The initial state of draw buffers for output colors other then 0 is NONE.

Additions to Chapter 5 of the OpenGL 1.3 Specification (Special Functions)

None

Additions to Chapter 6 of the OpenGL 1.3 Specification (State and State Requests)

None

Dependencies on ARB_fragment_program

If ARB_fragment_program is not supported then all changes to section 3.11 are removed.

Interactions with possible future extensions

If there is some other future extension that defines multiple color outputs then this extension and glDrawBuffersATI could be used to define the destinations for those outputs. This extension need not be used only with ARB_fragment_program.

Errors

The error INVALID_OPERATION is generated by DrawBuffersATI if a color buffer not currently allocated to the GL context is specified.

The error INVALID_OPERATION is generated by DrawBuffersATI if <n> is greater than the state MAX_DRAW_BUFFERS_ATI.

The error INVALID_OPERATION is generated by DrawBuffersATI if value in <bufs> does not correspond to one of the allowed buffers.

New State

    (table 6.19, p227) add the following entry:

Get Value	Type	Get Command	Initial Value	Description	Section	Attribute
DRAW_BUFFERi_ATI	Z10*	GetIntegerv	see 4.2.1	Draw buffer selected for output color i	4.2.1	color-buffer

New Implementation Dependent State

Get Value	Type	Get Command	Minimum Value	Description	Sec.	Attribute
MAX_DRAW_BUFFERS_ATI	Z+	GetIntegerv	1	Maximum number of active draw buffers	4.2.1	-

Revision History

```
   Date: 12/30/2002
   Revision: 8
      - Clarified that DrawBuffersATI will set the set of draw buffers to
        write color output 0 to when the "ATI_draw_buffer" fragments
        program option is not in use.

   Date: 9/27/2002
   Revision: 7
      - Fixed confusion between meaning of color buffer and draw buffer
        in last revision.
      - Fixed mistake in when an error is generated based on the <n>
        argument of DrawBuffersATI.

   Date: 9/26/2002
   Revision: 6
      - Cleaned up and put in sync with latest ARB_fragment_program
        revision (#22).  Some meaningless changes made just in the name
        of consistency.

   Date: 9/11/2002
   Revision: 5
      - Added section 3.11.4.5.3.
      - Added enum numbers to New Tokens.

   Date: 9/9/2002
   Revision: 4
      - Changed error from MAX_OUTPUT_COLORS to MAX_DRAW_BUFFERS_ATI.
      - Changed 3.10 section numbers to 3.11 to match change to
        ARB_fragment_program spec.
      - Changed ARB_fragment_program from required to affects, and
        added section on interactions with it and future extensions
        that define multiple color outputs.

   Date: 9/6/2002
   Revision: 3
      - Changed error to INVALID OPERATION.
      - Cleaned up typos.
```

```
    Date: 8/19/2002
    Revision: 2
       - Added a paragraph that specifically points out that the
         constants that refer to multiple buffers are not allowed with
         DrawBuffersATI.
       - Changed bufs to <bufs> in a couple of places.

    Date: 8/16/2002
    Revision: 1
       - First draft for circulation.
```

Name

    ATI_texture_float

Name Strings

    GL_ATI_texture_float

Status

    Complete.

Version

    Last Modified Date: December 4, 2002
    Revision: 4

Number

    280

Dependencies

    OpenGL 1.1 or EXT_texture is required.

    The extension is written against the OpenGL 1.3 Specification.

Overview

    This extension adds texture internal formats with 32 and 16 bit
    floating-point components. The 32 bit floating-point components
    are in the standard IEEE float format. The 16 bit floating-point
    components have 1 sign bit, 5 exponent bits, and 10 mantissa bits.
    Floating-point components are clamped to the limits of the range
    representable by their format.

Issues

    1. *Should we expose a GL_FLOAT16_ATI pixel type so that the 16 bit*
       float textures can be directly loaded?

       RESOLUTION: This will be exposed in a separate extension.

New Procedures and Functions

   None

New Tokens

Accepted by the <internalFormat> parameter of TexImage1D, TexImage2D, and TexImage3D:

RGBA_FLOAT32_ATI	0x8814
RGB_FLOAT32_ATI	0x8815
ALPHA_FLOAT32_ATI	0x8816
INTENSITY_FLOAT32_ATI	0x8817
LUMINANCE_FLOAT32_ATI	0x8818
LUMINANCE_ALPHA_FLOAT32_ATI	0x8819
RGBA_FLOAT16_ATI	0x881A
RGB_FLOAT16_ATI	0x881B
ALPHA_FLOAT16_ATI	0x881C
INTENSITY_FLOAT16_ATI	0x881D
LUMINANCE_FLOAT16_ATI	0x881E
LUMINANCE_ALPHA_FLOAT16_ATI	0x881F

Additions to Chapter 2 of the OpenGL 1.3 Specification (OpenGL Operation)

Add a new Section 2.1.2, (p. 6):

2.1.2 16 Bit Floating-Point

A 16 bit floating-point number has 1 sign bit (s), 5 exponent bits (e), and 10 mantissa bits (m). The value (v) of a 16 bit floating-point number is determined by the following pseudo code:

```
if (e != 0)
    v = (-1)^s * 2^(e-15) * 1.m  # normalized
else if (f == 0)
    v = (-1)^s * 0               # zero
else
    v = (-1)^s * 2^(e-14) * 0.m  # denormalized
```

It is acceptable for an implementation to treat denormalized 16 bit floating-point numbers as zero.

There are no NAN or infinity values for 16 bit floating-point.

Additions to Chapter 3 of the OpenGL 1.3 Specification (Rasterization)

Section 3.8.1, (p. 116), change the last sentence on the page to:

Each R, G, B, and A value so generated is clamped based on the component type in the <internalFormat>. Fixed-point components are clamped to [0, 1]. Floating-point components are clamped to the limits of the range representable by their format. 32 bit floating- point components are in the standard IEEE float format. 16 bit floating-point components have 1 sign bit, 5 exponent bits, and 10 mantissa bits.

Section 3.8.1, (p. 119), add the following to table 3.16:

Sized Internal Format	Base Internal Format	R bits	G bits	B bits	A bits	L bits	I bits
RGBA_FLOAT32_ATI	RGBA	f32	f32	f32	f32		
RGB_FLOAT32_ATI	RGB	f32	f32	f32			
ALPHA_FLOAT32_ATI	ALPHA				f32		
INTENSITY_FLOAT32_ATI	INTENSITY						f32
LUMINANCE_FLOAT32_ATI	LUMINANCE					f32	
LUMINANCE_ALPHA_FLOAT32_ATI	LUMINANCE_ALPHA				f32	f32	
RGBA_FLOAT16_ATI	RGBA	f16	f16	f16	f16		
RGB_FLOAT16_ATI	RGB	f16	f16	f16			
ALPHA_FLOAT16_ATI	ALPHA				f16		
INTENSITY_FLOAT16_ATI	INTENSITY						f16
LUMINANCE_FLOAT16_ATI	LUMINANCE					f16	
LUMINANCE_ALPHA_FLOAT16_ATI	LUMINANCE_ALPHA				f16	f16

Name

    ATI_texture_mirror_once

Name Strings

    GL_ATI_texture_mirror_once

Version

    Last Modified Date: 11/14/2000 Revision: 0.30

Number

    221

Dependencies

    EXT_texture3D

Overview

    ATI_texture_mirror_once extends the set of texture wrap modes to
    include two modes (GL_MIRROR_CLAMP_ATI, GL_MIRROR_CLAMP_TO_EDGE_ATI)
    that effectively use a texture map twice as large as the original image
    in which the additional half of the new image is a mirror image of the
    original image.

    This new mode relaxes the need to generate images whose opposite edges
    match by using the original image to generate a matching "mirror image".
    This mode allows the texture to be mirrored only once in the negative
    s, t, and r directions.

Issues

    None known

New Procedure and Functions

    None

New Tokens

    Accepted by the <param> parameter of TexParameteri and TexParameterf,
    and by the <params> parameter of TexParameteriv and TexParameterfv, when
    their <pname> parameter is TEXTURE_WRAP_S, TEXTURE_WRAP_T, or
    TEXTURE_WRAP_R_EXT:

```
      MIRROR_CLAMP_ATI                     0x8742
      MIRROR_CLAMP_TO_EDGE_ATI             0x8743
```

Additions to Chapter 2 of the OpenGL 1.2.1 Specification (Operation)

    None

Additions to Chapter 3 if the OpenGL 1.2.1 Specification (Rasterization):

```
  - (3.8.3, p. 124) Change first three entries in table:

    "TEXTURE_WRAP_S     integer     CLAMP, CLAMP_TO_EDGE, REPEAT,
                                    MIRROR_CLAMP_ATI, MIRROR_CLAMP_TO_EDGE_ATI
     TEXTURE_WRAP_T     integer     CLAMP, CLAMP_TO_EDGE, REPEAT,
                                    MIRROR_CLAMP_ATI, MIRROR_CLAMP_TO_EDGE_ATI
     TEXTURE_WRAP_R     integer     CLAMP, CLAMP_TO_EDGE, REPEAT,
                                    MIRROR_CLAMP_ATI, MIRROR_CLAMP_TO_EDGE_ATI"

  - (3.8.4, p. 125) Added after second paragraph:

    "If TEXTURE_WRAP_S, TEXTURE_WRAP_T, or TEXTURE_WRAP_R_EXT is set to
     MIRROR_CLAMP_ATI or MIRROR_CLAMP_TO_EDGE_ATI, the s (or t or r)
     coordinate is clamped to [-1, 1] and then converted to:

         s      0  <= s <= 1
        -s     -1  <= s <  0

     Like the CLAMP wrap mode, with MIRROR_CLAMP_ATI the texels from
     the border can be used by the texture filter.  MIRROR_CLAMP_TO_EDGE_ATI
     clamps texture coordinates at all mipmap levels such that the texture
     filter never samples a border texel."

  - (3.8.5, p.127) Change last paragraph to:

    "When TEXTURE_MIN_FILTER is LINEAR, a 2 x 2 x 2 cube of texels in the
     image array of level TEXTURE_BASE_LEVEL is selected.  This cube is
     obtained by first clamping texture coordinates as described above
     under Texture Wrap Modes (if the wrap mode for a coordinate is CLAMP,
     CLAMP_TO_EDGE, MIRROR_CLAMP_ATI, or MIRROR_CLAMP_TO_EDGE_ATI) and
     computing..."

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the GL Specification (Rasterization)

One entry is added to table 3.5 (DrawPixels and ReadPixels formats). The new table is:

Name	Type	Elements	Target Buffer
COLOR_INDEX	Index	Color Index	Color
STENCIL_INDEX	Index	Stencil value	Stencil
DEPTH_COMPONENT	Component	Depth value	Depth
RED	Component	R	Color
GREEN	Component	G	Color
BLUE	Component	B	Color
ALPHA	Component	A	Color
RGB	Component	R, G, B	Color
RGBA	Component	R, G, B, A	Color
LUMINANCE	Component	Luminance value	Color
LUMINANCE_ALPHA	Component	Luminance value, A	Color
ABGR_EXT	Component	A, B, G, R	Color

Table 3.5: DrawPixels and ReadPixels formats. The third column gives a description of and the number and order of elements in a group.

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

The new format is added to the discussion of Obtaining Pixels from the Framebuffer. It should read " If the <format> is one of RED, GREEN, BLUE, ALPHA, RGB, RGBA, ABGR_EXT, LUMINANCE, or LUMINANCE_ALPHA, and the GL is in color index mode, then the color index is obtained."

The new format is added to the discussion of Index Lookup. It should read "If <format> is one of RED, GREEN, BLUE, ALPHA, RGB, RGBA, ABGR_EXT, LUMINANCE, or LUMINANCE_ALPHA, then the index is used to reference 4 tables of color components: PIXEL_MAP_I_TO_R, PIXEL_MAP_I_TO_G, PIXEL_MAP_I_TO_B, and PIXEL_MAP_I_TO_A."

Overview

EXT_bgra extends the list of host-memory color formats. Specifically, it provides formats which match the memory layout of Windows DIBs so that applications can use the same data in both Windows API calls and OpenGL pixel API calls.

New Procedures and Functions

None

New Tokens

Accepted by the <format> parameter of DrawPixels, GetTexImage, ReadPixels, TexImage1D, and TexImage2D:

```
    BGR_EXT                 0x80E0
    BGRA_EXT                0x80E1
```

Additions to Chapter 2 of the 1.1 Specification (OpenGL Operation)

None

Additions to Chapter 3 of the 1.1 Specification (Rasterization)

One entry is added to table 3.5 (DrawPixels and ReadPixels formats). The new table is:

Name	Type	Elements	Target Buffer
COLOR_INDEX	Index	Color Index	Color
STENCIL_INDEX	Index	Stencil value	Stencil
DEPTH_COMPONENT	Component	Depth value	Depth
RED	Component	R	Color
GREEN	Component	G	Color
BLUE	Component	B	Color
ALPHA	Component	A	Color

RGB	Component	R, G, B	Color
RGBA	Component	R, G, B, A	Color
LUMINANCE	Component	Luminance value	Color
LUMINANCE_ALPHA	Component	Luminance value, A	Color
BGR_EXT	Component	B, G, R	Color
BGRA_EXT	Component	B, G, R, A	Color

Table 3.5: DrawPixels and ReadPixels formats. The third column gives a description of and the number and order of elements in a group.

Additions to Chapter 4 of the 1.1 Specification (Per-Fragment Operations and the Framebuffer)

The new format is added to the discussion of Obtaining Pixels from the Framebuffer. It should read " If the <format> is one of RED, GREEN, BLUE, ALPHA, RGB, RGBA, BGR_EXT, BGRA_EXT, LUMINANCE, or LUMINANCE_ALPHA, and the GL is in color index mode, then the color index is obtained."

The new format is added to the discussion of Index Lookup. It should read "If <format> is one of RED, GREEN, BLUE, ALPHA, RGB, RGBA, BGR_EXT, BGRA_EXT, LUMINANCE, or LUMINANCE_ALPHA, then the index is used to reference 4 tables of color components: PIXEL_MAP_I_TO_R, PIXEL_MAP_I_TO_G, PIXEL_MAP_I_TO_B, and PIXEL_MAP_I_TO_A."

Dependencies

OpenGL 1.1 is required.

This extension is written against the OpenGL 2.0 specification and version 1.10.59 of the OpenGL Shading Language specification.

This extension interacts with GL_EXT_geometry_shader4.

Overview

This extension introduces the concept of bindable uniforms to the OpenGL Shading Language. A uniform variable can be declared bindable, which means that the storage for the uniform is not allocated by the compiler/linker anymore, but is backed by a buffer object. This buffer object is bound to the bindable uniform through the new command UniformBufferEXT(). Binding needs to happen after linking a program object.

Binding different buffer objects to a bindable uniform allows an application to easily use different "uniform data sets", without having to re-specify the data every time.

A buffer object can be bound to bindable uniforms in different program objects. If those bindable uniforms are all of the same type, accessing a bindable uniform in program object A will result in the same data if the same access is made in program object B. This provides a mechanism for 'environment uniforms', uniform values that can be shared among multiple program objects.

New Procedures and Functions

```
    void UniformBufferEXT(uint program, int location, uint buffer);
    int GetUniformBufferSizeEXT(uint program, int location);
    intptr GetUniformOffsetEXT(uint program, int location);
```

New Tokens

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
        MAX_VERTEX_BINDABLE_UNIFORMS_EXT                0x8DE2
        MAX_FRAGMENT_BINDABLE_UNIFORMS_EXT              0x8DE3
        MAX_GEOMETRY_BINDABLE_UNIFORMS_EXT              0x8DE4
        MAX_BINDABLE_UNIFORM_SIZE_EXT                   0x8DED
        UNIFORM_BUFFER_BINDING_EXT                      0x8DEF
```

Accepted by the <target> parameters of BindBuffer, BufferData, BufferSubData, MapBuffer, UnmapBuffer, GetBufferSubData, and GetBufferPointerv:

```
        UNIFORM_BUFFER_EXT                              0x8DEE
```

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

Modify section 2.15.3 "Shader Variables", page 75.

Add the following paragraph between the second and third paragraph on page 79, "Uniform Variables"

Uniform variables can be further characterized into bindable uniforms. Storage for bindable uniforms does not come out of the, potentially limited, uniform variable storage discussed in the previous paragraph. Instead, storage for a bindable uniform is provided by a buffer object that is bound to the uniform variable. Binding different buffer objects to a bindable uniform allows an application to easily use different "uniform data sets", without having to re-specify the data every time. A buffer object can be bound to bindable uniforms in different program objects. If those bindable uniforms are all of the same type, accessing a bindable uniform in program object A will result in the same data if the same access is made in program object B. This provides a mechanism for 'environment', uniform values that can be shared among multiple program objects.

Change the first sentence of the third paragraph, p. 79, as follows:

When a program object is successfully linked, all non-bindable active uniforms belonging to the program object are initialized to zero (FALSE for Booleans). All active bindable uniforms have their buffer object bindings reset to an invalid state. A successful link will also generate a location for each active uniform, including active bindable uniforms. The values of active uniforms can be changed using this location and the appropriate Uniform* command (see below). For bindable uniforms, a buffer object has to be first bound to the uniform before changing its value. These locations are invalidated.

Change the second to last paragraph, p. 79, as follows:

A valid name for a non-bindable uniform cannot be a structure, an array of structures, or any portion of a single vector or a matrix. A valid name for a bindable uniform cannot be any portion of a single vector or matrix. In order to identify a valid name, ...

Change the fifth paragraph, p. 81, as follows:

The given values are loaded into the uniform variable location identified by <location>. The parameter <location> cannot identify a bindable uniform structure or a bindable uniform array of structures. When loading data for a bindable uniform, the data will be stored in the appropriate location of the buffer object bound to the bindable uniform (see UniformBufferEXT below).

Add the following bullets to the list of errors on p. 82:

- If <location> refers to a bindable uniform structure or a bindable uniform array of structures.

- If <location> refers to a bindable uniform that has no buffer object bound to the uniform.

- If <location> refers to a bindable uniform and the bound buffer object is not of sufficient size. This means that the buffer object is smaller than the size that would be returned by GetUniformBufferSizeEXT for the bindable uniform.

- If <location> refers to a bindable uniform and the buffer object is bound to multiple bindable uniforms in the currently active program object.

Add a sub-section called "Bindable Uniforms" above the section "Samplers", p. 82:

The number of active bindable uniform variables that can be supported by a vertex shader is limited and specified by the implementation dependent constant MAX_VERTEX_BINDABLE_UNIFORMS_EXT. The minimum supported number of bindable uniforms is eight. A link error will be generated if the program object contains more active bindable uniform variables.

To query the minimum size needed for a buffer object to back a given bindable uniform, use the command:

```
  int GetUniformBufferSizeEXT(uint program, int location);
```

This command returns the size in basic machine units of the smallest buffer object that can be used for the bindable uniform given by <location>. The size returned is intended to be passed as the <size> parameter to the BufferData() command. The error INVALID_OPERATION will be generated if <location> does not correspond to an active bindable uniform in <program>. The parameter <location> has to be location corresponding to the name of the bindable uniform itself, otherwise the error INVALID_OPERATION is generated. If the bindable uniform is a structure, <location> can not refer to a structure member. If it is an array, <location> can not refer to any array member other than the first one. If

<program> has not been successfully linked, the error INVALID_OPERATION is generated.

There is an implementation-dependent limit on the size of bindable uniform variables. LinkProgram will fail if the storage required for the uniform (in basic machine units) exceeds MAX_BINDABLE_UNIFORM_SIZE_EXT.

To bind a buffer object to a bindable uniform, use the command:

```
  void UniformBufferEXT(uint program, int location, uint buffer)
```

This command binds the buffer object <buffer> to the bindable uniform <location> in the program object <program>. Any previous binding to the bindable uniform <location> is broken. Before calling UniformBufferEXT the buffer object has to be created, but it does not have to be initialized with data nor its size set. Passing the value zero in <buffer> will unbind the currently bound buffer object. The error INVALID_OPERATION is generated if <location> does not correspond to an active bindable uniform in <program>. The parameter <location> has to correspond to the name of the uniform variable itself, as described for GetUniformBufferSizeEXT, otherwise the error INVALID_OPERATION is generated. If <program> has not been successfully linked, or if <buffer> is not the name of an existing buffer object, the error INVALID_OPERATION is generated.

A buffer object cannot be bound to more than one uniform variable in any single program object. However, a buffer object can be bound to bindable uniform variables in multiple program objects. Furthermore, if those bindable uniforms are all of the same type, accessing a scalar, vector, a member of a structure, or an element of an array in program object A will result in the same data if the same scalar, vector, structure member, or array element is accessed in program object B. Additionally the structures in both program objects have to have the same members, specified in the same order, declared with the same data types and have the same name. If the buffer object bound to the uniform variable is smaller than the minimum size required to store the uniform variable, as reported by GetUniformbufferSizeEXT, the results of reading the variable (or any portion thereof) are undefined.

If LinkProgram is called on a program object that has already been linked, any buffer objects bound to the bindable uniforms in the program are unbound prior to linking, as though UniformBufferEXT were called for each bindable uniform with a <buffer> value of zero.

Buffer objects used to store uniform variables may be created and manipulated by buffer object functions (e.g., BufferData, BufferSubData, MapBuffer) by calling BindBuffer with a <target> of UNIFORM_BUFFER_EXT. It is not necessary to bind a buffer object to UNIFORM_BUFFER_EXT in order to use it with an active program object.

The size and layout of a bindable uniform variable in buffer object storage is not defined. However, the values of signed integer, unsigned integer, or floating-point uniforms may be updated by modifying the underying buffer object storage using either MapBuffer or BufferSubData. The command

```
  intptr GetUniformOffsetEXT(uint program, int location);
```

returns the offset (in bytes) of the uniform in <program> whose location returned by GetUniformLocation is <location>. The error INVALID_VALUE is generated if the object named by <program> does not exist. The error INVALID_OPERATION is generated if <program> is not a program object, if <program> was not linked successfully, or if <location> refers to a uniform that was not declared as bindable. The memory layout of matrix, boolean, or boolean vector uniforms is not defined, and the error INVALID_OPERATION will be generated if <location> refers to a boolean, boolean vector, or matrix uniform. The value -1 is returned by GetUniformOffsetEXT if an error is generated.

The values of such uniforms may be changing by writing signed integer, unsigned integer, or floating-point values into the buffer object at the byte offset returned by GetUniformOffsetEXT. For vectors, two to four integers or floating-point values should be written to consecutive locations in the buffer object storage. For arrays of scalar or vector variables, the number of bytes between individual array members is guaranteed to be constant, but array members are not guaranteed to be stored in adjacent locations. For example, some implementations may pad scalars, or two- or three-component vectors out to a four-component vector.

Change the first paragraph below the sub-heading 'Samplers', p. 82, as follows:

Samplers are special uniforms used in the OpenGL Shading Language to identify the texture object used for each texture lookup. Samplers cannot be declared as bindable in a shader. The value of a sampler indicates the texture image unit being accessed. Setting a sampler's value.

Add the following bullets to the list of error conditions for Begin on p. 87:

- There is one, or more, bindable uniform(s) in the currently active program object that does not have a buffer object bound to it.

- There is one, or more, bindable uniform(s) in the currently active program object that have a buffer object bound to it of insufficient size. This means that the buffer object is smaller than the size that would be returned by GetUniformBufferSizeEXT for the bindable uniform.

- A buffer object is bound to multiple bindable uniforms in the currently active program object.

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

Modify Section 3.11.1 "Shader Variables", p. 193

Add a paragraph between the first and second paragraph, p. 194

The number of active bindable uniform variables that can be supported by a fragment shader is limited and specified by the implementation dependent constant MAX_FRAGMENT_BINDABLE_UNIFORMS_EXT. The minimum supported number of bindable uniforms is eight. A link error will be generated if the program object contains more active bindable uniform variables.

Additions to Chapter 4 of the OpenGL 2.0 Specification (Per-Fragment Operations and the Frame Buffer)

None.

Additions to Chapter 5 of the OpenGL 2.0 Specification (Special Functions)

Change section 5.4 Display Lists, p. 237

Add the command UniformBufferEXT to the list of commands that are not compiled into a display list, but executed immediately, under "Program and Shader Objects", p. 241.

Additions to Chapter 6 of the OpenGL 2.0 Specification (State and State Requests)

None.

Additions to Appendix A of the OpenGL 2.0 Specification (Invariance)

None.

Additions to the AGL/GLX/WGL Specifications

None.

Interactions with GL_EXT_geometry_shader4

If GL_EXT_geometry_shader4 is supported, a geometry shader will also support bindable uniforms. The following paragraph needs to be added to the section that discusses geometry shaders:

"The number of active bindable uniform variables that can be supported by a geometry shader is limited and specified by the implementation dependent constant MAX_GEOMETRY_BINDABLE_UNIFORMS_EXT. The minimum supported number of bindable uniforms is eight. A link error will be generated if the program object contains more active bindable uniform variables."

The implementation dependent value MAX_GEOMETRY_BINDABLE_UNIFORMS_EXT will need to be added to the state tables and assigned an enum value.

Errors

The error INVALID_VALUE is generated by UniformBufferEXT, GetUniformBufferSize, or GetUniformOffsetEXT if <program> is not the name of a program or shader object.

The error INVALID_OPERATION is generated by UniformBufferEXT, GetUniformBufferSize, or GetUniformOffsetEXT if <program> is the name of a shader object.

The error INVALID_OPERATION is generated by the Uniform* commands if <location> refers to a bindable uniform structure or an array of such structures.

The error INVALID_OPERATION is generated by the Uniform* commands if

    <location> refers to a bindable uniform that has no buffer object bound.

    The error INVALID_OPERATION is generated by the Uniform* commands if
    <location> refers to a bindable uniform and the bound buffer object is not
    of sufficient size to store data into <location>.

    The error INVALID_OPERATION is generated by the GetUniformBufferSizeEXT
    and UniformBufferEXT commands if <program> has not been successfully
    linked.

    The error INVALID_OPERATION is generated by the GetUniformBufferSizeEXT
    and UniformBufferEXT commands if <location> is not the location
    corresponding to the name of the bindable uniform itself or if <location>
    does not correspond to an active bindable uniform in <program>.

    The error INVALID_OPERATION is generated by GetUniformOffsetEXT if
    <program> was not linked successfully, if <location> refers to a uniform
    that was not declared as bindable, or if <location> refers to a boolean,
    boolean vector, or matrix uniform.

    The error INVALID_OPERATION is generated by the UniformBufferEXT command if
    <buffer> is not the name of a buffer object.

    The error INVALID_OPERATION is generated by Begin, Rasterpos or any
    command that performs an implicit Begin if:

- A buffer object is bound to multiple bindable uniforms in the currently active program object.

- There is one, or more, bindable uniform(s) in the currently active program object that does not have a buffer object bound to it.

- There is one, or more, bindable uniform(s) in the currently active program object that have a buffer object bound to it of insufficient size. This means that the buffer object is smaller than the size that would be returned by GetUniformBufferSizeEXT for the bindable uniform.

New State

Get Value	Type	Get Command	Minimum Value	Description	Section	Attrib

UNIFORM_BUFFER_BINDING_EXT	Z+	GetIntegerv	0	Uniform buffer bound to the context for buffer object manipulation.	2.15	-

Modifications to The OpenGL Shading Language Specification, Version 1.10.59

Including the following line in a shader can be used to control the language features described in this extension:

```
#extension GL_EXT_bindable_uniform: <behavior>
```

where <behavior> is as specified in section 3.3.

A new preprocessor #define is added to the OpenGL Shading Language:

```
#define GL_EXT_bindable_uniform 1
```

Add to section 3.6 "Keywords"

Add the following keyword:

```
bindable
```

Change section 4.3 "Type Qualifiers"

In the qualifier table, add the following sub-qualifiers under the uniform qualifier:

```
bindable uniform
```

Change section 4.3.5 "Uniform"

Add the following paragraphs between the last and the second to last paragraphs:

Uniform variables, except for samplers, can optionally be further qualified with "bindable". If "bindable" is present, the storage for the uniform comes from a buffer object, which is bound to the uniform through the GL API, as described in section 2.15.3 of the OpenGL 2.0 specification. In this case, the memory used does not count against the storage limit described in the previous paragraph. When using the "bindable" keyword, it must immediately precede the "uniform" keyword.

An example bindable uniform declaration is:

```
bindable uniform float foo;
```

Only a limited number of uniforms can be bindable for each type of shader. If this limit is exceeded, it will cause a compile-time or link-time error. Bindable uniforms that are declared but not used do not count against this limit.

Add to section 9 "Shading Language Grammar"

```
type_qualifer:
   CONST
   ATTRIBUTE  // Vertex only
   uniform-modifieropt UNIFORM

uniform-modifier:
   BINDABLE
```

Issues

1. *Is binding a buffer object to a uniform done before or after linking a program object?*

   DISCUSSION: There is no need to re-link when changing the buffer object that backs a uniform. Re-binding can therefore be relatively quickly. Binding is be done using the location of the uniform retrieved by GetUniformLocation, to make it even faster (instead of binding by name of the uniform).

   Reasons to do this before linking: The linker might want to know what buffer object backs the uniform. Binding of a buffer object to a bindable uniform, in this case, will have to be done using the name of the uniform (no location is available until after linking). Changing the binding of a buffer object to a bindable uniform means the program object will have to be re-linked, which would substantially increase the overhead of using multiple different "constant sets" in a single program.

   RESOLUTION: Binding a buffer object to a bindable uniform needs to be done after the program object is linked. One of the purposes of this extension is to be able to switch among multiple sets of uniform values efficiently.

2. *Is the memory layout of a bindable uniform available to an application?*

   DISCUSSION: Buffer objects are arrays of bytes. The application can map a buffer object and retrieve a pointer to it, and read or write into it directly. Or, the application can use the BufferSubData() command to store data in a buffer object. They can also be filled using ReadPixels (with ARB_pixel_buffer_object), or filled using extensions such as the new transform feedback extension.

   If the layout of a uniform in buffer object memory is known, these different ways of filling a buffer object could be leveraged. On the other hand, different compiler implementations may want a different packing schemes that may or may not match an end-user's expectations (e.g., all individual uniforms might be stored as vec4's). If only the Uniform*() API were allowed to modify buffer objects, we could completely hide the layout of bindable uniforms. Unfortuantely, that would limit how the buffer object can be linked to other sources of data.

   RESOLUTION: RESOLVED. The memory layout of a bindable uniform variable will not be specified. However, a query function will be added that allows applications to determine the layout and load their buffer object via API's other than Uniform*() accordingly if they choose. Unfortunately, the layout may not be consistent across implementations of this extension.

Providing a better standard set of packing rules is highly desirable, and we hope to design and add such functionality in an extension in the near future.

3. *How is synchronization handled between a program object using a buffer object and updates to the buffer object?*

   DISCUSSION: For example, what happens when a ReadPixels into a buffer object is outstanding, that is bound to a bindable uniform while the program object, containing the bindable uniform, is in use?

   RESOLUTION: UNRESOLVED. It is probably the GL implementation's responsibility to properly synchronize such usages. This issue needs solving for GL_EXT_texture_buffer_object also, and should be consistent.

4. *A limited number of bindable uniforms can exist in one program object. Should this limit be queriable?*

   DISCUSSION: The link operation will fail if too many bindable uniforms are declared and active. Should the limit on the number of active bindable uniforms be queriable by the application?

   RESOLUTION: Yes, this limit is queriable.

5. *Is the limit discussed in the previous issue per shader type?*

   DISCUSSION: Is there a different limit for vertex shader and fragment shaders? Hardware might support different limits. The storage for uniform variables is a limit queriable per shader type, thus it would be nice to be consistent with the existing model.

   RESOLUTION: YES.

6. *Can an application find out programmatically that a uniform is declared as a bindable uniform?*

   DISCUSSION: Using GetActiveUniform() the application can programmatically find out which uniforms are active, what their type and size etc it. Do we need to add a mechanism for an application to find out if an active uniform is a bindable uniform?

   RESOLUTION: UNRESOLVED. To be consistent, the answer should be yes. However, extending GetActiveUniform() is not possible, which means we need a new API command. If we define a new API command, it probably is better to define something like: GetNewActiveUniform(int program, uint index, enum property, void *data); Or alternatively, define new API to query the properties of a uniform per uniform location: GetActiveUniformProperty(int program, int location, enum property, void *data)

7. *What to do when the buffer object bound to a bindable uniform is not big enough to back the uniform or if no buffer object is bound at all?*

DISCUSSION: The size of a buffer object can be changed, after it is bound, by calling BufferData. It is possible that the buffer object isn't sufficiently big enough to back the bindable uniform. This is an issue when loading values for uniforms and when actually rendering. In the case of loading uniforms, should the Uniform* API generate an error? In the case of rendering, should this be a Begin error?

RESOLUTION: RESOLVED. It is a Begin error if a buffer object is too small or no buffer object is bound at all. The Uniform* commands will generate an error in these cases as well.

8. *What restrictions are there on binding a buffer object to more than one bindable uniform?*

DISCUSSION: Can a buffer object be bound to more than one uniform within a program object? No, this does not seem to be a good idea. Can a buffer object be bound to more than one uniform in different program objects? Yes, this is useful functionality to have. If each uniform is also of the same type, then data access in program object A then the same access in program object B results in the same data. In the latter case, if the uniform variables are arrays, must the arrays have the same length declared? No, that is too big of a restriction. The application is responsible for making sure the buffer object is sufficiently sized to provide storage for the largest bindable uniform array.

RESOLUTION: RESOLVED.

9. *It is not allowed to bind a buffer object to more than one bindable uniform in a program object. There are several operations that could be affected by this rule: UseProgram(), the uniform loading commands Uniform*, Begin, RasterPos and any related rendering command. Should each operation generate an error if the rule is violated?*

DISCUSSION: See also issue 7. The UseProgram command could generate an error if the rule is violated. However, it is possible to change the binding of a buffer object to a bindable uniform even after UseProgram has been issued. Thus should the Uniform* commands also check for this? If so, is that going to be a performance burden on uniform loading? Or should it be undefined? Finally, at rendering time violation of this rule will have to be checked. If violated, it seems to make sense to generate an error.

RESOLUTION: RESOLVED. Make violation of the rule a Begin error and a Uniform* error.

10. *How to provide the ability to use bindable uniform arrays (or bindable uniform arrays of structures) where the amount of data can differ based on the buffer object bound to it?*

DISCUSSION: In other words, the size of the bindable uniform is no longer declared in the shader, but determined by the buffer object backing it. This can be achieved through a variety of ways:

```
bindable uniform vec3 foo[1];
```

Where we would allow indexing 'off the end' of the array 'foo', because

    it is backed by a buffer object. The actual size of the array will be
    implicitly inferred from the buffer object bound to it. It'll be the
    shader's responsibility to not index outside the size of the buffer
    object. That in turn means that the layout in buffer object memory of a
    bindable uniform needs to be exposed to the application.

    Or we could support something like:

```
    bindable uniform vec3 foo[100000]; // Some really big number
```

    and make all accesses inside the buffer object bound to "foo" legal.

    Or we could support something like:

```
    bindable uniform float foo[];

    foo[3] = 1.0;
    foo[i]  = .
```

    Where 'i' could be a run-time index.

    RESOLUTION: For now, we will not support this functionality.

11. *Do we want to have bindable namespaces instead of the uniform qualifier "bindable"?*

    DISCUSSION: Something like this:

```
    bindable {
      vec3 blarg;
      int booyah;
    };
```

    where "blarg" and "booyah" can be referred to directly, but are both
    bindable to the same buffer. You can achieve this with bindable uniforms
    stored in structures:

```
    bindable uniform struct {
      vec3 blarg;
      int booyah;
    } foo;
```

    but then have to use "foo.blarg" and "foo.booyah".

    RESOLUTION: Not in this extension. This might be nice programming sugar,
    but not essential. Such a feature may be added in a future extension
    building on this one.

12. *How can an application load data into a bindable uniform?*

    RESOLUTION: See also issue 2. Uniform variables declared as bindable can
    be loaded using the existing Uniform* commands, or data can be loaded in
    the buffer object bound to the uniform using any of the existing
    mechanisms.

13. *Should it be allowed to load data, using the Uniform* commands, into a buffer object that is bound to more than one bindable uniform variable in a program object?*

    DISCUSSION: It is a Begin error to attempt to render in this situation.

    RESOLUTION: Yes, to be consistent with the Begin error, it is also an error to load a value in this case.

14. *Should a buffer object binding point be provided for bindable uniforms?*

    DISCUSSION: All current OpenGL buffer object manipulation functions take a <target> to which a buffer object must be bound. In this extension, buffer objects are bound to uniforms stored in a program, and are not bound directly to the context. So these bindings may not be used to manipulate the

    RESOLUTION: Yes, a new <target> called UNIFORM_BUFFER_EXT is provided.

    The following is a simple example of creating, binding, and populating a buffer object for a bindable uniform named "stuff", which is an array of vec4 values:

```
   GLuint program, buffer;
   GLint location, size;
   GLfloat values;

    // ... compile shaders and link <program>
    location = glGetUniformLocation(program, "stuff");
    size = GetUniformBufferSize(program, location);
    glGenBuffers(1, &buffer);
    glBindBuffer(GL_UNIFORM_BUFFER_EXT, buffer);
    glBufferData(GL_UNIFORM_BUFFER_EXT, size, NULL, STATIC_READ);
    glUniformBufferEXT(program, location, buffer);
    ...
    glUseProgram(program);
    glUniform4fv(location, count, values);
```

Dependencies

    None

Overview

    Blending capability is extended by defining a constant color that can
    be included in blending equations. A typical usage is blending two
    RGB images. Without the constant blend factor, one image must have
    an alpha channel with each pixel set to the desired blend factor.

New Procedures and Functions

```
    void BlendColorEXT(clampf red,
                       clampf green,
                       clampf blue,
                       clampf alpha);
```

New Tokens

    Accepted by the <sfactor> and <dfactor> parameters of BlendFunc:

```
        CONSTANT_COLOR_EXT                  0x8001
        ONE_MINUS_CONSTANT_COLOR_EXT        0x8002
        CONSTANT_ALPHA_EXT                  0x8003
        ONE_MINUS_CONSTANT_ALPHA_EXT        0x8004
```

    Accepted by the <pname> parameter of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

```
        BLEND_COLOR_EXT                     0x8005
```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the GL Specification (Rasterization)

    None

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

The commands that control blending are now BlendFunc and BlendColorEXT. A constant color to be used in the blending equation is specified by BlendColorEXT. The four parameters are clamped to the range [0,1] before being stored. The default value for the constant blending color is (0,0,0,0).

The constant color can be used in both the source and destination blending factors. Four lines are added to table 4.1 and table 4.2:

Value	Blend Factors	
ZERO	(0, 0, 0, 0)	
ONE	(1, 1, 1, 1)	
DST_COLOR	(Rd/Kr, Gd/Kg, Bd/Kb, Ad/Ka)	
ONE_MINUS_DST_COLOR	(1, 1, 1, 1) - (Rd/Kr,Gd/Kg,Bd/Kb,Ad/Ka)	
SRC_ALPHA	(As, As, As, As) / Ka	
ONE_MINUS_SRC_ALPHA	(1, 1, 1, 1) - (As, As, As, As) / Ka	
DST_ALPHA	(Ad, Ad, Ad, Ad) / Ka	
ONE_MINUS_DST_ALPHA	(1, 1, 1, 1) - (Ad, Ad, Ad, Ad) / Ka	
CONSTANT_COLOR_EXT	(Rc, Gc, Bc, Ac)	NEW
ONE_MINUS_CONSTANT_COLOR_EXT	(1, 1, 1, 1) - (Rc, Gc, Bc, Ac)	NEW
CONSTANT_ALPHA_EXT	(Ac, Ac, Ac, Ac)	NEW
ONE_MINUS_CONSTANT_ALPHA_EXT	(1, 1, 1, 1) - (Ac, Ac, Ac, Ac)	NEW
SRC_ALPHA_SATURATE	(f, f, f, 1)	

Table 4.1: Values controlling the source blending function and the source blending values they compute. Ka = 2**m - 1, where m is the number of bits in the A color component. Kr, Kg, and Kb are similarly determined by the number of bits in the R, G, and B color components. f = min(As, 1-Ad) / Ka.

Value	Blend Factors	
ZERO	(0, 0, 0, 0)	
ONE	(1, 1, 1, 1)	
SRC_COLOR	(Rs/Kr, Gs/Kg, Bs/Kb, As/Ka)	
ONE_MINUS_SRC_COLOR	(1, 1, 1, 1) - (Rs/Kr,Gs/Kg,Bs/Kb,As/Ka)	
SRC_ALPHA	(As, As, As, As) / Ka	
ONE_MINUS_SRC_ALPHA	(1, 1, 1, 1) - (As, As, As, As) / Ka	
DST_ALPHA	(Ad, Ad, Ad, Ad) / Ka	
ONE_MINUS_DST_ALPHA	(1, 1, 1, 1) - (Ad, Ad, Ad, Ad) / Ka	
CONSTANT_COLOR_EXT	(Rc, Gc, Bc, Ac)	NEW
ONE_MINUS_CONSTANT_COLOR_EXT	(1, 1, 1, 1) - (Rc, Gc, Bc, Ac)	NEW
CONSTANT_ALPHA_EXT	(Ac, Ac, Ac, Ac)	NEW
ONE_MINUS_CONSTANT_ALPHA_EXT	(1, 1, 1, 1) - (Ac, Ac, Ac, Ac)	NEW

Table 4.2: Values controlling the destination blending function and the destination blending values they compute. Ka = 2**m - 1, where m is the number of bits in the A color component. Kr, Kg, and Kb are similarly determined by the number of bits in the R, G, and B color components.

Rc, Gc, Bc, and Ac are the four components of the constant blending color. These blend factors are not scaled by Kr, Kg, Kb, and Ka, because they are already in the range [0,1].

Notice

Version

    Date: 12/23/2003 Version 1.0

Status

Shipping as of May 2004 for GeForce6.

Number

299

Dependencies

Written based on the wording of the OpenGL 1.5 specification.

OpenGL 1.4 (or ARB_imaging, or EXT_blend_minmax and/or EXT_blend_subtract) is required for blend equation support.

EXT_blend_func_separate is presumed but not required.

EXT_blend_logic_op interacts with this extension.

Overview

EXT_blend_func_separate introduced separate RGB and alpha blend factors. EXT_blend_minmax introduced a distinct blend equation for combining source and destination blend terms. (EXT_blend_subtract & EXT_blend_logic_op added other blend equation modes.) OpenGL 1.4 integrated both functionalities into the core standard.

While there are separate blend functions for the RGB and alpha blend factors, OpenGL 1.4 provides a single blend equation that applies to both RGB and alpha portions of blending.

This extension provides a separate blend equation for RGB and alpha to match the generality available for blend factors.

IP Status

No known IP issues.

Issues

Why not use ATI_blend_equation_separate?

Apple supports this extension in OS X 10.2 but the extension lacks a specification and, as explained in subsequent issues, the token naming is inconsistent with OpenGL conventions.

What should the token names be?

RESOLVED: Follow the precedent of EXT_blend_equation_separate. For example, GL_BLEND_DST becomes GL_BLEND_DST_RGB and GL_BLEND_DST_ALPHA. So GL_BLEND_EQUATION becomes GL_BLEND_EQUATION_RGB (same value as GL_BLEND_EQUATION) and GL_BLEND_EQUATION_ALPHA.

This is different from the ATI_blend_equation_separate approach which introduces the single name GL_ALPHA_BLEND_EQUATION_ATI (no RGB name is introduced). The existing OpenGL convention (example: ARB_texture_env_combine) is to use _RGB and _ALPHA as a suffix for enumerants, not a prefix.

How should get token values be assigned?

RESOLVED: GL_BLEND_EQUATION_RGB_EXT has the same value as GL_BLEND_EQUATION. See "Compatibility" section.

For compatibility with ATI_blend_equation_separate, GL_BLEND_EQUATION_ALPHA_EXT shares the same value (0x883D) with the ATI_blend_equation_separate's GL_ALPHA_BLEND_EQUATION_ATI token. The GL_BLEND_EQUATION_ALPHA_EXT name uses the suffixing convention (rather than prefixing) for adding _ALPHA addition as done by ARB_texture_env_combine and EXT_blend_func_separate.

New Procedures and Functions

```
void BlendEquationSeparateEXT(enum modeRGB,
                              enum modeAlpha);
```

New Tokens

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
    BLEND_EQUATION_RGB_EXT             0x8009 (same as BLEND_EQUATION)
    BLEND_EQUATION_ALPHA_EXT           0x883D
```

Additions to Chapter 2 of the 1.5 GL Specification (OpenGL Operation)

None

Additions to Chapter 3 of the 1.5 GL Specification (Rasterization)

None

Additions to Chapter 4 of the 1.5 GL Specification (Per-Fragment Operations and the Framebuffer)

Replace the "Blend Equation" discussion in section 4.1.7 (Blending) with the following:

"The equations used to control blending are determined by the blend equations. Blend equations are specified with the commands:

```
  void BlendEquation(enum mode);
  void BlendEquationSeparateEXT(enum modeRGB, enum modeAlpha);
```

BlendEquationSeparateEXT arguments modeRGB determines the RGB blend function while modeAlpha determines the alpha blend equation. BlendEquation argument mode determines both the RGB and alpha blend equations. modeRGB and modeAlpha must each be one of FUNC_ADD, FUNC_SUBTRACT, FUNC_REVERSE_SUBTRACT, MIN, or MAX.

Destination (framebuffer) components are taken to be fixed-point values represented according to the scheme in section 2.13.9 (Final Color Processing), as are source (fragment) components. Constant color components are taken to be floating point values. [ed: paragraph unchanged except that floating-point is hyphenated.]

Prior to blending, each fixed-point color component undergoes an implied conversion to floating-point. This conversion must leave the values 0 and 1 invariant. Blending components are treated as if carried out in floating-point. [ed: paragraph unchanged except that floating-point is hyphenated.]

Table 4.blendeq provides the corresponding per-component blend equations for each mode, whether acting on RGB components for modeRGB or the alpha component for modeAlpha.

In the table, the "s" subscript on a color component abbreviation (R, G, B, or A) refers to the source color component for an incoming fragment, the "d" subscript on a color component abbreviation refers to the destination color component at the corresponding framebuffer location, and the "c" subscript on a color component abbreviation refers to the constant blend color component. A color component abbreviation without a subscript refers to the new color component resulting from blending. Additionally, Sr, Sg, Sb, and Sa are the red, green, blue, and alpha components of the source weighting factors determined by the source blend function, and Dr, Dg, Db, and Da are the red, green, blue, and alpha components of the destination weighting factors determined by the destination blend function. Blend functions are described below.

```
    Mode                    RGB components          Alpha component
    ---------------------   ---------------------   ---------------------
    FUNC_ADD                Rc = Rs * Sr + Rd * Dr  Ac = As * Sa + Ad * Da
                            Gc = Gs * Sg + Gd * Dg
                            Bc = Bs * Sb + Bd * Db
    ---------------------   ---------------------   ---------------------
    FUNC_SUBTRACT           Rc = Rs * Sr - Rd * Dr  Ac = As * Sa - Ad * Da
                            Gc = Gs * Sg - Gd * Dg
                            Bc = Bs * Sb - Bd * Db
    ---------------------   ---------------------   ---------------------
    FUNC_REVERSE_SUBTRACT   Rc = Rd * Sr - Rs * Dr  Ac = Ad * Sa - As * Da
                            Gc = Gd * Sg - Gs * Dg
                            Bc = Bd * Sb - Bs * Db
    ---------------------   ---------------------   ---------------------
    MIN                     Rc = min(Rs, Rd)        Ac = min(As, Ad)
                            Gc = min(Gs, Gd)
                            Bc = min(Bs, Bd)
    ---------------------   ---------------------   ---------------------
    MAX                     Rc = max(Rs, Rd)        Ac = max(As, Ad)
                            Gc = max(Gs, Gd)
                            Bc = max(Bs, Bd)
    ---------------------   ---------------------   ---------------------

    Table 4.blendeq:  RGB and alpha blend equations are their
    per-component equations controlling the color components resulting
    from blending for each mode."

    In the "Blending State" paragraph, replace the initial lines with...

    "The state required for blending is two integers for the RGB and alpha
    blend equations, four integer indicating the source and destination
    RGB and alpha blending functions, four floating-point values to store
    the RGBA constant blend color, and a bit indicating whether blending
    is enabled or disabled.  The initial blending equations for RGB and
    alpha are FUNC_ADD. ..."
```

Additions to Chapter 5 of the 1.5 GL Specification (Special Functions)

    None

Additions to Chapter 6 of the 1.5 GL Specification (State and State Requests)

    None

Additions to the GLX Specification

    None

GLX Protocol

    A new GL rendering command is added. The following command is sent
    to the server as part of a glXRender request:

```
        BlendEquationSeparateEXT
            2           12              rendering command length
            2           4228            rendering command opcode
            4           ENUM            modeRGB
            4           ENUM            modeAlpha
```

Dependencies on EXT_blend_logic_op

    If EXT_blend_logic_op and EXT_blend_equation_separate are both
    supported, the logic op blend equation should be supported separately
    for RGB and alpha as with the other blend equation modes.

    And add to the table 4.blendeq this line:

```
    Mode                    RGB components          Alpha component
    ---------------------   ---------------------   ---------------------
    LOGIC_OP                Rc = Rs OP Rd           Ac = As OP Ad
                            Gc = Gs OP Gd
                            Bc = Bs OP Bd
    ---------------------   ---------------------   ---------------------
```

    where OP denotes the logical operation controlled by LogicOp (see
    table 4.2).

    Note: there is no support for a distinct RGB logical operation
    and alpha logical operation (that could be provided by another
    extension).

Errors

    INVALID_ENUM is generated if either the modeRGB or modeAlpha
    parameter of BlendEquationSeparateEXT is not one of FUNC_ADD,
    FUNC_SUBTRACT, FUNC_REVERSE_SUBTRACT, MAX, or MIN.

    INVALID_OPERATION is generated if BlendEquationSeparateEXT
    is executed between the execution of Begin and the corresponding
    execution of End.

New State

```
                                                  Initial
    Get Value                 Get Command  Type  Value     Attribute
    ------------------------  -----------  ----  --------  ------------
    BLEND_EQUATION_RGB_EXT    GetIntegerv  Z     FUNC_ADD  color-buffer
    BLEND_EQUATION_ALPHA_EXT  GetIntegerv  Z     FUNC_ADD  color-buffer
```

    [remove BLEND_EQUATION from the table, add a note "v1.5 BLEND_EQUATON"
    beside BLEND_EQUATION_RGB_EXT to note the legacy name.]

New Implementation Dependent State

    None

Compatibility

The BLEND_EQUATION_RGB_EXT query token has the same value as the legacy BLEND_EQUATION query token. This means querying the legacy BLEND_EQUATION state is identical to querying the RGB blend equation state.

This is a different approach than taken by the EXT_blend_func_separate extension, but matches the approach taken by other "split" OpenGL state such as the SMOOTH_POINT_SIZE_RANGE and ALIASED_POINT_SIZE_RANGE values split from POINT_SIZE_RANGE.

In the EXT_blend_func_separate case, four new token names (BLEND_DST_RGB, BLEND_SRC_RGB, BLEND_DST_ALPHA, and BLEND_DST_RGB) with four new token values (0x80C8, 0x80C9, 0x80CA, and 0x80CB respectively) were added. Querying the legacy BLEND_DST (0x0BE0) and BLEND_RGB (0x0BE1) returns the same value as querying BLEND_SRC_RGB and BLEND_DST_RGB respectively but this was never explicitly documented.

In the case of the point size ranges, SMOOTH_POINT_SIZE_RANGE was given the same value as POINT_SIZE_RANGE (0x0B12) and a single new token ALIASED_POINT_SIZE_RANGE (0x846D).

The point size ranges approach is preferable because it minimizes the confusion about how the legacy name should be treated by implementations because the legacy name shares its value with the new name. This is less prone to confusion by developers and implementers and less effort to implement.

For token value compatibility with ATI_blend_equation_separate, GL_BLEND_EQUATION_ALPHA_EXT shares the same value (0x883D) with the ATI_blend_equation_separate's GL_ALPHA_BLEND_EQUATION_ATI token.

Dependencies

    None

Overview

    Blending capability is extended by defining a function that allows
    independent setting of the RGB and alpha blend factors for blend
    operations that require source and destination blend factors. It
    is not always desired that the blending used for RGB is also applied
    to alpha.

New Procedures and Functions

```
    void BlendFuncSeparateEXT(enum sfactorRGB,
                              enum dfactorRGB,
                              enum sfactorAlpha,
                              enum dfactorAlpha);
```

New Tokens

    Accepted by the <pname> parameter of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

```
        BLEND_DST_RGB_EXT                 0x80C8
        BLEND_SRC_RGB_EXT                 0x80C9
        BLEND_DST_ALPHA_EXT               0x80CA
        BLEND_SRC_ALPHA_EXT               0x80CB
```

Additions to Chapter 2 of the 1.2 GL Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the 1.2 GL Specification (Rasterization)

    None

Additions to Chapter 4 of the 1.2 GL Specification (Per-Fragment Operations and the Framebuffer)

The RGB and alpha blend factors are separate. The function BlendFuncSeparateEXT allows the specification of the four factors. Table 4.1 and Table 4.2 are modified as follows:

Value	RGB Factors	Alpha Factors
ZERO	(0, 0, 0)	0
ONE	(1, 1, 1)	1
DST_COLOR	(Rd/Kr, Gd/Kg, Bd/Kb)	Ad/Ka
ONE_MINUS_DST_COLOR	(1-Rd/Kr, 1-Gd/Kg, 1-Bd/Kb)	1-Ad/Ka
SRC_ALPHA	(As/Ka, As/Ka, As/Ka)	As/Ka
ONE_MINUS_SRC_ALPHA	(1-As/Ka, 1-As/Ka, 1-As/Ka)	1-As/Ka
DST_ALPHA	(Ad/Ka, Ad/Ka, Ad/Ka)	Ad/Ka
ONE_MINUS_DST_ALPHA	(1-Ad/Ka, 1-Ad/Ka, 1-Ad/Ka)	1-Ad/Ka
CONSTANT_COLOR	(Rc, Gc, Bc)	Ac
ONE_MINUS_CONSTANT_COLOR	(1-Rc, 1-Gc, 1-Bc)	1-Ac
CONSTANT_ALPHA	(Ac, Ac, Ac)	Ac
ONE_MINUS_CONSTANT_ALPHA	(1-Ac, 1-Ac, 1-Ac)	1-Ac
SRC_ALPHA_SATURATE	(f, f, f)	1

Value	RGB Factors	Alpha Factors
ZERO	(0, 0, 0)	0
ONE	(1, 1, 1)	1
SRC_COLOR	(Rs/Kr, Gs/Kg, Bs/Kb)	As/Ka
ONE_MINUS_SRC_COLOR	(1-Rs/Kr, 1-Gs/Kg, 1-Bs/Kb)	1-As/Ka
SRC_ALPHA	(As/Ka, As/Ka, As/Ka)	As/Ka
ONE_MINUS_SRC_ALPHA	(1-As/Ka, 1-As/Ka, 1-As/Ka)	1-As/Ka
DST_ALPHA	(Ad/Ka, Ad/Ka, Ad/Ka)	Ad/Ka
ONE_MINUS_DST_ALPHA	(1-Ad/Ka, 1-Ad/Ka, 1-Ad/Ka)	1-Ad/Ka
CONSTANT_COLOR	(Rc, Gc, Bc)	Ac
ONE_MINUS_CONSTANT_COLOR	(1-Rc, 1-Gc, 1-Bc)	1-Ac
CONSTANT_ALPHA	(Ac, Ac, Ac)	Ac
ONE_MINUS_CONSTANT_ALPHA	(1-Ac, 1-Ac, 1-Ac)	1-Ac
SRC_ALPHA_SATURATE	(f, f, f)	1

The commands that control blending are

```
void BlendFunc(enum src, enum dst)
void BlendFuncSeparateEXT(enum sfactorRGB, enum dfactorRGB,
                          enum sfactorAlpha, enum dfactorAlpha);
```

The BlendFunc command sets both source factors (RGB and alpha) and destination factors (RGB and alpha) while BlendFuncSeparateEXT sets the RGB factors independently from the alpha factors.

Additions to Chapter 5 of the 1.2 GL Specification (Special Functions)

None

Additions to Chapter 6 of the 1.2 GL Specification (State and State Requests)

The state required is four integers indicating the source and destination blending functions for RGB and alpha. The initial state

    for both source functions is ONE. The initial state for both
    destination functions is ZERO.

Additions to the GLX Specification

    None

GLX Protocol

    A new GL rendering command is added. The following command is sent
    to the server as part of a glXRender request:

```
        BlendFuncSeparateEXT
            2           20              rendering command length
            2           4134            rendering command opcode
            4           ENUM            sfactorRGB
            4           ENUM            dfactorRGB
            4           ENUM            sfactorAlpha
            4           ENUM            dfactorAlpha
```

Errors

    GL_INVALID_ENUM is generated if either sfactorRGB, dfactorRGB,
    sfactorAlpha, or dfactorAlpha is not an accepted value.

    GL_INVALID_OPERATION is generated if glBlendFunc is executed between
    the execution of glBegin and the corresponding execution of glEnd.

New State

    The get values BLEND_SRC and BLEND_DST return the RGB source and
    destination factor, respectively.

```

Overview

    Blending capability is extended by respecifying the entire blend
    equation. While this document defines only two new equations, the
    BlendEquationEXT procedure that it defines will be used by subsequent
    extensions to define additional blending equations.

    The two new equations defined by this extension produce the minimum
    (or maximum) color components of the source and destination colors.
    Taking the maximum is useful for applications such as maximum projection
    in medical imaging.

Issues

    *   I've prefixed the ADD token with FUNC, to indicate that the blend
        equation includes the parameters specified by BlendFunc. (The min
        and max equations don't.) Is this necessary? Is it too ugly?
        Is there a better way to accomplish the same thing?

New Procedures and Functions

    void BlendEquationEXT(enum mode);

New Tokens

    Accepted by the <mode> parameter of BlendEquationEXT:

        FUNC_ADD_EXT   0x8006
        MIN_EXT   0x8007
        MAX_EXT   0x8008

    Accepted by the <pname> parameter of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

        BLEND_EQUATION_EXT   0x8009

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

None

Additions to Chapter 3 of the GL Specification (Rasterization)

None

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

The GL Specification defines a single blending equation. This extension introduces a blend equation mode that is specified by calling BlendEquationEXT with one of three enumerated values. The default value FUNC_ADD_EXT specifies that the blending equation defined in the GL Specification be used. This equation is

```
    C' = (Cs * S) + (Cd * D)

         /  1.0     C' > 1.0
    C = (
         \   C'     C' <= 1.0
```

where Cs and Cd are the source and destination colors, and S and D are as specified by BlendFunc.

If BlendEquationEXT is called with <mode> set to MIN_EXT, the blending equation becomes

```
    C = min (Cs, Cd)
```

Finally, if BlendEquationEXT is called with <mode> set to MAX_EXT, the blending equation becomes

```
    C = max (Cs, Cd)
```

In all cases the blending equation is evaluated separately for each color component.

Name

    EXT_clip_volume_hint

Name Strings

    GL_EXT_clip_volume_hint

Version

    Microsoft revision 1.00, April 17, 1996 (hockl)

Number

    79

Dependencies

    None.

Overview

    EXT_clip_volume_hint provides a mechanism for applications to
    indicate that they do not require clip volume clipping for
    primitives. It allows applications to maximize performance in
    situations where they know that clipping is unnecessary.
    EXT_clip_volume_hint is only an indication, though, and
    implementations are free to ignore it.

New Procedures and Functions

    None.

New Tokens

```
    Accepted by the target parameter of Hint and the pname parameter of
    GetBooleanv, GetDoublev, GetFloatv and GetIntegerv:
        CLIP_VOLUME_CLIPPING_HINT_EXT   0x80F0
```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

    Before the last paragraph of Section 2.11, 'Clipping,' the following
    text is added:

        The EXT_clip_volume_hint extension can be used to indicate that
        a primitive falls inside the current clip volume. In this case,
        an implementation might not clip the primitive to the clip
        volume, and the behavior of the GL is undefined if the primitive
        extends beyond the clip volume.

    In the fourth (clipping) paragraph of Section 2.12, 'Current Raster
    Position,' the following text is added before the last sentence
    "Figure 2.7 summarizes..."

        Raster position clipping is not affected by the
        CLIP_VOLUME_CLIPPING_HINT_EXT hint in the EXT_clip_volume_hint
        extension.

Additions to Chapter 3 of the GL Specification (Rasterization)

None.

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

None.

Additions to Chapter 5 of the GL Specification (Special Functions)

Section 5.6, 'Hints,' should be changed to add the following hint description:

CLIP_VOLUME_CLIPPING_HINT_EXT, indicating whether clipping to the clip volume is necessary.

Additions to Chapter 6 of the GL Specification (State and State Requests)

In table 6.18, 'Hints,' the following entry is added:

```
    CLIP_VOLUME_CLIPPING_HINT_EXT|Z3|GetIntegerv|DONT_CARE|
    Clip volume clipping hint|5.6|hint
```

    GL_EXT_compiled_vertex_array

Version

    $Date: 1996/11/21 00:52:19 $ $Revision: 1.3 $

Number

    97

Dependencies

    None

Overview

This extension defines an interface which allows static vertex array data to be cached or pre-compiled for more efficient rendering. This is useful for implementations which can cache the transformed results of array data for reuse by several DrawArrays, ArrayElement, or DrawElements commands. It is also useful for implementations which can transfer array data to fast memory for more efficient processing.

For example, rendering an M by N mesh of quadrilaterals can be accomplished by setting up vertex arrays containing all of the vertexes in the mesh and issuing M DrawElements commands each of which operate on 2 * N vertexes. Each DrawElements command after the first will share N vertexes with the preceding DrawElements command. If the vertex array data is locked while the DrawElements commands are executed, then OpenGL may be able to transform each of these shared vertexes just once.

Issues

* Is compiled_vertex_array the right name for this extension?

* Should there be an implementation defined maximum number of array elements which can be locked at a time (i.e. MAX_LOCKED_ARRAY_SIZE)?

  Probably not, the lock request can always be ignored with no resulting change in functionality if there are insufficent resources, and allowing the GL to define this limit can make things difficult for applications.

* Should there be any restrictions on what state can be changed while the vertex array data is locked?

  Probably not. The GL can check for state changes and invalidate any cached vertex state that may be affected. This is likely to cause a performance hit, so the preferred use will be to not change state while the vertex array data is locked.

New Procedures and Functions

```
    void LockArraysEXT (int first, sizei count)
    void UnlockArraysEXT (void)
```

New Tokens

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
        ARRAY_ELEMENT_LOCK_FIRST_EXT        0x81A8
        ARRAY_ELEMENT_LOCK_COUNT_EXT        0x81A9
```

Additions to Chapter 2 of the 1.1 Specification (OpenGL Operation)

After the discussion of InterleavedArrays, add a description of array compiling/locking.

The currently enabled vertex arrays can be locked with the command LockArraysEXT. When the vertex arrays are locked, the GL can compile the array data or the transformed results of array data associated with the currently enabled vertex arrays. The vertex arrays are unlocked by the command UnlockArraysEXT.

Between LockArraysEXT and UnlockArraysEXT the application should ensure that none of the array data in the range of elements specified by <first> and <count> are changed. Changes to the array data between the execution of LockArraysEXT and UnlockArraysEXT commands may affect calls may affect DrawArrays, ArrayElement, or DrawElements commands in non-sequential ways.

While using a compiled vertex array, references to array elements by the commands DrawArrays, ArrayElement, or DrawElements which are outside of the range specified by <first> and <count> are undefined.

Additions to Chapter 3 of the 1.1 Specification (Rasterization)

None

Additions to Chapter 4 of the 1.1 Specification (Per-Fragment Operations and the Frame Buffer)

Dependencies

    Written based on the wording of the OpenGL 1.3 specification.

Overview

This extension adds a new per-fragment test that is, logically, after the scissor test and before the alpha test. The depth bounds test compares the depth value stored at the location given by the incoming fragment's (xw,yw) coordinates to a user-defined minimum and maximum depth value. If the stored depth value is outside the user-defined range (exclusive), the incoming fragment is discarded.

Unlike the depth test, the depth bounds test has NO dependency on the fragment's window-space depth value.

This functionality is useful in the context of attenuated stenciled shadow volume rendering. To motivate the functionality's utility in this context, we first describe how conventional scissor testing can be used to optimize shadow volume rendering.

If an attenuated light source's illumination can be bounded to a rectangle in XY window-space, the conventional scissor test can be used to discard shadow volume fragments that are guaranteed to be outside the light source's window-space XY rectangle. The stencil increments and decrements that would otherwise be generated by these scissored fragments are inconsequential because the light source's illumination can pre-determined to be fully attenuated outside the scissored region. In other words, the scissor test can be used to discard shadow volume fragments rendered outside the scissor, thereby improving performance, without affecting the ultimate illumination of these pixels with respect to the attenuated light source.

This scissoring optimization can be used both when rendering the stenciled shadow volumes to update stencil (incrementing and decrementing the stencil buffer) AND when adding the illumination contribution of attenuated light source's.

In a similar fashion, we can compute the attenuated light source's window-space Z bounds (zmin,zmax) of consequential illumination. Unless a depth value (in the depth buffer) at a pixel is within the range [zmin,zmax], the light source's illumination can be pre-determined to be inconsequential for the pixel. Said another way, the pixel being illuminated is either far enough in front of or behind the attenuated light source so that the light source's illumination for the pixel is fully attenuated. The depth bounds test can perform this test.

Issues

Where should the depth bounds test take place in the OpenGL fragment processing pipeline?

RESOLUTION: After scissor test, before alpha test. In practice, this is a logical placement of the test. An implementation is free to perform the test in a manner that is consistent with the specified ordering.

Importantly, the depth bounds test occurs before any fragment operation that has a side-effect such as stencil and/or depth buffer writes (ie, the stencil or depth test). This makes it possible to discard incoming fragment's without concern for preserving such side-effects.

Is the depth bounds test consistent with early depth rejection?

Yes. If an OpenGL implementation supports some conservative bounds on depth values in subregions of the depth buffer (hierarchical depth buffers, etc), the depth bounds test can reject fragments based on these conservative bounds.

How are the depth bounds specified?

RESOLUTION: Normalized window-space depth values. This means the depth values are specified in the range [0.0, 1.0] similar to glDepthRange.

Can the zmin bound be greater than the zmax bound?

RESOLUTION: zmin must be less than or equal to zmax or an INVALID_VALUE error is generated.

Another way to interpret this situation is to have zmin>zmax reject all fragments where the corresponding pixel's depth value is between zmin and zmax. But this does not seem useful enough to specify.

What should the glDepthBoundsEXT routine mimic?

RESOLUTION: glDepthBoundsEXT should mimic glDepthRange in parameter types and clamping, excepting that zmin must be less than zmax.

Do the depth bounds have anything to do with the depth range?

RESOLUTION: No. These are totally independent pieces of state. To reinforce the point, having a depth range and depth bounds with no overlap is perfectly well-defined (even if a little odd).

What push/pop attrib bits should affect the depth bounds test enable?

RESOLUTION: GL_ENABLE_BIT and GL_DEPTH_BUFFER_BIT.

How does depth bounds testing interact with polygon offset or depth replace operations (say from ARB_fragment_program, NV_texture_shader, or NV_fragment_program)?

RESOLUTION: There are NO interactions. The depth bounds test has NO dependency on the incoming fragment's depth value so it doesn't matter if there is a polygon offset or depth replace operation.

Does depth bounds testing affect bitmap/draw/copy pixels operations involving depth component pixels?

RESOLUTION: Yes, depth bounds testing affects all rasterized primitives (just like all other fragment operations).

How does depth bounds test interact with multisampling?

RESOLUTION: The depth bounds test is performed per-sample when multisampling is active, just like the depth test.

At what precision is the depth bounds test carried out?

RESOLUTION: For the purposes of the test, the bounds are converted to fixed-point as though they were to be written to the depth buffer, and the comparison uses those quantized bounds.

Can you have the depth test disabled and still have the depth bounds test enabled?

RESOLUTION: Yes. The two tests operate independently.

How does the depth bounds test operate if there is no depth buffer?

RESOLUTION: It is as if the depth bounds test always passes (analogous to the depth test).

New Procedures and Functions

```
void DepthBoundsEXT(clampd zmin, clampd zmax);
```

New Tokens

    Accepted by the <cap> parameter of Enable, Disable, and IsEnabled,
    and by the <pname> parameter of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

        DEPTH_BOUNDS_TEST_EXT   0x8890

        DEPTH_BOUNDS_EXT   0x8891

Additions to Chapter 2 of the OpenGL 1.3 Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the OpenGL 1.3 Specification (Rasterization)

    None

Additions to Chapter 4 of the OpenGL 1.3 Specification (Per-Fragment Operations and the Framebuffer)

-- Figure 4.1 Per-fragment operations

    Add a block for the "depth bounds test" after the scissor and before
    the alpha test.

-- Section 4.1.X Depth Bounds Test (following Section 4.1.2 Scissor Test)

    "The depth bounds test determines whether the depth value (Zpixel)
    stored at the location given by the incoming fragment's (xw,yw)
    location lies within the depth bounds range defined by two values.
    These values are set with

        void DepthBoundsEXT(clampd zmin, clampd zmax);

    Each of zmin and zmax are clamped to lie within [0,1] (being of
    type clampd). If zmin <= Zpixel <= zmax, then the depth bounds test
    passes. Otherwise, the test fails and the fragment is discarded.
    The test is enabled or disabled using Enable or Disable using the
    constant DEPTH_BOUNDS_TEST_EXT. When disabled, it is as if the depth
    bounds test always passes. If zmin is greater than zmax, then the
    error INVALID_VALUE is generated. The state required consists of
    two floating-point values and a bit indicating whether the test is
    enabled or disabled. In the initial state, zmin and zmax are set
    to 0.0 and 1.0 respectively; and the depth bounds test is disabled.

    If there is no depth buffer, it is as if the depth bounds test always
    passes."

-- Section 4.10 Additional Multisample Fragment Operations

    Add depth bounds test to the list of operations affected by
    multisampling. Amend the 1st and 2nd sentences in the 2nd paragraph
    to read:

    "If MULTISAMPLE is enabled, and the value of SAMPLE_BUFFERS is one,
    the depth bounds test, alpha test, depth test, blending, and dithering
    operations are performed for each pixel sample, rather than just once
    for each fragment. Failure of the depth bounds, alpha, stencil, or
    depth test results in termination of the processing of the sample,
    rather than discarding of the fragment."

    Amend the 1st sentence in the 3nd paragraph to read:

    "Depth bounds, stencil, depth, blending, and dithering operations
    are performed for a pixel sample only if that sample's fragment
    coverage bit is a value of 1."

    Amend the 3rd sentence in the 4th paragraph to read:

    "An implementation may choose to identify a centermost sample, and
    to perform depth bounds, alpha, stencil, and depth tests on only
    that sample."

Dependencies

The extension is written against the OpenGL 2.0 Specification.

OpenGL 2.0 is required.

Overview

This extension builds upon the ARB_draw_buffers extension and provides separate blend enables and color write masks for each color output. In ARB_draw_buffers (part of OpenGL 2.0), separate values can be written to each color buffer, but the blend enable and color write mask are global and apply to all color outputs.

While this extension does provide separate blend enables, it does not provide separate blend functions or blend equations per color output.

New Procedures and Functions

```
    void ColorMaskIndexedEXT(uint buf, boolean r, boolean g,
                             boolean b, boolean a);

    void GetBooleanIndexedvEXT(enum value, uint index, boolean *data);

    void GetIntegerIndexedvEXT(enum value, uint index, int *data);

    void EnableIndexedEXT(enum target, uint index);

    void DisableIndexedEXT(enum target, uint index);

    boolean IsEnabledIndexedEXT(enum target, uint index);
```

New Tokens

    None.

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

    None.

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

    None.

Additions to Chapter 4 of the OpenGL 2.0 Specification (Per-Fragment Operations and the Frame Buffer)

Modify the thrid paragraph of section 4.1.8 (Blending) , p206, to read as follows:

Blending is dependent on the incoming fragment's alpha value and that of the corresponding currently stored pixel. Blending applies only in RGBA mode; in color index mode it is bypassed. Blending is enabled or disabled for an individual draw buffer using

```
void EnableIndexedEXT(GLenum target, GLuint index);
void DisableIndexedEXT(GLenum target, GLuint index);
```

<target> is the symbolic constant BLEND and <index> is an integer i specifying the draw buffer associated with the symbolic constant DRAW_BUFFERi. If the color buffer associated with DRAW_BUFFERi is one of FRONT, BACK, LEFT, RIGHT, or FRONT_AND_BACK (specifying multiple color buffers), then the state enabled or disabled is applicable for all of the buffers. Blending can be enabled or disabled for all draw buffers using Enable or Disable with the symbolic constant BLEND. If blending is disabled for a particular draw buffer, or if logical operation on color values is enabled (section 4.1.10), proceed to the next operation.

Modify the first paragraph of section 4.1.8 (Blending - Blending State), p209, to read as follows:

The state required for blending is two integers for the RGB and alpha blend equations, four integers indicating the source and destination RGB and alpha blending functions, four floating-point values to store the RGBA constant blend color, and n bits indicating whether blending is enabled or disabled for each of the n draw buffers. The initial blend equations for RGB and alpha are both FUNC_ADD. The initial blending functions are ONE for the source RGB and alpha functions, and ZERO for the destination RGB and alpha functions. The initial constant blend color is (R, G, B, A) = (0, 0, 0, 0). Initially, blending is disabled for all draw buffers.

Modify the first paragraph of section 4.2.2 (Fine Control of Buffer Updates) to read as followS:

Three commands are used to mask the writing of bits to each of the logical draw buffers after all per-fragment operations have been performed.

The commands

```
    void IndexMask(uint mask);
    void ColorMask(boolean r, boolean g, boolean b, boolean a);
    void ColorMaskIndexedEXT(uint buf, boolean r, boolean g,
                             boolean b, boolean a);
```

control writes to the active draw buffers.

The least significant n bits of <mask>, where n is the number of bits in a color index buffer, specify a mask. Where a 1 appears in this mask, the corresponding bit in the color index buffer (or buffers) is written; where a 0 appears, the bit is not written. This mask applies only in color index mode.

In RGBA mode, ColorMask and ColorMaskIndexedEXT are used to mask the writing of R, G, B and A values to the draw buffer or buffers. ColorMaskIndexedEXT sets the mask for a particular draw buffer. The mask for DRAW_BUFFERi is modified by passing i as the parameter <buf>. <r>, <g>, <b>, and <a> indicate whether R, G, B, or A values, respectively, are written or not (a value of TRUE means that the corresponding value is written). The mask specified by <r>, <g>, <b>, and <a> is applied to the color buffer associated with DRAW_BUFFERi. If DRAW_BUFFERi is one of FRONT, BACK, LEFT, RIGHT, or FRONT_AND_BACK (specifying multiple color buffers) then the mask is applied to all of the buffers. ColorMask sets the mask for all draw buffers to the same values as specified by <r>, <g>, <b>, and <a>.

Additions to Chapter 5 of the OpenGL 2.0 Specification (Special Functions)

None.

Additions to Chapter 6 of the OpenGL 2.0 Specification (State and State Requests)

Modify the second paragraph of section 6.1.1 (Simple Queries) p244 to read as follows:

...<data> is a pointer to a scalar or array of the indicated type in which to place the returned data.

```
    void GetBooleanIndexedvEXT(enum target, uint index, boolean *data);
    void GetIntegerIndexedvEXT(enum target, uint index, int *data);
```

are used to query indexed state. <target> is the name of the indexed state and <index> is the index of the particular element being queried. <data> is a pointer to a scalar or array

```
    of the indicated type in which to place the returned data.  In
    addition

        boolean IsEnabled(enum value);

    can be used to determine if <value> is currently enabled (as with
    Enable) or disabled.

        boolean IsEnabledIndexedEXT(enum target, uint index);

    can be used to determine if the index state corresponding to
    <target> and <index> is enabled or disabled.
```

Additions to Appendix A of the OpenGL 2.0 Specification (Invariance)

None.

Additions to the AGL/GLX/WGL Specifications

None.

Errors

The error INVALID_ENUM is generated by EnableIndexedEXT and DisableIndexedEXT if the <target> parameter is not BLEND.

The error INVALID_OPERATION is generated by EnableIndexedEXT and DisableIndexeEXT if the <target> parameter is BLEND and the <index> parameter is outside the range [0, MAX_DRAW_BUFFERS-1].

The error INVALID_ENUM is generated by IsEnabledIndexedEXT if the <target> parameter is not BLEND.

The error INVALID_OPERATION is generated by IsEnabledIndexedEXT if the <target> parameter is BLEND and the <index> parameter is outside the range [0, MAX_DRAW_BUFFERS-1].

The error INVALID_OPERATION is generated by DrawBufferColorMaskEXT if the <buf> parameter is outside the range [0, MAX_DRAW_BUFFERS-1].

The error INVALID_ENUM is generated by GetBooleanIndexedvEXT if the <target> parameter is not BLEND.

The error INVALID_OPERATION is generated by GetBooleanIndexedvEXT if the <target> parameter is BLEND and the <index> parameter is outside the range [0, MAX_DRAW_BUFFERS-1].

New State

    Modify (table 6.20, p281), modifying the entry for BLEND and adding
    a new one.

Get Target	Type	Get Command	Value	Description	Section	Attribute
BLEND	B	IsEnabled	False	Blending enabled for draw buffer 0	4.1.8	color-buffer/enable
BLEND	B	IsEnabledIndexedEXT	False	Blending enabled for draw buffer i where i is specified as <index>	4.1.8	color-buffer/enable

    Modify (table 6.21, p282), modifying the entry for COLOR_WRITEMASK
    and adding a new one.

Get Value	Type	Get Command	Value	Description	Section	Attribute
COLOR_WRITEMASK	4xB	GetBooleanv	True	Color write mask for draw buffer 0	4.2.2	color-buffer
COLOR_WRITEMASK	4xB	GetBooleanIndexedvEXT	True	Color write mask for draw buffer i where i is specified as <index>	4.2.2	color-buffer

Issues

1. Should the extension provide support for per draw buffer index masks as well as per draw buffer color masks?

RESOLVED: No. Color index rendering is not interesting enough to warrant extending the API in this direction.

2. Should the API for specifying separate color write masks be based on DrawBuffers() (specifying an array of write masks at once)?

RESOLVED: No. There are two ways to mimic the DrawBuffers() API. A function, ColorMasks(), could take an an element count and an array of four element boolean arrays as parameters. Each four element boolean array contains a set of red, green, blue, and alpha write masks for a specific color buffer. An alternative is a ColorMasks() function that takes an element count and four parallel boolean arrays with one array per color channel. Neither approach is particularly clean. A cleaner approach, taken by ColorMaskIndexedEXT(), is to specify a color mask for a single draw buffer where the draw buffer is specified as a parameter to the function.

3. How should ColorMask() affect the per color buffer write masks?

RESOLVED: ColorMask() should set all color buffer write masks to the same values. This is backwards compatible with the way ColorMask() behaves in the absence of this extension.

4. What should GetBooleanv return when COLOR_WRITEMASK is queried?

RESOLVED: COLOR_WRITEMASK should return DRAW_BUFFER0_COLOR_WRITEMASK_EXT. This is backwards compatible with the way the query works without this extension. To query the writemask associated with a particular draw buffer, an application can use GetBooleanIndexedvEXT.

5. How are separate blend enables controlled? Should a new function be introduced, or do Enable() and Disable() provide sufficient functionality?

RESOLVED: This extension introduces new functions EnableIndexedEXT and DisableIndexedEXT that can be used to enable/disable individual states of a state array. These functions are introduced because there is a trend towards introducing arrays of state. Rather than creating enums for each index in the array, it is better to give applications a mechanism for accessing a particular element of the state array given the name of the state and an index into the array.

6. What effect does enabling or disabling blending using BLEND have on per draw buffer blend enables?

RESOLVED: BLEND, used with Enable() and Disable(), should enable or disable all per draw buffer blend enables. This is similar to the way that ColorMask() affects the per draw buffer write masks.

Michael Gold, NVIDIA Corporation (gold 'at' nvidia.com)

Status

    Shipping for GeForce 8 Series (November 2006)

Version

    Last Modified Date: November 6, 2006
    Author Revision: 1.4

Number

    327

Dependencies

    OpenGL 2.0 is required.

    EXT_gpu_shader4 or NV_vertex_shader4 is required.

Overview

    This extension provides the means to render multiple instances of
    an object with a single draw call, and an "instance ID" variable
    which can be used by the vertex program to compute per-instance
    values, typically an object's transform.

New Tokens

    None

New Procedures and Functions

```
void DrawArraysInstancedEXT(enum mode, int first, sizei count,
        sizei primcount);
void DrawElementsInstancedEXT(enum mode, sizei count, enum type,
        const void *indices, sizei primcount);
```

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

Modify section 2.8 (Vertex Arrays), p. 23

(insert before the final paragraph, p. 30)

The internal counter <instanceID> is a 32-bit integer value which may be read by a vertex program as <vertex.instance>, as described in section 2.X.3.2, or vertex shader as <gl_InstanceID>, as described in section 2.15.4.2. The value of this counter is always zero, except as noted below.

The command

```
    void DrawArraysInstancedEXT(enum mode, int first, sizei count,
            sizei primcount);
```

behaves identically to DrawArrays except that <primcount> instances of the range of elements are executed and the value of <instanceID> advances for each iteration. It has the same effect as:

```
    if (mode or count is invalid)
        generate appropriate error
    else {
        for (i = 0; i < primcount; i++) {
            instanceID = i;
            DrawArrays(mode, first, count, i);
        }
        instanceID = 0;
    }
```

The command

```
    void DrawElementsInstancedEXT(enum mode, sizei count, enum type,
            const void *indices, sizei primcount);
```

behaves identically to DrawElements except that <primcount> instances of the set of elements are executed, and the value of <instanceID> advances for each iteration. It has the same effect as:

```
    if (mode, count, or type is invalid )
        generate appropriate error
    else {
        for (int i = 0; i < primcount; i++) {
            instanceID = i;
            DrawElements(mode, count, type, indices, i);
        }
        instanceID = 0;
    }
```

Additions to Chapter 5 of the OpenGL 2.0 Specification (Special Functions)

The error INVALID_OPERATION is generated if DrawArraysInstancedEXT or DrawElementsInstancedEXT is called during display list compilation.

Dependencies on NV_vertex_program4

If NV_vertex_program4 is not supported, all references to vertex.instance are deleted.

Dependencies on EXT_gpu_shader4

If EXT_gpu_shader4 is not supported, all references to gl_InstanceID are deleted.

Errors

INVALID_ENUM is generated by DrawElementsInstancedEXT if <type> is not one of UNSIGNED_BYTE, UNSIGNED_SHORT or UNSIGNED_INT.

INVALID_VALUE is generated by DrawArraysInstancedEXT if <first> is less than zero.

Issues

(1) Should instanceID be provided by this extension, or should it be provided by EXT_gpu_shader4, thus creating a dependence on that spec?

Resolved: While this extension could stand alone, its utility would be limited without the additional functionality provided by EXT_gpu_shader4; also, the spec language is cleaner if EXT_gpu_shader4 assumes instanceID is always available, even if its value is always zero without this extension.

(2) Should MultiDrawArrays and MultiDrawElements affect the value of instanceID?

Resolved: No, this may cause implementation difficulties and is considered unlikely to provide any real benefit.

(3) Should DrawArraysInstanced and DrawElementsInstanced be compiled into display lists?

Resolved: No, calling these during display list compilation generate INVALID_OPERATION.

Version

    $Date: 1997/5/19

Number

    112

Status

    Superceded by OpenGL 1.2 functionaltity.
    See section 2.8 (page 25) of the OpenGL 1.2.1 specification.

Proposal

Add a new vertex array rendering command:

```
void glDrawRangeElementsEXT(
        GLenum mode,
        GLuint start,
        GLuint end,
        GLsizei count,
        GLenum type,
        const GLvoid *indices
);
```

Add two implementation-dependent limits for describing data size recommendations for glDrawRangeElementsEXT:

```
GL_MAX_ELEMENTS_VERTICES_EXT  0x80E8
GL_MAX_ELEMENTS_INDICES_EXT   0x80E9
```

glDrawRangeElementsEXT is a restricted form of glDrawElements. All vertices referenced by indices must lie between start and end inclusive. Not all vertices between start and end must be referenced, however unreferenced vertices may be sent through some of the vertex pipeline before being discarded, reducing performance from what could be achieved by an optimal index set. Index values which lie outside the range will cause implementation-dependent results.

glDrawRangeElementsEXT may also be further constrained to only operate at maximum performance for limited amounts of data. Implementations may advertise recommended maximum amounts of vertex and index data using the GL_MAX_ELEMENTS_VERTICES_EXT and GL_MAX_ELEMENTS_INDICES_EXT enumerants. If a particular call to glDrawRangeElementsEXT has (end-start+1) greater than GL_MAX_ELEMENTS_VERTICES_EXT or if count is greater than GL_MAX_ELEMENTS_INDICES_EXT then the implementation may be forced to process the data less efficiently than it could have with less data. An implementation which has no effective limits can advertise the maximum integer value for the two enumerants. An implementation must always process a glDrawRangeElementsEXT call with valid parameters regardless of the amount of data passed in the call.

GL_INVALID_VALUE will be returned if end is less than start. Other errors are as for glDrawElements.

Motivation:
Rendering primitives from indexed vertex lists is a fairly common graphics operation, particularly in modeling applications such as VRML viewers. OpenGL 1.1 added support for the glDrawElements API to allow rendering of primitives by indexing vertex array data.

The specification of glDrawElements does not allow optimal performance for some OpenGL implementations, however. In particular, it has no restrictions on the number of indices given, the number of unique vertices referenced nor a direct indication of the set of unique vertices referenced by the given indices. This forces some OpenGL implementations to walk the index data given, building up a separate list of unique vertex references for later use in the pipeline. Additionally, since some OpenGL implementations have internal limitations on how many vertices they can deal with simultaneously the unbounded nature of glDrawElements requires the implementation to be prepared to segment the input data and do multiple passes. These preprocessing steps can consume a significant amount of time.

Such preprocessing can be done once and stored when building display lists but this only works for objects whose geometry does not change. Applications using morphing objects or other objects that are changing dynamically cannot take advantage of display lists and so must pay the preprocessing penalty on every redraw.

glDrawRangeElementsEXT is designed to avoid the preprocessing steps which may be necessary for glDrawElements. As such it does not have the flexibility of glDrawElements but it is sufficiently functional for a large class of applications to benefit from its use.
glDrawRangeElementsEXT enhances glDrawElements in two ways:
1. The set of unique vertices referenced by the indices is explicitly indicated via the start and end parameters, removing the necessity to determine this through examination of the index data. The implementation is given a contiguous chunk of vertex data that it can immediately begin streaming through the vertex pipeline.
2. Recommended limits on the amount of data to be processed can be indicated by the implementation through GL_MAX_ELEMENTS_VERTICES_EXT and GL_MAX_ELEMENTS_INDICES_EXT. If an application respects these limits it removes the need to split the incoming data into multiple chunks since the maximums can be set to the optimal values for the implementation to handle in one pass.

The first restriction isn't particularly onerous for applications since they can always call glDrawElements in the case where they cannot or do not know whether they can call glDrawRangeElementsEXT. Performance should be at least as good as it was calling glDrawElements alone. The second point isn't really a restriction as glDrawRangeElementsEXT doesn't fail if the data size limits are exceeded.

OpenGL implementation effort is also minimal. For implementations where glDrawElements performance is not affected by preprocessing glDrawRangeElementsEXT can be implemented simply as a call to glDrawElements and the maximums set to the maximum integer value. For the case where glDrawElements is doing non-trivial preprocessing there is probably already an underlying routine that takes consecutive, nicely sectioned index and vertex chunks that glDrawRangeElementsEXT can plug directly in to.

Design Decisions

The idea of providing a set of vertex indices along with a set of element indices was considered but dropped as it still may require some preprocessing, although there is some reduction in overhead from glDrawElements. The implementation may require internal vertex data to be contiguous, in which case a gather operation would have to be performed with the vertex index list before vertex data could be processed. It is expected that most apps will keep vertex data for particular elements packed consecutively anyway so the added flexibility of a vertex index list would potentially impose overhead with little expected benefit. In the case where a vertex index list really is necessary to avoid performance penalties due to sparse vertex usage glDrawElements should provide performance similar to what such an API would have.

The restriction on maximum data size cannot easily be lifted without potential performance implications. For implementations which have an internal maximum vertex buffer size it would be necessary to break up large data sets into multiple chunks. Splitting indexed data requires walking the indices and gathering those that fall within particular chunks into sets for processing, a time-consuming operation. Splitting the indices themselves is easier but still requires some processing to handle connected primitives that cross a split.

Status

    Complete. Approved by the ARB "superbuffers" working group on
    November 8, 2005.

Version

    Last Modified Date: September 29, 2006
    Author Revision: 14

Number

    316

Dependencies

    OpenGL 1.1 is required.

    EXT_framebuffer_object is required.

    The extension is written against the OpenGL 1.5 specification.

    ARB_color_buffer_float affects the definition of this extension.

Overview

    This extension modifies EXT_framebuffer_object by splitting the
    framebuffer object binding point into separate DRAW and READ
    bindings. This allows copying directly from one framebuffer to
    another. In addition, a new high performance blit function is

    added to facilitate these blits and perform some data conversion
    where allowed.

IP Status

    No known IP claims.

New Procedures and Functions

```
    void BlitFramebufferEXT(int srcX0, int srcY0, int srcX1, int srcY1,
                            int dstX0, int dstY0, int dstX1, int dstY1,
                            bitfield mask, enum filter);
```

New Tokens

    Accepted by the <target> parameter of BindFramebufferEXT,
    CheckFramebufferStatusEXT, FramebufferTexture{1D|2D|3D}EXT,
    FramebufferRenderbufferEXT, and
    GetFramebufferAttachmentParameterivEXT:

```
    READ_FRAMEBUFFER_EXT                0x8CA8
    DRAW_FRAMEBUFFER_EXT                0x8CA9
```

    Accepted by the <pname> parameters of GetIntegerv, GetFloatv, and
    GetDoublev:

```
    DRAW_FRAMEBUFFER_BINDING_EXT        0x8CA6 // alias FRAMEBUFFER_BINDING_EXT
    READ_FRAMEBUFFER_BINDING_EXT        0x8CAA
```

Additions to Chapter 2 of the OpenGL 1.5 Specification (OpenGL Operation)

Append the following to section 2.6.1:

    "Calling Begin will result in an INVALID_FRAMEBUFFER_OPERATION_EXT
    error if the object bound to DRAW_FRAMEBUFFER_BINDING_EXT is not
    "framebuffer complete" (section 4.4.4.2)."

Additions to Chapter 3 of the OpenGL 1.5 Specification (Rasterization)

Add to section 3.6.3, at the end of the subsection titled "Alternate Color Table Specification Commands":

    "Calling CopyColorTable or CopyColorSubTable will result in an
    INVALID_FRAMEBUFFER_OPERATION_EXT error if the object bound to
    READ_FRAMEBUFFER_BINDING_EXT is not "framebuffer complete"
    (section 4.4.4.2)."

Add to section 3.6.3, at the end of the subsection titled "Alternate Convolution Filter Specification Commands":

    "Calling CopyConvolutionFilter1D or CopyConvolutionFilter2D will
    result in an INVALID_FRAMEBUFFER_OPERATION_EXT error if the object
    bound to READ_FRAMEBUFFER_BINDING_EXT is not "framebuffer
    complete" (section 4.4.4.2)."

In section 3.6.4, modify the final paragraph of the definition of DrawPixels as follows:

"Calling DrawPixels will result in an INVALID_FRAMEBUFFER_OPERATION_EXT error if the object bound to DRAW_FRAMEBUFFER_BINDING_EXT is not "framebuffer complete" (section 4.4.4.2)."

Add the following to section 3.7, following the description of Bitmap:

"Calling Bitmap will result in an INVALID_FRAMEBUFFER_OPERATION_EXT error if the object bound to DRAW_FRAMEBUFFER_BINDING_EXT is not "framebuffer complete" (section 4.4.4.2)."

Append the following to section 3.8.2:

"Calling CopyTexImage3D, CopyTexSubImage3D, CopyTexImage2D, CopyTexSubImage2D, CopyTexImage1D or CopyTexSubImage1D will result in an INVALID_FRAMEBUFFER_OPERATION_EXT error if the object bound to READ_FRAMEBUFFER_BINDING_EXT is not "framebuffer complete" (section 4.4.4.2)."

Additions to Chapter 4 of the OpenGL 1.5 Specification (Per-Fragment Operations and the Frame Buffer)

Change the first word of Chapter 4 from "The" to "A".

Append to the introduction of Chapter 4:

"Conceptually, the GL has two active framebuffers; the draw framebuffer is the destination for rendering operations, and the read framebuffer is the source for readback operations. The same framebuffer may be used for both drawing and reading. Section 4.4.1 describes the mechanism for controlling framebuffer usage."

Modify the last paragraph of section 4.1.1 as follows:

"While an application-created framebuffer object is bound to DRAW_FRAMEBUFFER_EXT, the pixel ownership test always passes."

Modify the last sentence of the second to last paragraph of section 4.2.4 as follows:

"If there is no accumulation buffer, or if the DRAW_FRAMEBUFFER_EXT and READ_FRAMEBUFFER_EXT bindings (section 4.4.4.2) do not refer to the same object, or if the GL is in color index mode, Accum generates the error INVALID_OPERATION."

Add to 4.3.2 (Reading Pixels), right before the subsection titled "Obtaining Pixels from the Framebuffer":

"Calling ReadPixels generates INVALID_FRAMEBUFFER_OPERATION_EXT if the object bound to READ_FRAMEBUFFER_BINDING_EXT is not "framebuffer complete" (section 4.4.4.2)."

In section 4.3.2, modify the definition of ReadBuffer as follows:

"The command

```
     void ReadBuffer( enum src );
```

takes a symbolic constant as argument. <src> must be one of the values from tables 4.4 or 10.nnn. Otherwise, INVALID_ENUM is generated. Further, the acceptable values for <src> depend on whether the GL is using the default window-system-provided framebuffer (i.e., READ_FRAMEBUFFER_BINDING_EXT is zero), or an application-created framebuffer object (i.e., READ_FRAMEBUFFER_BINDING_EXT is non-zero). For more information about application-created framebuffer objects, see section 4.4.

When READ_FRAMEBUFFER_BINDING_EXT is zero, i.e. the default window-system-provided framebuffer, <src> must be one of the values listed in table 4.4. FRONT and LEFT refer to the front left buffer, BACK refers to the back left buffer, and RIGHT refers to the front right buffer. The other constants correspond directly to the buffers that they name. If the requested buffer is missing, then the error INVALID_OPERATION is generated. For the default window-system-provided framebuffer, the initial setting for ReadBuffer is FRONT if there is no back buffer and BACK otherwise.

ReadBuffer will set the read buffer for input colors other than 0 to NONE.

Modify the first sentence of section 4.3.3 as follows:

"CopyPixels transfers a rectangle of pixel values from one region of the read framebuffer to another in the draw framebuffer."

Add the following text to section 4.3.3, page 194, inside the definition of CopyPixels:

"Finally, the behavior of several GL operations is specified "as if the arguments were passed to CopyPixels." These operations include: CopyTex{Sub}Image*, CopyColor{Sub}Table, and CopyConvolutionFilter*. INVALID_FRAMEBUFFER_OPERATION_EXT will be generated if an attempt is made to execute one of these operations, or CopyPixels, while the object bound to READ_FRAMEBUFFER_BINDING_EXT is not "framebuffer complete" (as defined in section 4.4.4.2). Furthermore, an attempt to execute CopyPixels will generate INVALID_FRAMEBUFFER_OPERATION_EXT while the object bound to DRAW_FRAMEBUFFER_BINDING_EXT is not "framebuffer complete"."

Append to section 4.3.3:

"BlitFramebufferEXT transfers a rectangle of pixel values from one region of the read framebuffer to another in the draw framebuffer. There are some important distinctions from CopyPixels, as described below.

```
BlitFramebufferEXT(int srcX0, int srcY0, int srcX1, int srcY1,
                   int dstX0, int dstY0, int dstX1, int dstY1,
                   bitfield mask, enum filter);
```

<mask> is the bitwise OR of a number of values indicating which buffers are to be copied. The values are COLOR_BUFFER_BIT, DEPTH_BUFFER_BIT, and STENCIL_BUFFER_BIT, which are described in section 4.2.3. The pixels corresponding to these buffers are copied from the source rectangle, bound by the locations (srcX0, srcY0) and (srcX1, srcY1), to the destination rectangle, bound by the locations (dstX0, dstY0) and (dstX1, dstY1). The lower bounds of the rectangle are inclusive, while the upper bounds are exclusive.

If the source and destination rectangle dimensions do not match, the source image is stretched to fit the destination rectangle. <filter> must be LINEAR or NEAREST and specifies the method of interpolation to be applied if the image is stretched. LINEAR filtering is allowed only for the color buffer; if <mask> includes DEPTH_BUFFER_BIT or STENCIL_BUFFER_BIT, and filter is not NEAREST, no copy is performed and an INVALID_OPERATION error is generated. If the source and destination dimensions are identical, no filtering is applied. If either the source or destination rectangle specifies a negative dimension, the image is reversed in the corresponding direction. If both the source and destination rectangles specify a negative dimension for the same direction, no reversal is performed.

If the source and destination buffers are identical, and the source and destination rectangles overlap, the result of the blit operation is undefined.

The pixel copy bypasses the fragment pipeline. The only fragment operations which affect the blit are the pixel ownership test and the scissor test.

If a buffer is specified in <mask> and does not exist in both the read and draw framebuffers, the corresponding bit is silently ignored.

If the color formats of the read and draw framebuffers do not match, and <mask> includes COLOR_BUFFER_BIT, the pixel groups are converted to match the destination format as in CopyPixels, except that no pixel transfer operations apply and clamping behaves as if CLAMP_FRAGMENT_COLOR_ARB is set to FIXED_ONLY_ARB.

Calling CopyPixels or BlitFramebufferEXT will result in an INVALID_FRAMEBUFFER_OPERATION_EXT error if the objects bound to DRAW_FRAMEBUFFER_BINDING_EXT and READ_FRAMEBUFFER_BINDING_EXT are not "framebuffer complete" (section 4.4.4.2)."

Calling BlitFramebufferEXT will result in an INVALID_OPERATION error if <mask> includes DEPTH_BUFFER_BIT or STENCIL_BUFFER_BIT and the source and destination depth and stencil buffer formats do not match.

Modify the beginning of section 4.4.1 as follows:

"The default framebuffer for rendering and readback operations is provided by the windowing system. In addition, named framebuffer objects can be created and operated upon. The namespace for framebuffer objects is the unsigned integers, with zero reserved by the GL for the default framebuffer.

A framebuffer object is created by binding an unused name to DRAW_FRAMEBUFFER_EXT or READ_FRAMEBUFFER_EXT. The binding is effected by calling

```
    void BindFramebufferEXT(enum target, uint framebuffer);
```

with <target> set to the desired framebuffer target and <framebuffer> set to the unused name. The resulting framebuffer object is a new state vector, comprising all the state values listed in table 4.nnn, as well as one set of the state values listed in table 5.nnn for each attachment point of the framebuffer, set to the same initial values. There are MAX_COLOR_ATTACHMENTS_EXT color attachment points, plus one each for the depth and stencil attachment points.

BindFramebufferEXT may also be used to bind an existing framebuffer object to DRAW_FRAMEBUFFER_EXT or READ_FRAMEBUFFER_EXT. If the bind is successful no change is made to the state of the bound framebuffer object, and any previous binding to <target> is broken.

If a framebuffer object is bound to DRAW_FRAMEBUFFER_EXT or READ_FRAMEBUFFER_EXT, it becomes the target for rendering or readback operations, respectively, until it is deleted or another framebuffer is bound to the corresponding bind point. Calling BindFramebufferEXT with <target> set to FRAMEBUFFER_EXT binds the framebuffer to both DRAW_FRAMEBUFFER_EXT and READ_FRAMEBUFFER_EXT.

While a framebuffer object is bound, GL operations on the target to which it is bound affect the images attached to the bound framebuffer object, and queries of the target to which it is bound return state from the bound object. Queries of the values specified in table 6.31 (Implementation Dependent Pixel Depths) and table 8.nnn (Framebuffer-Dependent State Variables) are derived from the framebuffer object bound to DRAW_FRAMEBUFFER_EXT.

The initial state of DRAW_FRAMEBUFFER_EXT and READ_FRAMEBUFFER_EXT refers to the default framebuffer provided by the windowing system. In order that access to the default framebuffer is not lost, it is treated as a framebuffer object with the name of 0. The default framebuffer is therefore rendered to and read from while 0 is bound to the corresponding targets. On some implementations, the properties of the default framebuffer can change over time (e.g., in response to windowing system events such as attaching the context to a new windowing system drawable.)"

Change the description of DeleteFramebuffersEXT as follows:

"<framebuffers> contains <n> names of framebuffer objects to be deleted. After a framebuffer object is deleted, it has no attachments, and its name is again unused. If a framebuffer that is currently bound to one or more of the targets DRAW_FRAMEBUFFER_EXT or READ_FRAMEBUFFER_EXT is deleted, it is as though BindFramebufferEXT had been executed with the corresponding <target> and <framebuffer> zero. Unused names in <framebuffers> are silently ignored, as is the value zero."

In section 4.4.2.2, modify the first two sentences of the description of FramebufferRenderbufferEXT as follows:

"<target> must be DRAW_FRAMEBUFFER_EXT, READ_FRAMEBUFFER_EXT, or FRAMEBUFFER_EXT. If <target> is FRAMEBUFFER_EXT, it behaves as though DRAW_FRAMEBUFFER_EXT was specified. INVALID_OPERATION is generated if the value of the corresponding binding is zero."

In section 4.4.2.3, modify the first two sentences of the description of FramebufferTexturexDEXT as follows:

"In all three routines, <target> must be DRAW_FRAMEBUFFER_EXT, READ_FRAMEBUFFER_EXT, or FRAMEBUFFER_EXT. If <target> is FRAMEBUFFER_EXT, it behaves as though DRAW_FRAMEBUFFER_EXT was specified. INVALID_OPERATION is generated if the value of the corresponding binding is zero."

In section 4.4.4.2, modify the first sentence of the description of CheckFramebufferStatusEXT as follows:

"If <target> is not DRAW_FRAMEBUFFER_EXT, READ_FRAMEBUFFER_EXT or FRAMEBUFFER_EXT, INVALID_ENUM is generated. If <target> is FRAMEBUFFER_EXT, it behaves as though DRAW_FRAMEBUFFER_EXT was specified."

Modify section 4.4.4.3 as follows:

"Attempting to render to or read from a framebuffer which is not framebuffer complete will generate an INVALID_FRAMEBUFFER_OPERATION_EXT error."

Additions to Chapter 6 of the OpenGL 1.5 Specification (State and State Requests)

In section 6.1.3, modify the first sentence of the description of GetFramebufferAttachmentParameterivEXT as follows:

"<target> must be DRAW_FRAMEBUFFER_EXT, READ_FRAMEBUFFER_EXT or FRAMEBUFFER_EXT. If <target> is FRAMEBUFFER_EXT, it behaves as though DRAW_FRAMEBUFFER_EXT was specified."

GLX Protocol

```
    BlitFramebufferEXT
        2        44              rendering command length
        2        4330            rendering command opcode
        4        CARD32          source X0
        4        CARD32          source Y0
        4        CARD32          source X1
        4        CARD32          source Y1
        4        CARD32          destination X0
        4        CARD32          destination Y0
        4        CARD32          destination X1
        4        CARD32          destination Y1
        4        CARD32          mask
        4        ENUM            filter
```

Dependencies on ARB_color_buffer_float

The reference to CLAMP_FRAGMENT_COLOR_ARB in section 4.3.3 applies only if ARB_color_buffer_float is supported.

Errors

The error INVALID_FRAMEBUFFER_OPERATION_EXT is generated if BlitFramebufferEXT, DrawPixels, or CopyPixels is called while the draw framebuffer is not framebuffer complete.

The error INVALID_FRAMEBUFFER_OPERATION_EXT is generated if BlitFramebufferEXT, ReadPixels, CopyPixels, CopyTex{Sub}Image*, CopyColor{Sub}Table, or CopyConvolutionFilter* is called while the read framebuffer is not framebuffer complete.

The error INVALID_VALUE is generated by BlitFramebufferEXT if <mask> has any bits set other than those named by COLOR_BUFFER_BIT, DEPTH_BUFFER_BIT or STENCIL_BUFFER_BIT.

The error INVALID_OPERATION is generated if BlitFramebufferEXT is called and <mask> includes DEPTH_BUFFER_BIT or STENCIL_BUFFER_BIT and <filter> is not NEAREST.

The error INVALID_OPERATION is generated if BlitFramebufferEXT is called and <mask> includes DEPTH_BUFFER_BIT or STENCIL_BUFFER_BIT and the source and destination depth or stencil buffer formats do not match.

The error INVALID_ENUM is generated by BlitFramebufferEXT if <filter> is not LINEAR or NEAREST.

The error INVALID_OPERATION is generated if BlitFramebufferEXT is called within a Begin/End pair.

The error INVALID_ENUM is generated if BindFramebufferEXT, CheckFramebufferStatusEXT, FramebufferTexture{1D|2D|3D}EXT, FramebufferRenderbufferEXT, or GetFramebufferAttachmentParameterivEXT is called and <target> is not DRAW_FRAMEBUFFER_EXT, READ_FRAMEBUFFER_EXT or FRAMEBUFFER_EXT.

New State

    (modify table 3.nnn, "Framebuffer (state per framebuffer target binding
point)")

Get Value	Type	Get Command	Initial Ialue	Description	Section	Attribute
DRAW_FRAMEBUFFER_BINDING_EXT	Z+	GetIntegerv	0	framebuffer object bound to DRAW_FRAMEBUFFER_EXT	4.4.1	-
READ_FRAMEBUFFER_BINDING_EXT	Z+	GetIntegerv	0	framebuffer object to READ_FRAMEBUFFER_EXT	4.4.1	-

    Remove reference to FRAMEBUFFER_BINDING_EXT.

Sample Code

```
    /* Render to framebuffer object 2 */
    BindFramebufferEXT(DRAW_FRAMEBUFFER_EXT, 2);
    RenderScene();

    /* Blit contents of color buffer, depth buffer and stencil buffer
     * from framebuffer object 2 to framebuffer object 1.
     */
    BindFramebufferEXT(READ_FRAMEBUFFER_EXT, 2);
    BindFramebufferEXT(DRAW_FRAMEBUFFER_EXT, 1);
    BlitFramebufferEXT(0, 0, 640, 480,
                       0, 0, 640, 480,
                       GL_COLOR_BUFFER_BIT |
                       GL_DEPTH_BUFFER_BIT |
                       GL_STENCIL_BUFFER_BIT,
                       GL_NEAREST);

    /* Blit contents of color buffer from framebuffer object 1 to
     * framebuffer object 2, inverting the image in the X direction.
     */
    BindFramebufferEXT(READ_FRAMEBUFFER_EXT, 1);
    BindFramebufferEXT(DRAW_FRAMEBUFFER_EXT, 2);
    BlitFramebufferEXT(0, 0, 640, 480,
                       640, 0, 0, 480,
                       GL_COLOR_BUFFER_BIT,
                       GL_NEAREST);

    /* Blit color buffer from framebuffer object 1 to framebuffer
     * object 3 with a 2X zoom and linear filtering.
     */
    BindFramebufferEXT(READ_FRAMEBUFFER_EXT, 1);
    BindFramebufferEXT(DRAW_FRAMEBUFFER_EXT, 3);
    BlitFramebufferEXT(0, 0, 640, 480,
                       0, 0, 1280, 960,
                       GL_COLOR_BUFFER_BIT, GL_LINEAR);
```

Issues

```
    1) Should we pass in explicit source/dest rects instead of using
       the rasterpos/pixelzoom?

        Resolved: use explicit rects, so we don't need to perform
        multiple state changes.

    2) Should rects be (start,size) or (start,end)?

        Resolved: use (start,end).  This is a break from the past
        (scissor, viewport) but is more intuitive than allowing a
        negative size where mirrored zooms are desireable.

    3) What should we call the blit function?

        Resolved: BlitFramebufferEXT

    4) Should filtering apply to depth or stencil values?

        Resolved: No

    5) What happens if LINEAR is specified and DEPTH or STENCIL is in
       the mask?

        Resolved: Generate ERROR_INVALID_OPERATION

    6) What happens if READ_FRAMEBUFFER is NONE and a read is
       attempted?

        Resolved: Generate ERROR_INVALID_OPERATION

    7) Should we generalize binding point assignment with a single
       entry point and a parameter specifying read/write/whatever?

        Resolved: concensus leans toward separate Read/Draw entry
        points.

    8) Should we define READ_FRAMEBUFFER and DRAW_FRAMEBUFFER targets
       for BindFramebuffer instead of introducing a new level of
       indirection?

        Resolved: Yes.  Binding to the legacy target FRAMEBUFFER sets
        both DRAW_FRAMEBUFFER and READ_FRAMEBUFFER.  Querying
        FRAMEBUFFER_BINDING return the DRAW_FRAMEBUFFER_BINDING.

    9) What happens when a user queries framebuffer attributes,
       e.g. Get(RED_BITS)?  Is the result returned from
       READ_FRAMEBUFFER or DRAW_FRAMEBUFFER?  Do we need a new query?
       e.g.

       GetFramebufferParameteriv(int target, enum pname, int* value)

        Resolved: always return the value associated with the
        DRAW_FRAMEBUFFER.  Do not add a new query.
    10) How does Accum behave in the presence of separate READ/DRAW
        framebuffers?

        Resolved: Accum returns INVALID_OPERATION if the
        READ_FRAMEBUFFER and DRAW_FRAMEBUFFER bindings are not
        identical.

    11) Should blits be allowed between buffers of different bit sizes?

        Resolved: Yes, for color buffers only.  Attempting to blit
        between depth or stencil buffers of different size generates
        INVALID_OPERATION.

    12) Should we add support for multiple ReadBuffers, so that
        multiple color buffers may be copied with a single call to
        BlitFramebuffer?

        Resolved: No, we considered this but the behavior is awkward
        to define and the functionality is of limited use.

    13) How should BlitFramebuffer color space conversion be
        specified?  Do we allow context clamp state to affect the
        blit?

        Resolved: Blitting to a fixed point buffer always clamps,
        blitting to a floating point buffer never clamps.  The context
        state is ignored.

    14) Should overlapped blits be allowed?  Should they be guaranteed
        to work?

        Resolved: Overlapping blits are allowed but are undefined.
```

Revision History

```
    Revision 14, 2006/09/29
      - Changed the resolution of issue 12 to reflect the working
        group decision to abandon ReadBuffers.
      - Eliminated issues 15, 16 and 17 as they are no longer relevent.
      - Changed the resolution of issue 14 and the corresponding spec
        language to indicate that the result of an overlapping blit is
        undefined.
      - Changed the spec language to clarify that the lower bound of a
        blit rectangle is inclusive while the upper bound is
        exclusive.
      - Added a sample showing an inverted blit, to clarify the pixel
        addressing rules.
      - Clarified spec language and error behavior to indicate that
        blitting DEPTH and STENCIL buffers with LINEAR filtering is
        always disallowed, whether or not the blit is scaling.
    Revision 13, 2006/06/01 (Jeff Juliano)
      - Clarify errors generated when read and draw framebuffers are
        incomplete.
    Revision 12, 2005/12/22 (Jon Leech)
      - Assigned enumerant values. Add return type to BlitFramebufferEXT.
        Note INVALID_ENUM error if filter is not LINEAR or NEAREST.
    Revision 11, 2005/12/14
```

```
      - Added several missing conditions to the Errors section.
      - Changed status to "Complete".
    Revision 10, 2005/11/6
      - Removed all ReadBuffers discussion, as this functionality will
        be deferred.  Issues 15-17 are hereafter irrelevent.
    Revision 9, 2005/10/31
      - Resolved issue 16 and updated language to reflect this decision.
      - Minor language changes per feedback.
      - Added issue 17 and resolution, although language does not reflect this.
    Revision 8, 2005/10/20
      - Added ReadBuffersEXT language
      - Removed some redundant language in ReadBuffer
      - Re-opened issue 15 for further consideration
      - Added issue 16
    Revision 7, 2005/10/7
      - Added issues 13 and 14, and resolution for 11, 13, and 14.
      - Added dependency on ARB_color_buffer_float.
      - Removed multisample language, now covered in
        EXT_framebuffer_multisample.
      - Added framebuffer incomplete error language to spec proper.
      - Alias DRAW_FRAMEBUFFER_BINDING_EXT to FRAMEBUFFER_BINDING_EXT.
      - Updated Overview text to reflect the resolution to issue 8.
    Revision 6, 2005/9/26
      - Moved issues to the end, per new conventions.
      - Added new language referring to DRAW_FRAMEBUFFER and
        READ_FRAMEBUFFER bind points to sections 4.1.1, 4.4.1,
        4.4.2.2, 4.4.2.3, 4.4.4.2, 6.1.3 and Errors, and updated the
        example code, per resolution of issue 8.
      - Added language in section 4.4.1 specifying Get behavior, per
        resolution of issue 9.
      - Added language to section 4.2.4 describing new error behavior
        for Accum, per resolution of issue 10.
      - Added language to section 4.3.3 describing color format
        conversion, per resolution of issue 11.
    Revision 5, 2005/9/6
      - Added issues 8 - 11
      - Minor edits from reviewer feedback
    Revision 4, 2005/9/5
      - Added chapter 4 intro section
      - Added errors and state table information
      - Added sample code
      - fixed typos
    Revision 3, 2005/8/29
      - Converted to spec template
    Revision 2, 2005/7/18
      - Lots of new issues added and resolved
    Revision 1, 2005/7/5
      - Initial draft
```

Status

    Complete
    Approved by the ARB "superbuffers" Working Group on November 8, 2005

Version

    Last Modified Date: November 6, 2006
    Revision: #6c

Number

    317

Dependencies

    Requires GL_EXT_framebuffer_object.

    Requires GL_EXT_framebuffer_blit.

    Written based on the wording of the OpenGL 1.5 specification.

Overview

    This extension extends the EXT_framebuffer_object framework to
    enable multisample rendering.

    The new operation RenderbufferStorageMultisampleEXT() allocates
    storage for a renderbuffer object that can be used as a multisample
    buffer. A multisample render buffer image differs from a

single-sample render buffer image in that a multisample image has a number of SAMPLES that is greater than zero. No method is provided for creating multisample texture images.

All of the framebuffer-attachable images attached to a framebuffer object must have the same number of SAMPLES or else the framebuffer object is not "framebuffer complete". If a framebuffer object with multisample attachments is "framebuffer complete", then the framebuffer object behaves as if SAMPLE_BUFFERS is one.

In traditional multisample rendering, where DRAW_FRAMEBUFFER_BINDING_EXT is zero and SAMPLE_BUFFERS is one, the GL spec states that "the color sample values are resolved to a single, displayable color each time a pixel is updated." There are, however, several modern hardware implementations that do not actually resolve for each sample update, but instead postpones the resolve operation to a later time and resolve a batch of sample updates at a time. This is OK as long as the implementation behaves "as if" it had resolved a sample-at-a-time. Unfortunately, however, honoring the "as if" rule can sometimes degrade performance.

In contrast, when DRAW_FRAMEBUFFER_BINDING_EXT is an application-created framebuffer object, MULTISAMPLE is enabled, and SAMPLE_BUFFERS is one, there is no implicit per-sample-update resolve. Instead, the application explicitly controls when the resolve operation is performed. The resolve operation is affected by calling BlitFramebufferEXT (provided by the EXT_framebuffer_blit extension) where the source is a multisample application-created framebuffer object and the destination is a single-sample framebuffer object (either application-created or window-system provided).

This design for multisample resolve more closely matches current hardware, but still permits implementations which choose to resolve a single sample at a time. If hardware that implementes the multisample resolution "one sample at a time" exposes EXT_framebuffer_multisample, it could perform the implicit resolve to a driver-managed hidden surface, then read from that surface when the application calls BlitFramebufferEXT.

Another motivation for granting the application explicit control over the multisample resolve operation has to do with the flexibility afforded by EXT_framebuffer_object. Previously, a drawable (window or pbuffer) had exclusive access to all of its buffers. There was no mechanism for sharing a buffer across multiple drawables. Under EXT_framebuffer_object, however, a mechanism exists for sharing a framebuffer-attachable image across several framebuffer objects, as well as sharing an image between a framebuffer object and a texture. If we had retained the "implicit" resolve from traditional multisampled rendering, and allowed the creation of "multisample" format renderbuffers, then this type of sharing would have lead to two problematic situations:

* Two contexts, which shared renderbuffers, might perform competing resolve operations into the same single-sample buffer with ambiguous results.

  * It would have introduced the unfortunate ability to use the
    single-sample buffer as a texture while MULTISAMPLE is ENABLED.

By using the BlitFramebufferEXT from EXT_framebuffer_blit as an explicit resolve to serialize access to the multisampeld contents and eliminate the implicit per-sample resolve operation, we avoid both of these problems.

Issues

Breaking from past convention, the issues section has been moved to the end of the document. It can be found after Examples, before Revision History.

New Procedures and Functions

```
void RenderbufferStorageMultisampleEXT(
        enum target, sizei samples,
        enum internalformat,
        sizei width, sizei height);
```

New Types

None.

New Tokens

Accepted by the <pname> parameter of GetRenderbufferParameterivEXT:

```
RENDERBUFFER_SAMPLES_EXT            0x8CAB
```

Returned by CheckFramebufferStatusEXT:

```
FRAMEBUFFER_INCOMPLETE_MULTISAMPLE_EXT  0x8D56
```

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
MAX_SAMPLES_EXT                     0x8D57
```

Additions to Chapter 2 of the 1.5 Specification (OpenGL Operation)

None

Additions to Chapter 3 of the OpenGL 1.5 Specification (Rasterization)

None

Additions to Chapter 4 of the OpenGL 1.5 Specification (Per-Fragment Operations and the Framebuffer)

Add to 4.3.2 (Reading Pixels), right before the subsection titled "Obtaining Pixels form the Framebuffer":

"ReadPixels generates INVALID_OPERATION if READ_FRAMEBUFFER_BINDING (section 4.4) is non-zero, the read framebuffer is framebuffer complete, and the value of SAMPLE_BUFFERS for the read framebuffer is greater than zero."

Modify the following text to section 4.3.3, page 194, that was added to the definition of CopyPixels by EXT_framebuffer_blit:

"Finally, the behavior of several GL operations is specified "as if the arguments were passed to CopyPixels." These operations include: CopyTex{Sub}Image*, CopyColor{Sub}Table, and CopyConvolutionFilter*. INVALID_FRAMEBUFFER_OPERATION_EXT will be generated if an attempt is made to execute one of these operations, or CopyPixels, while the object bound to READ_FRAMEBUFFER_BINDING_EXT (section 4.4) is not "framebuffer complete" (as defined in section 4.4.4.2). INVALID_OPERATION will be generated if the object bound to READ_FRAMEBUFFER_BINDING_EXT is "framebuffer complete" and the value of SAMPLE_BUFFERS is greater than zero.

Furthermore, an attempt to execute CopyPixels will generate INVALID_FRAMEBUFFER_OPERATION_EXT while the object bound to DRAW_FRAMEBUFFER_BINDING_EXT (section 4.4) is not "framebuffer complete".

In 4.3.3 (Copying Pixels), add to the section describing BlitFramebuffer that was added by EXT_framebuffer_blit.

"If SAMPLE_BUFFERS for the read framebuffer is greater than zero and SAMPLE_BUFFERS for the draw framebuffer is zero, the samples corresponding to each pixel location in the source are converted to a single sample before being written to the destination.

If SAMPLE_BUFFERS for the read framebuffer is zero and SAMPLE_BUFFERS for the draw framebuffer is greater than zero, the value of the source sample is replicated in each of the destination samples.

If SAMPLE_BUFFERS for both the read and draw framebuffers are greater than zero, and the value of SAMPLES for the read framebuffer matches the value of SAMPLES for the draw framebuffer, the samples are copied without modification from the read framebuffer to the draw framebuffer. Otherwise, no copy is performed and an INVALID_OPERATION error is generated.

Furthermore, if SAMPLE_BUFFERS for either the read framebuffer or draw framebuffer is greater than zero and the dimensions of the source and destination rectangles provided to BlitFramebuffer are not identical, no copy is performed and an INVALID_OPERATION error is generated."

Modification to 4.4.2.1 (Renderbuffer Objects)

Add, just above the definition of RenderbufferStorageEXT:

"The command

```
    void RenderbufferStorageMultisampleEXT(
        enum target, sizei samples,
        enum internalformat,
        sizei width, sizei height);
```

establishes the data storage, format, dimensions, and number of samples of a renderbuffer object's image. <target> must be RENDERBUFFER_EXT. <internalformat> must be RGB, RGBA, DEPTH_COMPONENT, STENCIL_INDEX, or one of the internal formats from table 3.16 or table 2.nnn that has a base internal format of RGB, RGBA, DEPTH_COMPONENT, or STENCIL_INDEX. <width> and <height> are the dimensions in pixels of the renderbuffer. If either <width> or <height> is greater than MAX_RENDERBUFFER_SIZE_EXT, or if <samples> is greater than MAX_SAMPLES_EXT, then the error INVALID_VALUE is generated. If the GL is unable to create a data store of the requested size, the error OUT_OF_MEMORY is generated.

Upon success, RenderbufferStorageMultisampleEXT deletes any existing data store for the renderbuffer image and the contents of the data store after calling RenderbufferStorageMultisampleEXT are undefined. RENDERBUFFER_WIDTH_EXT is set to <width>, RENDERBUFFER_HEIGHT_EXT is set to <height>, and RENDERBUFFER_INTERNAL_FORMAT_EXT is set to <internalformat>.

If <samples> is zero, then RENDERBUFFER_SAMPLES_EXT is set to zero. Otherwise <samples> represents a request for a desired minimum number of samples. Since different implementations may support different sample counts for multisampled rendering, the actual number of samples allocated for the renderbuffer image is implementation dependent. However, the resulting value for RENDERBUFFER_SAMPLES_EXT is guaranteed to be greater than or equal to <samples> and no more than the next larger sample count supported by the implementation.

Sized Internal Format	Base Internal format	S Bits
STENCIL_INDEX1_EXT	STENCIL_INDEX	1
STENCIL_INDEX4_EXT	STENCIL_INDEX	4
STENCIL_INDEX8_EXT	STENCIL_INDEX	8
STENCIL_INDEX16_EXT	STENCIL_INDEX	16

Table 2.nnn Desired component resolution for each sized internal format that can be used only with renderbuffers.

A GL implementation may vary its allocation of internal component resolution based on any RenderbufferStorage parameter (except target), but the allocation and chosen internal format must not be a function of any other state and cannot be changed once they are established."

```
    Modify the definiton of RenderbufferStorageEXT as follows:

    "The command

        void RenderbufferStorageEXT(enum target, enum internalformat,
                                    sizei width, sizei height);

     is equivalent to calling RenderbufferStorageMultisampleEXT with
     <samples> equal to zero."
```

Modification to 4.4.4.2 (Framebuffer Completeness)

```
    Add an entry to the bullet list:

    * The value of RENDERBUFFER_SAMPLES_EXT is the same for all attached
      images.
      { FRAMEBUFFER_INCOMPLETE_MULTISAMPLE_EXT }

    Also add a paragraph to the end of the section:

    "The values of SAMPLE_BUFFERS and SAMPLES are derived from the
    attachments of the currently bound framebuffer object.  If the
    current DRAW_FRAMEBUFFER_BINDING_EXT is not "framebuffer complete",
    then both SAMPLE_BUFFERS and SAMPLES are undefined.  Otherwise,
    SAMPLES is equal to the value of RENDERBUFFER_SAMPLES_EXT for the
    attached images (which all must have the same value for
    RENDERBUFFER_SAMPLES_EXT).  Further, SAMPLE_BUFFERS is one if
    SAMPLES is non-zero.  Otherwise, SAMPLE_BUFFERS is zero.
```

Additions to Chapter 5 of the OpenGL 1.5 Specification (Special Functions)

```
    Added to section 5.4, as part of the discussion of which commands
    are not compiled into display lists:

    "Certain commands, when called while compiling a display list, are
    not compiled into the display list but are executed immediately.
    These are: ..., RenderbufferStorageMultisampleEXT..."
```

Additions to Chapter 6 of the OpenGL 1.5 Specification (State and State Requests)

Modification to 6.1.3 (Enumerated Queries):

```
    In the list of state query functions, modify the definition of
    GetRenderbufferParameterivEXT as follows:

    "void GetRenderbufferParameterivEXT(enum target, enum pname,
                                        int* params);

        <target> must be RENDERBUFFER_EXT.  <pname> must be one of the
        symbolic values in table 8.nnn.

        If the renderbuffer currently bound to <target> is zero, then
        INVALID_OPERATION is generated.

        Upon successful return from GetRenderbufferParameterivEXT, if
        <pname> is RENDERBUFFER_WIDTH_EXT, RENDERBUFFER_HEIGHT_EXT,
        RENDERBUFFER_INTERNAL_FORMAT_EXT, or RENDERBUFFER_SAMPLES_EXT,
        then <params> will contain the width in pixels, height in
        pixels, internal format, or number of samples, respectively, of
        the renderbuffer currently bound to <target>.

        Otherwise, INVALID_ENUM is generated."
```

GLX Protocol

RenderbufferStorageMultisampleEXT

```
        2       24              rendering command length
        2       4331            rendering command opcode
        4       ENUM            target
        4       CARD32          samples
        4       ENUM            internalformat
        4       CARD32          width
        4       CARD32          height
```

Dependencies on EXT_framebuffer_object

EXT_framebuffer_object is required.

Dependencies on EXT_framebuffer_blit

EXT_framebuffer_blit is required. Technically, EXT_framebuffer_blit would not be required to support multisampled rendering, except for the fact that it provides the only method of doing a multisample resovle from a multisample renderbuffer.

Errors

The error INVALID_OPERATION_EXT is generated if ReadPixels, CopyPixels, CopyTex{Sub}Image*, CopyColor{Sub}Table, or CopyConvolutionFilter* is called while READ_FRAMEBUFFER_BINDING_EXT is non-zero, the read framebuffer is framebuffer complete, and the value of SAMPLE_BUFFERS for the read framebuffer is greater than zero.

The error OUT_OF_MEMORY is generated when RenderbufferStorageMultisampleEXT cannot storage of the specified size.

If both the draw and read framebuffers are framebuffer complete and both have a value of SAMPLE_BUFFERS that is greater than zero, then the error INVALID_OPERATION is generated if BlitFramebufferEXT is called and the values of SAMPLES for the draw and read framebuffers do not match.

If either the draw or read framebuffer is framebuffer complete and has a value of SAMPLE_BUFFERS that is greater than zero, then the error INVALID_OPERATION is generated if BlitFramebufferEXT is called and the specified source and destination dimensions are not identical.

    If RenderbufferStorageMultisampleEXT is called with a value of
    <samples> that is greater than MAX_SAMPLES_EXT, then the error
    INVALID_VALUE is generated.

New State

    (add to table 8.nnn, "Renderbuffers (state per renderbuffer object)")

Get Value	Type	Get Command	Initial Value	Description	Section	Attribute
RENDERBUFFER_SAMPLES_EXT	Z+	GetRenderbufferParameterivEXT	0	number of samples	4.4.2.1	-

To the table added by EXT_framebuffer_object called "Framebuffer
Dependent Values", table 9.nnn, add the following new framebuffer
dependent state.

Get Value	Type	Get Command	Minimum Value	Description	Section	Attribute
MAX_SAMPLES_EXT	Z+	GetIntegerv	1	Maximum number of samples supported for multisampling	4.4.2.1	-

Usage Examples

    XXX add examples XXX

Issues

    *(1) Should this be a separate extension or should it be included in
          a revision of EXT_framebuffer_object?*

          RESOLVED, separate extension

             Resolved by consensus, May 9, 2005

          This extension requires EXT_framebuffer_object but the reverse
          is not true. In addition, the cross framebuffer copy operation
          that will be used to handle the multisample resolution
          operation may be generally useful for non-multisampled
          rendering, but is pretty much required for multisampled
          rendering to be useful. Since we don't want
          EXT_framebuffer_object to require that functionality either, we
          split EXT_framebuffer_multisample into its own extension.
          EXT_framebuffer_multisample might include the "cross
          framebuffer copy" operation or might simply require the
          presence of that third extension. See issue (8).

    (2) What happens when <samples> is zero or one?

          RESOLVED, 0 = single sample, 1 = minimum multisample

             Resolved by consensus, May 9, 2005

          Zero means single sample, as if RenderbufferStorageEXT had been
          called instead of RenderbufferStorageMultisampleEXT. One means
          minimum number of samples supported by implementation.

There was a question if one should mean the same thing as single-sample (one sample), or if it should mean the minimum supported number of samples for multisample rendering. The rules for rasterizing in "multisample" mode are different than "non-multisample" mode. In the end, we decided that some implementations may wish to support a "one-sample" multisample buffer to allow for multipass multisampling where the sample location can be varied either by the implementation or perhaps explicitly by a "multisample location" extension.

(3) Is ReadPixels (or CopyPixels or CopyTexImage) permitted when bound to a multisample framebuffer object?

RESOLVED, no

Resolved by consensus, prior to May 9, 2005

No, those operations will produce INVALID_OPERATION. To read the contents of a multisample framebuffer, it must first be "downsampled" into a non-multisample destination, then read from there. For downsample, see EXT_framebuffer_blit.

The concern is fallback due to out of memory conditions. Even if no memory is available to allocate a temporary buffer at the time ReadPixels is called, an implementation should be able to make this work by pre-allocating a small tile and doing the downsample in tiles, or by falling back to software to copy a pixel at a time.

(4) Does the resolution from <samples> to RENDERBUFFER_SAMPLES_EXT depend on any other parameters to RenderbufferStorageMultisampleEXT, or must a given value of <samples> always resolve to the same number of actual samples?

RESOLVED, no, further, user must get at least what they asked for, or Storage call fails:

Resolved by consensus, May 23, 2005

Given the routine,

```
void RenderbufferStorageMultisampleEXT(
        enum target, uint samples,
        enum internalformat,
        uint width, uint height);
```

If an implementation supports several sample counts (say, 2x, 4x, 8x multisample), and the user requests a sample count of <samples>, the implementation must do one of the following:

- succeed in giving the user exactly <samples>, or

- succeed in giving the user a number of samples greater than <samples> but no more than the next highest number of samples supported by the implementation, or

- fail the request to RenderbufferStorageMultisampleEXT with an OUT_OF_MEMORY error

(5) *Is an implementation allowed to create single-sample storage when RenderbufferStorageMultisampleEXT is called with <samples> larger than one?*

RESOLVED, no

Resolved by consensus, May 23, 2005

No, by resolution of issue (4) above, the user must get at least what they asked for or higher, which precludes getting a single sampled format if they asked for a multisampled format.

(6) *Should OUT_OF_MEMORY be generated when RenderbufferStorageMultisampleEXT cannot create storage of the requested size?*

RESOLVED, yes

Resolved by consensus, May 23, 2005

Yes. Success or failure is determined by <width>, <height>, <internalformat>, and <samples>, and the implementation can always return OUT_OF_MEMORY. Note that while an implementation may give a different internal format with either higher or lower resolution per component than the internal requested, by issue of resolution (4), it must give at least the number of samples requested or it must fail the RenderbufferStorageMultisampleEXT call.

Update from June 2006 ARB meeting:

The appropriate error for the case where the number of samples is larger than the maximum supported by the implementation is INVALID_VALUE. To allow an application to know the maximum legal value, we add a GetInteger query MAX_SAMPLES.

(7) *Is there a query for the maximum size of <samples>?*

RESOLVED, no

Resolved by consensus, May 23, 2005

There was some discussion about whether it was useful to return a maximum sample count supported by the implementation as a convenenience to the developer so that the developer doesn't need to try increasingly smaller counts until it finds one that succeeds. However, in the end we decided that this was essentially the same problem already faced by the pixel format selection code in the glX/wgl/agl layer and so we decided not to add any special solution to this problem for multisampling with the framebuffer object API.

```
    (8)  Does this extension require our new framebuffer-to-framebuffer
         copy extension, EXT_framebuffer_blit, or is it merely affected
         by the presence of that extension.

         RESOLVED, EXT_framebuffer_blit is required.

         EXT_framebuffer_multisample by itself enable the user to
         perform multisampled rendering.  However, you can't copy or
         read from a multisampled renderbuffer using {Read|Copy}Pixels
         or CopyTex{Sub}Image - as per issue (3).  Consequently, there
         is no way to actually use the results of multisampled rendering
         without EXT_framebuffer_blit.  That makes the
         EXT_framebuffer_multisample extension arguably kind of useless
         without the EXT_framebuffer_blit.

         However, the reverse is not true.  The EXT_framebuffer_blit is
         useful on its own, which is why it is a separate extension from
         this one.

         So we decided to state that EXT_framebuffer_multisample
         requires EXT_framebuffer_blit instead of merely stating that
         that extension affects this one.

    (9)  Is DrawPixels allowed when the draw framebuffer is multisample?

         RESOLVED, yes

         This is no different than DrawPixels to a multisample window
         (framebuffer zero).  Note that ReadPixels and CopyPixels are
         disallowed when the read framebuffer is multisample.
```

Revision History

```
    #6c, November 6, 2006: jjuliano
        - changes from June #6 merged back in

    #6b, October 13, 2006: Jon Leech
        - added token values for MAX_SAMPLES_EXT and
          FRAMEBUFFER_INCOMPLETE_MULTISAMPLE_EXT.

    #6a, September 6, 2006: jsandmel
        - added language describing MAX_SAMPLES query
        - clarified that RenderbufferStorageMultisampleEXT can fail
          with INVALID_VALUE if <samples> is greater than MAX_SAMPLES

    #6, June 1, 2006: jjuliano
        - add missing errors to Errors section
        - clarify the modifications to 4.3.2 and 4.3.3.
        - add issue 9 to document that multisample DrawPixels is allowed

    #5, December 22, 2005: Jon Leech
        - added GLX protocol, assigned enumerant values
    #4, September 28, 2005: jsandmel, jjuliano
        - moved the multisample languge from GL_EXT_framebuffer_blit to
          this spec.
        - added description of using BlitFramebufferEXT for resolving
          multisample buffer
        - added language referring to DRAW_/READ_FRAMEBUFFER_BINDING
          instead of just FRAMEBUFFER_BINDING.
        - minor updates to reflect new EXT_framebuffer_blit spec
          that provides the multisample resolve function
        - resolve issue (8)
        - rename framebuffer_object_multisample to
          framebuffer_multisample

    #3, May 26, 2005: jsandmel
        - added recent workgroup resolutions
        - resolved issues (4), (5), (6), (7) based on decisions from the
          work group on May 9 and 23, 2005
        - added issue (8), does this extension require our new
          cross-framebuffer copy extension?
        - removed MAX_RENDERBUFFER_SAMPLES_EXT enum as per work group
          decision - issue (7)
        - changed prototype for RenderbufferStorageMultisampleEXT to use
          sizei for sample count

    #2, May 16, 2005: jsandmel
        - revised to account for recent work group meeting decisions
        - removed erroneous inclusion of GenerateMipmaps as a new
          function
        - resolved issue (1), this will be a separate extension
        - resolved issue (2), zero means non-multisample, one means
          minimum number of samples

    #1, May 9, 2005: jjuliano
        - first revision

Status

    Complete.
    Approved by the ARB "superbuffers" Working Group on January 31, 2005.
    Despite being controlled by the ARB WG, this is not an officially
    approved ARB extension at this time, thus the "EXT" tag.

Version

Last Modified Date: April 5, 2006
Revision: #118

Number

310

Dependencies

OpenGL 1.1 is required.

WGL_ARB_make_current_read affects the definition of this extension.

GLX 1.3 / GLX_SGI_make_current_read affects the definition of this extension.

ATI_draw_buffers affects the definition of this extension.

ARB_draw_buffers affects the definition of this extension.

ARB_fragment_program affects the definition of this extension.

ARB_fragment_shader affects the definition of this extension.

ARB_texture_rectangle affects the definition of this extension.

ARB_vertex_shader affects the definition of this extension.

EXT_packed_depth_stencil affects the definition of this extension.

NV_float_buffer affects the definition of this extension.

NV_texture_shader affects the definition of this extension.

Written based on the wording of the OpenGL 1.5 specification.

Overview

This extension defines a simple interface for drawing to rendering destinations other than the buffers provided to the GL by the window-system.

In this extension, these newly defined rendering destinations are known collectively as "framebuffer-attachable images". This extension provides a mechanism for attaching framebuffer-attachable images to the GL framebuffer as one of the standard GL logical buffers: color, depth, and stencil. (Attaching a framebuffer-attachable image to the accum logical buffer is left for a future extension to define). When a framebuffer-attachable image is attached to the framebuffer, it is used as the source and destination of fragment operations as described in Chapter 4.

By allowing the use of a framebuffer-attachable image as a rendering destination, this extension enables a form of "offscreen" rendering. Furthermore, "render to texture" is supported by allowing the images of a texture to be used as framebuffer-attachable images. A particular image of a texture object is selected for use as a framebuffer-attachable image by specifying the mipmap level, cube map face (for a cube map texture), and z-offset (for a 3D texture) that identifies the image. The "render to texture" semantics of this extension are similar to performing traditional rendering to the framebuffer, followed immediately by a call to CopyTexSubImage. However, by using this extension instead, an application can achieve the same effect, but with the advantage that the GL can usually eliminate the data copy that would have been incurred by calling CopyTexSubImage.

This extension also defines a new GL object type, called a "renderbuffer", which encapsulates a single 2D pixel image. The image of renderbuffer can be used as a framebuffer-attachable image for generalized offscreen rendering and it also provides a means to support rendering to GL logical buffer types which have no corresponding texture format (stencil, accum, etc). A renderbuffer is similar to a texture in that both renderbuffers and textures can be independently allocated and shared among multiple contexts. The framework defined by this extension is general enough that support for attaching images from GL objects other than textures and renderbuffers could be added by layered extensions.

To facilitate efficient switching between collections of framebuffer-attachable images, this extension introduces another new GL object, called a framebuffer object. A framebuffer object contains the state that defines the traditional GL framebuffer, including its set of images. Prior to this extension, it was the window-system which defined and managed this collection of images, traditionally by grouping them into a "drawable". The window-system API's would also provide a function (i.e., wglMakeCurrent, glXMakeCurrent, aglSetDrawable, etc.) to bind a drawable with a GL context (as is done in the WGL_ARB_pbuffer extension). In this extension however, this functionality is subsumed by the GL and the GL provides the function BindFramebufferEXT to bind a framebuffer object to the current context. Later, the context can bind back to the window-system-provided framebuffer in order to display rendered content.

Previous extensions that enabled rendering to a texture have been much more complicated. One example is the combination of ARB_pbuffer and ARB_render_texture, both of which are window-system extensions. This combination requires calling MakeCurrent, an operation that may be expensive, to switch between the window and the pbuffer drawables. An application must create one pbuffer per renderable texture in order to portably use ARB_render_texture. An application must maintain at least one GL context per texture format, because each context can only operate on a single pixelformat or FBConfig. All of these characteristics make ARB_render_texture both inefficient and cumbersome to use.

EXT_framebuffer_object, on the other hand, is both simpler to use and more efficient than ARB_render_texture. The EXT_framebuffer_object API is contained wholly within the GL API and has no (non-portable) window-system components. Under EXT_framebuffer_object, it is not necessary to create a second GL context when rendering to a texture image whose format differs from that of the window. Finally, unlike the pbuffers of ARB_render_texture, a single framebuffer object can facilitate rendering to an unlimited number of texture objects.

Glossary of Helpful Terms

logical buffer:
One of the color, depth, or stencil buffers of the framebuffer.

framebuffer:
The collection of logical buffers and associated state defining where the output of GL rendering is directed.

texture:
an object which consists of one or more 2D arrays of pixel images and associated state that can be used as a source of data during the texture-mapping process described in section 3.8.

texture image:
one of the 2D arrays of pixels that are part of a texture object as defined in section 3.8. Texture images contain and define the texels of the texture object.

renderbuffer:
A new type of storage object which contains a single 2D array of pixels and associated state that can be used as a destination for pixel data written during the rendering process described in Chapter 4.

renderbuffer image:
The 2D array of pixels that is part of a renderbuffer object. A renderbuffer image contains and defines the pixels of the renderbuffer object.

framebuffer-attachable image:
A 2D pixel image that can be attached to one of the logical buffer attachment points of a framebuffer object. Texture images and renderbuffer images are two examples of framebuffer-attachable images.

attachment point:
The set of state which references a specific framebuffer-attachable image, and allows that framebuffer-attachable image to be used to store the contents of a logical buffer of a framebuffer object. There is an attachment point state vector for each color, depth, and stencil buffer of a framebuffer.

attach:
The act of connecting one object to another object.

An "attach" operation is similar to a "bind" operation in that both represent a reference to the attached or bound object for the purpose of managing object lifetimes and both

```
            enable manipulation of the state of the attached or bound
            object.

            However, an "attach" is also different from a "bind" in that
            "binding" an unused object creates a new object, while
            "attaching" does not.  Additionally, "bind" establishes a
            connection between a context and an object, while "attach"
            establishes a connection between two objects.

            Finally, if object "A" is attached to object "B" and object
            "B" is bound to context "C", then in most respects, we treat
            "A" as if it is <implicitly> bound to "C".

        framebuffer attachment completeness:
            Similar to texture "mipmap" or "cube" completeness from
            section 3.8.10, defines a minimum set of criteria for
            framebuffer attachment points.  (for complete definition,
            see section 4.4.4.1)

        framebuffer completeness:
            Similar to texture "mipmap cube completeness", defines a
            composite set of "completeness" requirements and
            relationships among the attached framebuffer-attachable
            images.  (for complete definition, see section 4.4.4.2)
```

Issues

    Breaking from past convention, the very large issues section has
    been moved to the end of the document. It can be found after
    Examples, before Revision History.

New Procedures and Functions

```
    boolean IsRenderbufferEXT(uint renderbuffer);
    void BindRenderbufferEXT(enum target, uint renderbuffer);
    void DeleteRenderbuffersEXT(sizei n, const uint *renderbuffers);
    void GenRenderbuffersEXT(sizei n, uint *renderbuffers);

    void RenderbufferStorageEXT(enum target, enum internalformat,
                                sizei width, sizei height);

    void GetRenderbufferParameterivEXT(enum target, enum pname, int *params);

    boolean IsFramebufferEXT(uint framebuffer);
    void BindFramebufferEXT(enum target, uint framebuffer);
    void DeleteFramebuffersEXT(sizei n, const uint *framebuffers);
    void GenFramebuffersEXT(sizei n, uint *framebuffers);

    enum CheckFramebufferStatusEXT(enum target);
    void FramebufferTexture1DEXT(enum target, enum attachment,
                                 enum textarget, uint texture,
                                 int level);
    void FramebufferTexture2DEXT(enum target, enum attachment,
                                 enum textarget, uint texture,
                                 int level);
    void FramebufferTexture3DEXT(enum target, enum attachment,
                                 enum textarget, uint texture,
                                 int level, int zoffset);

    void FramebufferRenderbufferEXT(enum target, enum attachment,
                                    enum renderbuffertarget, uint renderbuffer);

    void GetFramebufferAttachmentParameterivEXT(enum target, enum attachment,
                                                enum pname, int *params);

    void GenerateMipmapEXT(enum target);
```

New Types

    None.

New Tokens

```
    Accepted by the <target> parameter of BindFramebufferEXT,
    CheckFramebufferStatusEXT, FramebufferTexture{1D|2D|3D}EXT,
    FramebufferRenderbufferEXT, and
    GetFramebufferAttachmentParameterivEXT:

        FRAMEBUFFER_EXT                     0x8D40

    Accepted by the <target> parameter of BindRenderbufferEXT,
    RenderbufferStorageEXT, and GetRenderbufferParameterivEXT, and
    returned by GetFramebufferAttachmentParameterivEXT:

        RENDERBUFFER_EXT                    0x8D41

    Accepted by the <internalformat> parameter of
    RenderbufferStorageEXT:

        STENCIL_INDEX1_EXT                  0x8D46
        STENCIL_INDEX4_EXT                  0x8D47
        STENCIL_INDEX8_EXT                  0x8D48
        STENCIL_INDEX16_EXT                 0x8D49

    Accepted by the <pname> parameter of GetRenderbufferParameterivEXT:

        RENDERBUFFER_WIDTH_EXT              0x8D42

Additions to Chapter 2 of the 1.5 Specification (OpenGL Operation)

"The GL interacts with two classes of framebuffers: window-system-provided framebuffers and application-created framebuffers. There is always one window-system-provided framebuffer, while application-created framebuffers can be created as desired. These two types of framebuffer are distinguished primarily by the interface for configuring and managing their state.

The effects of GL commands on the window-system-provided framebuffer are ultimately controlled by the window-system that allocates framebuffer resources. It is the window-system that determines which portions of this framebuffer the GL may access at any given time and that communicates to the GL how those portions are structured. Therefore, there are no GL commands to configure the window-system-provided framebuffer. Similarly, display of framebuffer contents on a CRT monitor (including the transformation of individual framebuffer values by such techniques as gamma correction) is not addressed by the GL. Framebuffer configuration occurs outside of the GL in conjunction with the window-system.

The initialization of a GL context itself occurs when the window-system allocates a window for GL rendering and is influenced by the state of the window-system-provided framebuffer."

Additions to Chapter 3 of the OpenGL 1.5 Specification (Rasterization)

In section 3.6.4, page 102, add the following text to the definiton of DrawPixels:

"If the object bound to FRAMEBUFFER_BINDING_EXT is not "framebuffer complete" (as defined in section 4.4.4.2), then an attempt to call DrawPixels will generate the error INVALID_FRAMEBUFFER_OPERATION_EXT."

In section 3.8.8, add the following text immediately before the subsection "Mipmapping" on page 151:

"If all of the following conditions are satisfied, then the value of the selected Tau(ijk), Tau(ij), or Tau(i) in the above equations is undefined instead of referring to the value of the texel at location (i), (i,j), or (i,j,k). See Chapter 4 for discussion of framebuffer objects and their attachments.

* The current FRAMEBUFFER_BINDING_EXT names an application-created framebuffer object <F>.

* The texture is attached to one of the attachment points, <A>, of framebuffer object <F>.

```
  * TEXTURE_MIN_FILTER is NEAREST or LINEAR, and the value of
    FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT for attachment point
    <A> is equal to the value of TEXTURE_BASE_LEVEL

    -or-

    TEXTURE_MIN_FILTER is NEAREST_MIPMAP_NEAREST,
    NEAREST_MIPMAP_LINEAR, LINEAR_MIPMAP_NEAREST, or
    LINEAR_MIPMAP_LINEAR, and the value of
    FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT for attachment point
    <A> is within the the inclusive range from TEXTURE_BASE_LEVEL to
    q."
```

In subsection "Automatic Mipmap Generation" to section 3.8.8, replace the first paragraph with the following text:

"If the value of texture parameter GENERATE MIPMAP is TRUE and a change is made to the interior or border texels of the level[base] array of a mipmap by one of the texture image specification operations defined in sections 3.8.1 through 3.8.3, then a complete set of mipmap arrays (as defined in section 3.8.10) will be computed. Array levels level[base] + 1 through p are replaced with arrays derived from the modified level[base], regardless of their previous contents. All other mipmap arrays, including the level[base] array, are left unchanged by this computation."

Add a new subsection "Manual Mipmap Generation" to section 3.8.8, after "Automatic Mipmap Generation":

"Manual Mipmap Generation

Mipmaps can be generated manually with the command

```
  void GenerateMipmapEXT(enum target);
```

where <target> is one of TEXTURE_1D, TEXTURE_2D, TEXTURE_CUBE_MAP, or TEXTURE_3D. Mipmap generation affects the texture image attached to <target>. For cube map textures, INVALID_OPERATION is generated if the texture bound to <target> is not cube complete, as defined in section 3.8.10.

Mipmap generation replaces texture array levels level[base] + 1 through q with arrays derived from the level[base] array, as described above under Automatic Mipmap Generation. All other mipmap arrays, including the level[base] array, are left unchanged by this computation. For arrays in the range level[base] through q, inclusive, automatic and manual mipmap generation generate the same derived arrays, given identical level[base] arrays."

Modify the third paragraph of section 3.8.12, page 157, to read:

"Texture objects are deleted by calling

```
    void DeleteTextures( sizei n, uint *textures );
```

textures contains n names of texture objects to be deleted. After a texture object is deleted, it has no contents or dimensionality, and its name is again unused. If a texture that is currently bound to one of the targets TEXTURE 1D, TEXTURE 2D, TEXTURE 3D, or TEXTURE CUBE MAP is deleted, it is as though BindTexture had been executed with the same target and texture zero. Additionally, special care must be taken when deleting a texture if any of the images of the texture are attached to a framebuffer object. See section 4.4.2.3 for details.

Unused names in textures are silently ignored, as is the value zero."

Additions to Chapter 4 of the OpenGL 1.5 Specification (Per-Fragment Operations and the Framebuffer)

On page 170, in the introduction to chapter 4, modify the first three paragraphs to read as follows:

"The framebuffer consists of a set of pixels arranged as a two-dimensional array. The height and width of this array may vary from one GL implementation to another. For purposes of this discussion, each pixel in the framebuffer is simply a set of some number of bits. The number of bits per pixel may also vary depending on the particular GL implementation or context.

Further there are two classes of framebuffers: the default framebuffer supplied by the window-system-provided and application-created framebuffer objects. Every GL context has a single default window-system-provided framebuffer. Applications can optionally create additional non-displayable framebuffer objects. (For more information on application-created framebuffer objects see section 4.4)

Corresponding bits from each pixel in the framebuffer are grouped together into a bitplane; each bitplane contains a single bit from each pixel. These bitplanes are grouped into several logical buffers. These are the color, depth, stencil, and accumulation buffers. The color buffer actually consists of a number of buffers, and these color buffers serve related but slightly different purposes depending on whether the GL is bound to the default window-system-provided framebuffer or to an application-created framebuffer object.

For the default window-system-provided framebuffer, the color buffers are: the front left buffer, the front right buffer, the back left buffer, the back right buffer, and some number of auxiliary buffers. Typically, the contents of the front buffers are displayed on a color monitor while the contents of the back buffers are invisible. (Monoscopic contexts display only the front left buffer; stereoscopic contexts display both the front left and the front right buffers.) The contents of the auxiliary buffers are never visible. All color buffers must have the same number of bitplanes, although an implementation or context may choose not to provide right buffers, back buffers, or auxiliary buffers at all. Further, an implementation or context may not provide depth, stencil, or accumulation buffers.

For application-created framebuffer objects, the color buffers are not visible, and consequently the names of the color buffers are not related to a display device. The names of the color buffers of an application-created framebuffer object are: COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT. The names of the depth and stencil buffers are DEPTH_ATTACHMENT_EXT and STENCIL_ATTACHMENT_EXT. For more information about the buffers of an application-created framebuffer object, see section 4.4.2. To be considered framebuffer complete (see section 4.4.4), all color buffers attached to an application-created framebuffer object must have the same number of bitplanes. Depth and stencil buffers may optionally be attached to application-created framebuffers as well.

Color buffers consist of either unsigned integer color indices or R, G, B, and, optionally, A unsigned integer values. The number of bitplanes in each of the color buffers, the depth buffer, the stencil buffer, and the accumulation buffer is dependent on the currently bound framebuffer. For the default framebuffer, the number of bitplanes is fixed. For application-created framebuffer objects, however, the number of bitplanes in a given logical buffer may change if the state of the corresponding framebuffer attachment or attached image changes (see sections 4.4.2 and 4.4.5). If an accumulation buffer is provided, it must have at least as many bitplanes per R, G, and B color component as do the color buffers."

Add a new paragraph to the end of section 4.1.1, page 171:

"While an application-created framebuffer object is bound to FRAMEBUFFER_EXT, the pixel ownership test always passes. The pixels of application-created frambuffer objects are always owned by the GL, not the window system. Only while the window-system-provided framebuffer named zero is bound to FRAMEBUFFER_EXT does the window system control pixel ownership."

Change section 4.1.5, page 174, third paragraph, first two sentences to read as follows:

"<ref> is an integer reference value that is used in the unsigned stencil comparison. Stencil comparison operations and queries of <ref> use the value of <ref> clamped to the range [0, (2^s) - 1], where s is the current number of bits in the stencil buffer."

Replace the first three sentences of 4.1.10 "Logical Operation":

"Finally, a logical operation is applied between the incoming fragment's color or index values and the color or index values stored at the corresponding location in the framebuffer. The result replaces the values in the framebuffer at the fragment's (x[w], y[w]) coordinates. However, if the DRAW_BUFFERS state selects a single framebuffer-attachable image more than once, then an undefined value is written to those color buffers at the fragment's (x[w], y[x]) coordinates."

Change section 4.2.1, to read as follows:

"The first such operation is controlling the buffer into which color values are written. This is accomplished with

```
    void DrawBuffer( enum buf );
```

<buf> defines a buffer or set of buffers for writing. <buf> must be one of the values from tables 4.4 or 10.nnn. Otherwise, INVALID_ENUM is generated. In addition, acceptable values for <buf> depend on whether the GL is using the default window-system-provided framebuffer (i.e., FRAMEBUFFER_BINDING_EXT is zero), or an application-created framebuffer object (i.e., FRAMEBUFFER_BINDING_EXT is non-zero). In the initial state, the GL is bound to the the window-system-provided framebuffer. For more information about application-created framebuffer objects, see section 4.4.

If the GL is bound to the window-system-provided framebuffer, then <buf> must be one the values listed in table 4.4, which summarizes the constants and the buffers they indicate. In this case, <buf> is a symbolic constant specifying zero, one, two, or four buffers for writing. These constants refer to the four potentially visible buffers front left, front right, back left, and back right, and to the auxiliary buffers. Arguments other than AUXi that omit reference to LEFT or RIGHT refer to both left and right buffers. Arguments other than AUXi that omit reference to FRONT or BACK refer to both front and back buffers. AUXi enables drawing only to auxiliary buffer i. Each AUXi adheres to AUXi = AUX0 + i.

If the GL is bound to an application-created framebuffer object, <buf> must be one of the values listed in table 10.nnn, which summarizes the constants and the buffers they indicate. In this case, <buf> is a symbolic constant specifying a single color buffer for writing. Specifying COLOR_ATTACHMENTi_EXT enables drawing only to the image attached to the framebuffer at COLOR_ATTACHMENTi_EXT. Each COLOR_ATTACHMENTi_EXT adheres to COLOR_ATTACHMENTi_EXT = COLOR_ATTACHMENT0_EXT + i. The intial value of DRAW_BUFFER for application-created framebuffer objects is COLOR_ATTACHMENT0_EXT.

Symbolic Constant	Meaning
NONE	no buffer
COLOR_ATTACHMENT0	output fragment color to image attached at color attachment point 0
COLOR_ATTACHMENT1	output fragment color to image attached at color attachment point 1
...	...
COLOR_ATTACHMENTn	output fragment color to image attached at color attachment point n, where n is MAX_COLOR_ATTACHMENTS - 1

Table 10.nnn: Arguments to DrawBuffer(s) and ReadBuffer when the context is bound to an application-created framebuffer object, and the buffers they indicate

If the GL is bound to the window-system-provided framebuffer and DrawBuffer is supplied with a constant (other than NONE) that does not indicate any of the color buffers allocated to the GL context by the window-system (including those listed in table 10.nnn), then the error INVALID_OPERATION results.

If the GL is bound to the application-created framebuffer and DrawBuffer is supplied with a constant from table 4.4, or COLOR_ATTACHMENTm where m is greater than or equal to MAX_COLOR_ATTACHMENTS, then the error INVALID_OPERATION results.

If DrawBuffer is supplied with a constant that is neither legal for the window-system provided framebuffer nor legal for an application-created framebuffer object, then the error INVALID_ENUM results.

The command

```
    void DrawBuffers( sizei n, const enum *bufs );
```

defines the draw buffers to which all fragment colors are written. <n> specifies the number of buffers in <bufs>. <bufs> is a pointer to an array of symbolic constants specifying the buffer to which each fragment color is written.

Each enumerant listed in <bufs> must be one of the values from tables 10.nnn or 11.nnn. Otherwise, INVALID_ENUM is generated. Further, acceptable values for the constants in <bufs> depend on whether the GL is using the default window-system-provided framebuffer (i.e., FRAMEBUFFER_BINDING_EXT is zero), or an application-created framebuffer object (i.e., FRAMEBUFFER_BINDING_EXT is non-zero). For more information about application-created framebuffer objects, see section 4.4.

symbolic constant	front left	front right	back left	back right	aux i
NONE					
FRONT LEFT	X				
FRONT RIGHT		X			
BACK LEFT			X		
BACK RIGHT				X	
AUXi					X

Table 11.nnn: Arguments to DrawBuffers, when the context is bound to the window-system-provided framebuffer, and the buffers that they indicate.

If the GL is bound to the default window-system-provided framebuffer, then the each of the constants must be one of the values listed in table 11.nnn

If the GL is bound to an application-created framebuffer object, then each of the constants must be one of the values listed in table 10.nnn.

In both cases, the draw buffers being defined correspond in order to the respective fragment colors. The draw buffer for fragment colors beyond <n> is set to NONE.

The maximum number of draw buffers is implementation dependent and must be at least 1. The number of draw buffers supported can be queried by calling GetIntegerv with the symbolic constant MAX_DRAW_BUFFERS. INVALID_VALUE is generated if <n> is greater than MAX_DRAW_BUFFERS.

Except for NONE, a buffer may not appear more then once in the array pointed to by <bufs>. Specifying a buffer more then once will result in the error INVALID_OPERATION.

If fixed-function fragment shading is being performed, DrawBuffers specifies a set of draw buffers into which the fragment color is written.

If a fragment shader writes to "gl_FragColor", DrawBuffers specifies a set of draw buffers into which the single fragment color defined by "gl_FragColor" is written. If a fragment shader writes to gl FragData, DrawBuffers specifies a set of draw buffers into which each of the multiple fragment colors defined by "gl_FragData" are separately written. If a fragment shader writes to neither gl FragColor nor "gl_FragData", the values of the fragment colors following shader execution are undefined, and may differ for each fragment color.

For both window-system-provided and application-created framebuffers, the constants FRONT, BACK, LEFT, RIGHT, and FRONT_AND_BACK are not valid in the <bufs> array passed to DrawBuffers, and will result in the error INVALID_OPERATION. This restriction is because these constants may themselves refer to multiple buffers, as shown in table 4.4.

If the GL is bound to the window-system-provided framebuffer and DrawBuffers is supplied with a constant (other than NONE) that does not indicate any of the color buffers allocated to the GL context by the window-system, then the error INVALID_OPERATION results.

If the GL is bound to the application-created framebuffer and DrawBuffers is supplied with a constant from table 11.nnn, or COLOR_ATTACHMENTm where m is greater than or equal to MAX_COLOR_ATTACHMENTS, then the error INVALID_OPERATION results.

If DrawBuffers is supplied with a constant that is neither legal for the window-system provided framebuffer nor legal for an application-created framebuffer object, then the error INVALID_ENUM results.

Indicating a buffer or buffers using DrawBuffer or DrawBuffers causes subsequent pixel color value writes to affect the indicated buffers.

Specifying NONE as the draw buffer for a fragment color will inhibit that fragment color from being written to any buffer.

Monoscopic contexts include only left buffers, while stereoscopic contexts include both left and right buffers. Likewise, single buffered contexts include only front buffers, while double buffered contexts include both front and back buffers. The type of context is selected at GL initialization.

The state required to handle color buffer selection is an integer for each supported fragment color. For the default window-system-provided framebuffer, in the initial state, the draw buffer for fragment color zero is FRONT if there are no back buffers; otherwise it is BACK. For application-created framebuffer objects, the initial value of draw buffer for fragment color zero is COLOR_ATTACHMENT0_EXT. For both the window-system-provided framebuffer and application-created framebuffers, the initial state of draw buffers for fragment colors other then zero is NONE."

Modify section 4.2.2, page 185, third paragraph to read as follows:

"The command

```
        void StencilMask( uint mask );
```

controls the writing of particular bits into the stencil planes. The least significant s bits of mask comprise an integer mask (s is the number of bits in the stencil buffer), just as for IndexMask. The initial state is for the stencil plane mask to be 32 ones."

In section 4.3.2, page 190, modify the first two paragraphs of the definition of ReadBuffer to read as follows:

"The command

```
     void ReadBuffer( enum src );
```

takes a symbolic constant as argument. <src> must be one of the values from tables 4.4 or 10.nnn. Otherwise, INVALID_ENUM is generated. Further, the acceptable values for <src> depend on whether the GL is using the default window-system-provided framebuffer (i.e., FRAMEBUFFER_BINDING_EXT is zero), or an application-created framebuffer object (i.e., FRAMEBUFFER_BINDING_EXT is non-zero). For more information about application-created framebuffer objects, see section 4.4.

If the object bound to FRAMEBUFFER_BINDING_EXT is not "framebuffer complete" (as defined in section 4.4.4.2), then ReadPixels generates the error INVALID_FRAMEBUFFER_OPERATION_EXT. If ReadBuffer is supplied with a constant that is neither legal for the window-system provided framebuffer, nor legal for an application-created framebuffer object, then the error INVALID_ENUM results.

When FRAMEBUFFER_BINDING_EXT is zero, i.e. the default window-system-provided framebuffer, <src> must be one of the values listed in table 4.4. FRONT and LEFT refer to the front left buffer, BACK refers to the back left buffer, and RIGHT refers to the front right buffer. The other constants correspond directly to the buffers that they name. If the requested buffer is missing, then the error INVALID_OPERATION is generated. For the default window-system-provided framebuffer, the initial setting for ReadBuffer is FRONT if there is no back buffer and BACK otherwise.

When the GL is using an application-created framebuffer object, <src> must be one of the values listed in table 10.nnn, including NONE. In a manner analogous to how the DRAW_BUFFERs state is handled, specifying COLOR_ATTACHMENTi_EXT enables reading from the image attached to the framebuffer at COLOR_ATTACHMENTi_EXT. ReadPixels generates INVALID_OPERATION if it attempts to select a color buffer while READ_BUFFER is NONE. For application-created framebuffer objects, the initial setting for ReadBuffer is COLOR_ATTACHMENT0_EXT.

ReadPixels obtains values from the selected buffer from each pixel with lower left hand corner at (x+i, y+j) for (0 <= i < width) and (0 <= j < height); this pixel is said to be the ith pixel in the jth row. If any of these pixels lies outside of the window allocated to the current GL context, or outside of the image attached to the currently bound framebuffer object, then the values obtained for those pixels are undefined. When FRAMEBUFFER_BINDING_EXT is zero, results are also undefined for individual pixels that are not owned by the current context. Otherwise, ReadPixels obtains values from the selected buffer, regardless of how those values were placed there."

In section 4.3.2, "Reading Pixels", add a paragraph before "Conversion of RGBA values" on page 191:

"When FRAMEBUFFER_BINDING is non-zero, the red, green, blue, and alpha values are obtained by first reading the internal component values of the corresponding value in the image attached to the selected logical buffer. The internal component values are converted to red, green, blue, and alpha values as specified in the row of table 12.nnn corresponding to the internal format of the image attached to READ_BUFFER."

Add the following text to section 4.3.3, page 194, inside the definiton of CopyPixels:

"Furthermore, the behavior of several GL operations is specified "as if the arguments were passed to CopyPixels." These operations include: CopyTex{Sub}Image*, CopyColor{Sub}Table, and CopyConvolutionFilter*. INVALID_FRAMEBUFFER_OPERATION_EXT will be generated if an attempt is made to execute one of these operations, or CopyPixels, while the object bound to FRAMEBUFFER_BINDING_EXT is not "framebuffer complete" (as defined in section 4.4.4.2)."

Add a new section "Framebuffer Objects" after section 4.3:

"4.4 Framebuffer Objects

As described in chapters 1 and 2, GL renders into (and reads values from) a framebuffer. GL defines two classes of framebuffers: window-system-provided framebuffers and application-created framebuffers. For each GL context, there is a single framebuffer provided by the window-system, and there may also be one or more framebuffer objects created and managed by the application.

By default, the GL uses the window-system-provided framebuffer. The storage, dimensions, allocation, and format of the images attached to this framebuffer are managed entirely by the window-system. Consequently, the state of the window-system-provided framebuffer, including its images, can not be changed by the GL, nor can the window-system-provided framebuffer itself, or its images, be deleted by the GL.

The routines described in the following sections, however, can be used to create, destroy, and modify the state and attachments of application-created framebuffer objects.

Application-created framebuffer objects encapsulate the state of a framebuffer in a similar manner to the way texture objects encapsulate the state of a texture. In particular, a framebuffer object encapsulates state necessary to describe a collection of color, depth, stencil, accum, and aux logical buffers. For each logical buffer, a framebuffer-attachable image can be attached to the framebuffer to store the rendered output for that logical buffer. Examples of framebuffer-attachable images include texture images and renderbuffer images. Renderbuffers are described further in section 4.4.2.1

By allowing the images of a renderbuffer to be attached to a framebuffer, the GL provides a mechanism to support "off-screen" rendering. Further, by allowing the images of a texture to be attached to a framebuffer, the GL provides a mechanism to support "render to texture".

4.4.1 Binding and Managing Framebuffer Objects

The operations described in chapter 4 affect the images attached to the framebuffer object bound to the target FRAMEBUFFER_EXT. By default, framebuffer bound to the target FRAMEBUFFER_EXT is zero, specifying the default implementation dependent framebuffer provided by the windowing system. When the framebuffer bound to target FRAMEBUFFER_EXT is not zero, but instead names an application-created framebuffer object, then the operations described in chapter 4 affect the application-created framebuffer object rather than the default framebuffer.

The namespace for framebuffer objects is the unsigned integers, with zero reserved by the GL to refer to the default framebuffer. A framebuffer object is created by binding an unused name to the target FRAMEBUFFER_EXT. The binding is effected by calling

```
    void BindFramebufferEXT(enum target, uint framebuffer);
```

with <target> set to FRAMEBUFFER_EXT and <framebuffer> set to the unused name. The resulting framebuffer object is a new state vector, comprising all the state values listed in table 4.nnn, as well as one set of the state values listed in table 5.nnn for each attachment point of the framebuffer. There are MAX_COLOR_ATTACHMENTS_EXT color attachment points, plus one each for the depth and stencil attachment points.

BindFramebufferEXT may also be used to bind an existing framebuffer object to <target>. If the bind is successful no change is made to the state of the bound framebuffer object and any previous binding to <target> is broken. The current FRAMEBUFFER_EXT binding can be queried using GetIntegerv(FRAMEBUFFER_BINDING_EXT).

While a framebuffer object is bound to the target FRAMEBUFFER_EXT, GL operations on the target to which it is bound affect the images attached to the bound framebuffer object, and queries of the target to which it is bound return state from the bound object. In particular, queries of the values specified in table 6.31 (Implementation Dependent Pixel Depths) and table 8.nnn (Framebuffer-Dependent State Variables) are derived from the currently bound framebuffer object. The framebuffer object bound to the target FRAMEBUFFER_EXT is used as the destination of fragment operations and as the source of pixel reads such as ReadPixels, as described in chapter 4.

In the initial state, the reserved name zero is bound to the target FRAMEBUFFER_EXT. There is no application-created framebuffer object corresponding to the name zero. Instead, the name zero refers to the window-system-provided framebuffer. All queries and operations on the framebuffer while the name zero is bound to the target FRAMEBUFFER_EXT operate on this default framebuffer. On some implementations, the properties of the default window-system-provided framebuffer can change over time (e.g., in response to window-system events such as attaching the context to a new window-system drawable.)

Application-created framebuffer objects (i.e., those with a non-zero name) differ from the default window-system-provided framebuffer in a few important ways. First and foremost, unlike the window-system-provided framebuffer, application-created-framebuffers have modifiable attachment points for each logical buffer in the framebuffer. Framebuffer-attachable images can be attached to and detached from these attachment points, which are described further in section 4.4.2. Also, the size and format of the images attached to application-created framebuffers are controlled entirely within the GL interface, and are not affected by window-system events, such as pixel format selection, window resizes, and display mode changes.

Additionally, when rendering to or reading from an application created-framebuffer object,

- The pixel ownership test always succeeds. In other words, application-created framebuffer objects own all of their pixels.

- There are no visible color buffer bitplanes. This means there is no color buffer corresponding to the back, front, left, or right color bitplanes.

- The only color buffer bitplanes are the ones defined by the framebuffer attachment points named COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT.

- The only depth buffer bitplanes are the ones defined by the framebuffer attachment point DEPTH_ATTACHMENT_EXT.

- The only stencil buffer bitplanes are the ones defined by the framebuffer attachment point STENCIL_ATTACHMENT_EXT.

- There is no multisample buffer so the value of the implementation-dependent state variables SAMPLES and SAMPLE_BUFFERS are both 0

- There are no accum buffer bitplanes, so the value of the implementation-dependent state variables ACCUM_RED_BITS, ACCUM_GREEN_BITS, ACCUM_BLUE_BITS, and ACCUM_ALPHA_BITS, are all zero.

- There are no AUX buffer bitplanes, so the value of the implementation-dependent state variable AUX_BUFFERS is zero.

Framebuffer objects are deleted by calling

```
  void DeleteFramebuffersEXT(sizei n, uint *framebuffers);
```

<framebuffers> contains <n> names of framebuffer objects to be deleted. After a framebuffer object is deleted, it has no attachments, and its name is again unused. If a framebuffer that is currently bound to the target FRAMEBUFFER_EXT is deleted, it is as though BindFramebufferEXT had been executed with the <target> of FRAMEBUFFER_EXT and <framebuffer> of zero. Unused names in <framebuffers> are silently ignored, as is the value zero.

The command

```
  void GenFramebuffersEXT(sizei n, uint *ids);
```

returns <n> previously unused framebuffer object names in <ids>. These names are marked as used, for the purposes of GenFramebuffersEXT only, but they acquire state and type only when they are first bound, just as if they were unused.

4.4.2 Attaching Images to Framebuffer Objects

Framebuffer-attachable images may be attached to, and detached from, application-created framebuffer objects. In contrast, the image attachments of the window-system-provided framebuffer may not be changed by the GL.

A single framebuffer-attachable image may be attached to multiple application-created framebuffer objects, potentially avoiding some data copies, and possibly decreasing memory consumption.

For each logical buffer, the framebuffer object stores a set of state which defines the logical buffer's "attachment point". The "attachment point" state contains enough information to identify the single image attached to the attachment point, or to indicate that no image is attached. The per-logical buffer "attachment point" state is listed in table 5.nnn

There are two types of framebuffer-attachable images: the image of a renderbuffer object, and an image of a texture object.

4.4.2.1 Renderbuffer Objects

A renderbuffer is a data storage object containing a single image of a renderable internal format. GL provides the methods described below to allocate and delete a renderbuffer's image, and to attach a renderbuffer's image to a framebuffer object.

The name space for renderbuffer objects is the unsigned integers, with zero reserved for the GL. A renderbuffer object is created by binding an unused name to RENDERBUFFER_EXT. The binding is effected by calling

```
    void BindRenderbufferEXT( enum target, uint renderbuffer );
```

with <target> set to RENDERBUFFER_EXT and <renderbuffer> set to the unused name. If <renderbuffer> is not zero, then the resulting renderbuffer object is a new state vector, initialized with a zero-sized memory buffer, and comprising the state values listed in Table 8.nnn. Any previous binding to <target> is broken.

BindRenderbufferEXT may also be used to bind an existing renderbuffer object. If the bind is successful, no change is made to the state of the newly bound renderbuffer object, and any previous binding to <target> is broken.

While a renderbuffer object is bound, GL operations on the target to which it is bound affect the bound renderbuffer object, and queries of the target to which a renderbuffer object is bound return state from the bound object.

The name zero is reserved. A renderbuffer object cannot be created with the name zero. If <renderbuffer> is zero, then any previous binding to <target> is broken and the <target> binding is restored to the initial state.

In the initial state, the reserved name zero is bound to RENDERBUFFER_EXT. There is no renderbuffer object corresponding to the name zero, so client attempts to modify or query renderbuffer state for the target RENDERBUFFER_EXT while zero is bound will generate GL errors, as described in section 6.1.3.

Using GetIntegerv, the current RENDERBUFFER_EXT binding can be queried as RENDERBUFFER_BINDING_EXT.

Renderbuffer objects are deleted by calling

```
    void DeleteRenderbuffersEXT( sizei n, const uint *renderbuffers );
```

where <renderbuffers> contains n names of renderbuffer objects to be deleted. After a renderbuffer object is deleted, it has no contents, and its name is again unused. If a renderbuffer that is currently bound to RENDERBUFFER_EXT is deleted, it is as though BindRenderbufferEXT had been executed with the <target> RENDERBUFFER_EXT and <name> of zero. Additionally, special care must be taken when deleting a renderbuffer if the image of the renderbuffer is attached to a framebuffer object. (See section 4.4.2.2 for details). Unused names in <renderbuffers> are silently ignored, as is the value zero.

The command

```
    void GenRenderbuffersEXT( sizei n, uint *renderbuffers );
```

returns <n> previously unused renderbuffer object names in <renderbuffers>. These names are marked as used, for the purposes of GenRenderbuffersEXT only, but they acquire renderbuffer state only when they are first bound, just as if they were unused.

The command

```
    void RenderbufferStorageEXT(enum target, enum internalformat,
                                sizei width, sizei height);
```

establishes the data storage, format, and dimensions of a renderbuffer object's image. <target> must be RENDERBUFFER_EXT. <internalformat> must be color-renderable, depth-renderable, or stencil-renderable (as defined in section 4.4.4). <width> and <height> are the dimensions in pixels of the renderbuffer. If either <width> or <height> is greater than MAX_RENDERBUFFER_SIZE_EXT, the the error INVALID_VALUE is generated. If the GL is unable to create a data store of the requested size, the error OUT_OF_MEMORY is generated. RenderbufferStorageEXT deletes any existing data store for the renderbuffer and the contents of the data store after calling RenderbufferStorageEXT are undefined.

Sized Internal Format	Base Internal format	S Bits
STENCIL_INDEX1_EXT	STENCIL_INDEX	1
STENCIL_INDEX4_EXT	STENCIL_INDEX	4
STENCIL_INDEX8_EXT	STENCIL_INDEX	8
STENCIL_INDEX16_EXT	STENCIL_INDEX	16

Table 2.nnn Desired component resolution for each sized internal format that can be used only with renderbuffers.

A GL implementation may vary its allocation of internal component resolution based on any RenderbufferStorage parameter (except target), but the allocation and chosen internal format must not be a function of any other state and cannot be changed once they are established. The actual resolution in bits of each component of the allocated image can be queried with GetRenderbufferParameteriv as described in section 6.1.3.

4.4.2.2 Attaching Renderbuffer Images to a Framebuffer

A renderbuffer can be attached as one of the logical buffers of the currently bound framebuffer object by calling

```
    void FramebufferRenderbufferEXT(enum target,
                                    enum attachment,
                                    enum renderbuffertarget,
                                    uint renderbuffer);
```

<target> must be FRAMEBUFFER_EXT. INVALID_OPERATION is generated if the current value of FRAMEBUFFER_BINDING_EXT is zero when FramebufferRenderbufferEXT is called. <attachment> should be set to one of the attachment points of the framebuffer listed in table 1.nnn. <renderbuffertarget> must be RENDERBUFFER_EXT and <renderbuffer> should be set to the name of the renderbuffer object to be attached to the framebuffer. <renderbuffer> must be either zero or the name of an existing renderbuffer object of type <renderbuffertarget>, otherwise INVALID_OPERATION is generated. If <renderbuffer> is zero, then the value of <renderbuffertarget> is ignored.

If <renderbuffer> is not zero and if FramebufferRenderbufferEXT is successful, then the renderbuffer named <renderbuffer> will be used as the logical buffer identified by <attachment> of the framebuffer currently bound to <target>. The value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT for the specified attachment point is set to RENDERBUFFER_EXT and the value of FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT is set to <renderbuffer>. All other state values of the attachment point specified by <attachment> are set to their default values listed in table 5.nnn. No change is made to the state of the renderbuffer object and any previous attachment to the <attachment> logical buffer of the framebuffer object bound to framebuffer <target> is broken. If, on the other hand, the attachment is not successful, then no change is made to the state of either the renderbuffer object or the framebuffer object.

Calling FramebufferRenderbufferEXT with the <renderbuffer> name zero will detach the image, if any, identified by <attachment>, in the framebuffer currently bound to <target>. All state values of the attachment point specified by <attachment> in the object bound to <target> are set to their default values listed in table 5.nnn.

If a renderbuffer object is deleted while its image is attached to one or more attachment points in the currently bound framebuffer, then it is as if FramebufferRenderbufferEXT() had been called, with a <renderbuffer> of 0, for each attachment point to which this image was attached in the currently bound framebuffer. In other words, this renderbuffer image is first detached from all attachment points in the currently bound framebuffer. Note that the renderbuffer image is specifically *not* detached from any non-bound framebuffers. Detaching the image from any non-bound framebuffers is the responsibility of the application.

```
Name of attachment
---------------------------------------------------------------------------------
COLOR_ATTACHMENT0_EXT ... COLOR_ATTACHMENTn_EXT (where n is from 0 to MAX_COLOR_ATTACHMENTS_EXT-1)
DEPTH_ATTACHMENT_EXT
STENCIL_ATTACHMENT_EXT
---------------------------------------------------------------------------------
```

Table 1.nnn: "List of framebuffer attachment points"

4.4.2.3 Attaching Texture Images to a Framebuffer

GL supports copying the rendered contents of the framebuffer into the images of a texture object through the use of the routines CopyTexImage{1D|2D}, and CopyTexSubImage{1D|2D|3D}. Additionally, GL supports rendering directly into the images of a texture object.

To render directly into a texture image, a specified image from a texture object can be attached as one of the logical buffers of the currently bound framebuffer object by calling one of the following routines, depending on the type of the texture:

```
    void FramebufferTexture1DEXT(enum target, enum attachment,
                                 enum textarget, uint texture,
                                 int level);
    void FramebufferTexture2DEXT(enum target, enum attachment,
                                 enum textarget, uint texture,
                                 int level);
    void FramebufferTexture3DEXT(enum target, enum attachment,
                                 enum textarget, uint texture,
                                 int level, int zoffset);
```

In all three routines, <target> must be FRAMEBUFFER_EXT. INVALID_OPERATION is generated if the current value of FRAMEBUFFER_BINDING_EXT is zero when FramebufferTexture{1D|2D|3D}EXT is called. <attachment> must be one of the attachment points of the framebuffer listed in table 1.nnn.

In all three routines, if <texture> is zero, then <textarget>, <level>, and <zoffset> are ignored. If <texture> is not zero, then <texture> must either name an existing texture object with an target of <textarget>, or <texture> must name an existing cube map texture and <textarget> must be one of: TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_Y, or TEXTURE_CUBE_MAP_NEGATIVE_Z. Otherwise, GL_INVALID_OPERATION is generated.

<level> specifies the mipmap level of the texture image to be attached to the framebuffer.

If <textarget> is TEXTURE_RECTANGLE_ARB, then <level> must be zero. If <textarget> is TEXTURE_3D, then <level> must be greater than or equal to zero and less than or equal to log base 2 of MAX_3D_TEXTURE_SIZE. If <textarget> is one of TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_Y, or TEXTURE_CUBE_MAP_NEGATIVE_Z, then <level> must be greater than or equal to zero and less than or equal to log base 2 of MAX_CUBE_MAP_TEXTURE_SIZE. For all other values of <textarget>, <level> must be greater than or equal to zero and no larger than log base 2 of MAX_TEXTURE_SIZE. Otherwise, INVALID_VALUE is generated.

<zoffset> specifies the z-offset of a 2-dimensional image within a 3-dimensional texture. INVALID_VALUE is generated if <zoffset> is larger than MAX_3D_TEXTURE_SIZE-1.

For FramebufferTexture1DEXT, if <texture> is not zero, then <textarget> must be TEXTURE_1D.

For FramebufferTexture2DEXT, if <texture> is not zero, then <textarget> must be one of: TEXTURE_2D, TEXTURE_RECTANGLE_ARB, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_Y, or TEXTURE_CUBE_MAP_NEGATIVE_Z.

For FramebufferTexture3DEXT, if <texture> is not zero, then <textarget> must be TEXTURE_3D.

If <texture> is not zero, and if FramebufferTexture{1D|2D|3D}EXT is successful, then the specified texture image will be used as the logical buffer identified by <attachment> of the framebuffer currently bound to <target>. The value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT for the specified attachment point is set to TEXTURE and the value of FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT is set to <texture>. Additionally, the value of FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL for the named attachment point is set to <level>. If <texture> is a cubemap texture then, the value of FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE the named attachment point is set to <textarget>. If <texture> is a 3D texture, then the value of FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET for the named attachment point is set to <zoffset>. All other state values of the attachment point specified by <attachment> are set to their default values listed in table 5.nnn. No change is made to the state of the texture object, and any previous attachment to the <attachment> logical buffer of the framebuffer object bound to framebuffer <target> is broken. If, on the other hand, the attachment is not successful, then no change is made to the state of either the texture object or the framebuffer object.

Calling FramebufferTexture{1D|2D|3D}EXT with <texture> name zero will detach the image identified by <attachment>, if any, in the framebuffer currently bound to <target>. All state values of the attachment point specified by <attachment> are set to their default values listed in table 5.nnn.

If a texture object is deleted while its image is attached to one or more attachment points in the currently bound framebuffer, then it is as if FramebufferTexture{1D|2D|3D}EXT() had been called, with a <texture> of 0, for each attachment point to which this image was attached in the currently bound framebuffer. In other words, this texture image is first detached from all attachment points in the currently bound framebuffer. Note that the texture image is specifically *not* detached from any other framebuffer objects.

Detaching the texture image from any other framebuffer objects is the responsibility of the application.

4.4.3 Rendering When an Image of a Bound Texture Object is Also Attached to the Framebuffer

Special precautions need to be taken to avoid attaching a texture image to the currently bound framebuffer while the texture object is currently bound and enabled for texturing. Doing so could lead to the creation of a "feedback loop" between the writing of pixels by the GL's rendering operations and the simultaneous reading of those same pixels when used as texels in the currently bound texture. In this scenario, the framebuffer will be considered framebuffer complete (see section 4.4.4), but the values of fragments rendered while in this state will be undefined. The values of texture samples may be undefined as well, as described in section 3.8.8.

Specifically, the values of rendered fragments are undefined if all of the following conditions are true:

- an image from texture object <T> is attached to the currently bound framebuffer at attachment point <A>, and

- the texture object <T> is currently bound to a texture unit <U>, and

- the current fixed-function texture state or programmable vertex and/or fragment processing state makes it possible(*) to sample from the texture object <T> bound to texture unit <U>

while either of the following conditions are true:

- the value of TEXTURE MIN FILTER for texture object <T> is NEAREST or LINEAR, and the value of FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT for attachment point <A> is equal to the value of TEXTURE_BASE_LEVEL for the texture object <T>, or

- the value of TEXTURE_MIN_FILTER for texture object <T> is one of NEAREST_MIPMAP_NEAREST, NEAREST_MIPMAP LINEAR, LINEAR MIPMAP_NEAREST, or LINEAR_MIPMAP_LINEAR, and the value of FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT for attachment point <A> is within the the range specified by the current values of TEXTURE_BASE_LEVEL to q, inclusive, for the texture object <T>. (q is defined in the Mipmapping discussion of section 3.8.8),

(*) For the purpose of this discussion, we consider it "possible" to sample from the texture object <T> bound to texture unit <U>" if any of the following are true:

- programmable vertex and fragment processing is disabled and the target of texture object <T> is enabled according to the texture target precedence rules of section 3.8.15, or
- if FRAGMENT_PROGRAM_ARB is enabled and the currently bound fragment program contains any instructions that sample from the texture object <T> bound to <U>, or
- if the active fragment or vertex shader contains any instructions that might sample from the texture object <T> bound to <U> if even those instructions might only be executed conditionally.

Note that if TEXTURE_BASE_LEVEL and TEXTURE_MAX_LEVEL exclude any levels containing image(s) attached to the currently bound framebuffer, then the above conditions will not be met, (i.e., the above rule will not cause the values of rendered fragments to be undefined.)

4.4.4 Framebuffer Completeness

A framebuffer object is said to be "framebuffer complete" if all of its attached images, and all framebuffer parameters required to utilize the framebuffer for rendering and reading, are consistently defined and meet the requirements defined below. The rules of framebuffer completeness are dependent on the properties of the attached images, and on certain implementation dependent restrictions. A framebuffer must be complete to effectively be used as the destination for GL framebuffer rendering operations and the source for GL framebuffer read operations.

The internal formats of the attached images can affect the completeness of the framebuffer, so it is useful to first define the relationship between the internal format of an image and the attachment points to which it can be attached.

* The following base internal formats from table 3.15 are "color-renderable": RGB, RGBA, FLOAT_R_NV, FLOAT_RG_NV, FLOAT_RGB_NV, and FLOAT_RGBA_NV. The sized internal formats from table 3.16 that have a color-renderable base internal format are also color-renderable. No other formats, including compressed internal formats, are color-renderable.

* An internal format is "depth-renderable" if it is DEPTH_COMPONENT, or if it is one of the sized internal formats from table 3.16 that has a depth-renderable base internal format. No other formats are depth-renderable.

* An internal format is "stencil-renderable" if it is STENCIL_INDEX, or if it is one of the sized internal formats from table 2.nnn that has a stencil-renderable base internal format. No other formats are stencil-renderable.

4.4.4.1 Framebuffer Attachment Completeness

If the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT for the framebuffer attachment point <attachment> is not NONE, then it is said that a framebuffer-attachable image, named <image>, is attached to the framebuffer at the attachment point. <image> is identified by the state in <attachment> as described in section 4.4.2.

The framebuffer attachment point <attachment> is said to be "framebuffer attachment complete" if the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT for <attachment> is NONE (i.e., no image is attached), or if all of the following conditions are true:

* <image> is a component of an existing object with the name specified by FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT, and of the type specified by FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT.

* The width and height of <image> must be non-zero.

* If FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT is TEXTURE and FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT names a 3-dimensional texture, then FRAMEBUFFER_ATTACHMENT_TEXTURE_ZOFFSET_EXT must be smaller than the depth of the texture.

* If <attachment> is one of COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT, then <image> must have a color-renderable internal format.

* If <attachment> is DEPTH_ATTACHMENT_EXT, then <image> must have a depth-renderable internal format.

* If <attachment> is STENCIL_ATTACHMENT_EXT, then <image> must have a stencil-renderable internal format.

4.4.4.2 Framebuffer Completeness

In this subsection, each rule is followed by an error enum enclosed in { brackets }. Sections 4.4.4.2 and 4.4.4.3 explains the relevance of the error enums.

The framebuffer object <target> is said to be "framebuffer complete" if it is the window-system-provided framebuffer, or if all the following conditons are true:

* All framebuffer attachment points are "framebuffer attachment complete".
  { FRAMEBUFFER_INCOMPLETE_ATTACHMENT_EXT }

* There is at least one image attached to the framebuffer.
  { FRAMEBUFFER_INCOMPLETE_MISSING_ATTACHMENT_EXT }

* All attached images have the same width and height.
  { FRAMEBUFFER_INCOMPLETE_DIMENSIONS_EXT }

* All images attached to the attachment points COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT must have the same internal format.
  { FRAMEBUFFER_INCOMPLETE_FORMATS_EXT }

* The value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT must not be NONE for any color attachment point(s) named by DRAW_BUFFERi.
  { FRAMEBUFFER_INCOMPLETE_DRAW_BUFFER_EXT }

* If READ_BUFFER is not NONE, then the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT must not be NONE for the color attachment point named by READ_BUFFER.
  { FRAMEBUFFER_INCOMPLETE_READ_BUFFER_EXT }

* The combination of internal formats of the attached images does not violate an implementation-dependent set of restrictions.
  { FRAMEBUFFER_UNSUPPORTED_EXT }

The enum in { brackets } after each clause of the framebuffer completeness rules specifies the return value of CheckFramebufferStatusEXT (see below) that is generated when that clause is violated. If more than one clause is violated, it is implementation-dependent exactly which enum will be returned by CheckFramebufferStatusEXT.

Performing any of the following actions may change whether the framebuffer is considered complete or incomplete.

- Binding to a different framebuffer with BindFramebufferEXT.

- Attaching an image to the framebuffer with FramebufferTexture{1D|2D|3D}EXT or FramebufferRenderbufferEXT.

- Detaching an image from the framebuffer with FramebufferTexture{1D|2D|3D}EXT or FramebufferRenderbufferEXT.

- Changing the width, height, or internal format of a texture image that is attached to the framebuffer by calling {Copy|Compressed}TexImage{1D|2D|3D}.

- Changing the width, height, or internal format of a renderbuffer that is attached to the framebuffer by calling RenderbufferStorageEXT.

- Deleting, with DeleteTextures or DeleteRenderbuffers, an object containing an image that is attached to a framebuffer object that is bound to the framebuffer.

- Changing READ_BUFFER or one of the DRAW_BUFFERS.

Although GL defines a wide variety of internal formats for framebuffer-attachable images, such as texture images and renderbuffer images, some implementations may not support rendering to particular combinations of internal formats. If the combination of formats of the images attached to a framebuffer object are not supported by the implementation, then the framebuffer is not complete under the clause labeled FRAMEBUFFER_UNSUPPORTED_EXT. There must exist, however, at least one combination of internal formats for which the framebuffer cannot be FRAMEBUFFER_UNSUPPORTED_EXT.

Because of the "implementation-dependent" clause of the framebuffer completeness test in particular, and because framebuffer completeness can change when the set of attached images is modified, it is strongly advised, though is not required, that an application check to see if the framebuffer is complete prior to rendering. The status of the framebuffer object currently bound to <target> can be queried by calling

```
    enum CheckFramebufferStatusEXT(enum target);
```

If <target> is not FRAMEBUFFER_EXT, INVALID_ENUM is generated. If CheckFramebufferStatusEXT is called within a Begin/End pair, INVALID_OPERATION is generated. If CheckFramebufferStatusEXT generates an error, 0 is returned.

Otherwise, an enum is returned that identifies whether or not the framebuffer bound to <target> is complete, and if not complete the enum identifies one of the rules of framebuffer completeness that is violated. If the framebuffer is complete, then FRAMEBUFFER_COMPLETE_EXT is returned.

4.4.4.3 Effects of Framebuffer Completeness on Framebuffer Operations

If the currently bound framebuffer is not framebuffer complete, then it is an error to attempt to use the framebuffer for writing or reading. This means that rendering commands such as Begin, RasterPos, any command that performs an implicit Begin, as well as commands that read the framebuffer such as ReadPixels and CopyTex{Sub}Image will generate the error INVALID_FRAMEBUFFER_OPERATION_EXT if called while the framebuffer is not framebuffer complete.

4.4.5 Effects of Framebuffer State on Framebuffer Dependent Values

The values of the state variables listed in table 9.nnn (Framebuffer Dependent Values) may change when a change is made to FRAMEBUFFER_BINDING_EXT, to the state of the currently bound framebuffer object, or to an image attached to the currently bound framebuffer object.

When FRAMEBUFFER_BINDING_EXT is zero, the values of the state variables listed in table 9.nnn are implementation defined.

When FRAMEBUFFER_BINDING_EXT is non-zero, if the currently bound framebuffer object is not framebuffer complete, then the values of the state variables listed in table 9.nnn are undefined.

When FRAMEBUFFER_BINDING_EXT is non-zero and the currently bound framebuffer object is framebuffer complete, then the values of the state variables listed in table 9.nnn are completely determined by FRAMEBUFFER_BINDING_EXT, the state of the currently bound framebuffer object, and the state of the images attached to the currently bound framebuffer object.

XXX [from jon leech] describe derivation of red green and blue size

4.4.6 Mapping between Pixel and Element in Attached Image

When FRAMEBUFFER_BINDING_EXT is non-zero, an operation that writes to the framebuffer modifies the image attached to the selected logical buffer, and an operation that reads from the framebuffer reads from the image attached to the selected logical buffer.

If the attached image is a renderbuffer image, then the window coordinates (x[w], y[w]) corresponds to the value in the renderbuffer image at the same coordinates.

If the attached image is a texture image, then the window coordinates (x[w], y[w]) correspond to the texel (i, j, k), from figure 3.10, as follows:

$$i = (x[w] - b)$$

$$j = (y[w] - b)$$

$$k = (zoffset - b)$$

where b is the texture image's border width, and zoffset is the value of FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET for the selected logical buffer. For a two-dimensional texture, k and zoffset are irrelevant; for a one-dimensional texture, j, k, and zoffset are both irrelevant.

(x[w], y[w]) corresponds to a border texel if x[w] or y[w] or zoffset is less than the border size, or if x[w] or y[w] or zoffset is greater than the border size plus the width or height or depth, resp., of the texture image.

Conversion to Framebuffer-Attachable Image Components

When an enabled color value is written to the framebuffer while FRAMEBUFFER_BINDING is non-zero, for each draw buffer the R, G, B, and A values are converted to internal components as described in table 3.15, according to the table row corresponding to the internal format of the framebuffer-attachable image attached to the selected logical buffer, and the resulting internal components are written to the image attached to logical buffer. The masking operations described in section 4.2.2 are also effective.

Conversion to RGBA Values

When a color value is read or is used as the source of a logical operation or blending, while FRAMEBUFFER_BINDING is non-zero, the components of the framebuffer-attachable image that is attached to the logical buffer selected by READ_BUFFER are first converted to R, G, B, and A values according to table 3.21 and the internal format of the attached image."

Additions to Chapter 5 of the OpenGL 1.5 Specification (Special Functions)

Added to section 5.4, as part of the discussion of which commands are not compiled into display lists:

"Certain commands, when called while compiling a display list, are not compiled into the display list but are executed immediately. These are: ..., GenFramebuffersEXT, BindFramebufferEXT, DeleteFramebuffersEXT, CheckFramebufferStatusEXT, GenRenderbuffersEXT, BindRenderbufferEXT, DeleteRenderbuffersEXT, RenderbufferStorageEXT, FramebufferTexture1DEXT, FramebufferTexture2DEXT, FramebufferTexture3DEXT, FramebufferRenderbufferEXT, GenerateMipmapEXT..."

Additions to Chapter 6 of the OpenGL 1.5 Specification (State and State Requests)

Add to section 6.1.3, Enumerated Queries:

In the list of state query functions, add:

```
"void GetFramebufferAttachmentParameterivEXT(enum target,
                                             enum attachment,
                                             enum pname,
                                             int *params);
```

<target> must be FRAMEBUFFER_EXT. <attachment> must be one of the attachment points of the framebuffer listed in table 1.nnn. <pname> must be one of the following: FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT, FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT, FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT, FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE_EXT, FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET_EXT.

If the framebuffer currently bound to <target> is zero, then INVALID_OPERATION is generated.

Upon successful return from GetFramebufferAttachmentParameterivEXT, if <pname> is FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT, then param will contain one of NONE, TEXTURE, or RENDERBUFFER_EXT, identifying the type of object which contains the attached image.

If the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT is RENDERBUFFER_EXT, then

If <pname> is FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT, <params> will contain the name of the renderbuffer object which contains the attached image.

Otherwise, INVALID_ENUM is generated.

```
        If the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT is
        TEXTURE, then

            If <pname> is FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT,
            then <params> will contain the name of the texture
            object which contains the attached image.

            If <pname> is FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT,
            then <params> will contain the mipmap level of the
            texture object which contains the attached image.

            If <pname> is
            FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE_EXT and the
            texture object named
            FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT is a cube map
            texture, then <params> will contain the cube map face of
            the cubemap texture object which contains the attached
            image.  Otherwise <params> will contain the value zero.

            If <pname> is
            FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET_EXT and the
            texture object named
            FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT is a
            3-dimensional texture, then <params> will contain the
            zoffset of the 2D image of the 3D texture object which
            contains the attached image.  Otherwise <params> will
            contain the value zero.

            Otherwise, INVALID_ENUM is generated.

    void GetRenderbufferParameterivEXT(enum target, enum pname,
                                       int* params);

        <target> must be RENDERBUFFER_EXT.  <pname> must be one of
        the symbolic values in table 8.nnn.

        If the renderbuffer currently bound to <target> is zero,
        then INVALID_OPERATION is generated.

        Upon successful return from GetRenderbufferParameterivEXT,
        if <pname> is RENDERBUFFER_WIDTH_EXT,
        RENDERBUFFER_HEIGHT_EXT, or
        RENDERBUFFER_INTERNAL_FORMAT_EXT, then <params> will contain
        the width in pixels, height in pixels, or internal format,
        respectively, of the image of the renderbuffer currently
        bound to <target>.

        Upon successful return from GetRenderbufferParameterivEXT,
        if <pname> is RENDERBUFFER_RED_SIZE_EXT,
        RENDERBUFFER_GREEN_SIZE_EXT, RENDERBUFFER_BLUE_SIZE_EXT,
        RENDERBUFFER_ALPHA_SIZE_EXT, RENDERBUFFER_DEPTH_SIZE_EXT, or
        RENDERBUFFER_STENCIL_SIZE_EXT, then <params> will contain
        the actual resolutions, (not the resolutions specified when
        the image array was defined), for the red, green, blue,
        alpha depth, or stencil components, respectively, of the
        image of the renderbuffer currently bound to <target>.
```

Otherwise, INVALID_ENUM is generated."

After section 6.1.13 and before section 6.1.14 (which should be renumbered 6.1.16), add two new sections:

6.1.14 Framebuffer Object Queries

The command

```
boolean IsFramebufferEXT( uint framebuffer );
```

returns TRUE if <framebuffer> is the name of an framebuffer object. If <framebuffer> is zero, or if <framebuffer> is a non-zero value that is not the name of an framebuffer object, IsFramebufferEXT return FALSE.

6.1.15 Renderbuffer Object Queries

The command

```
boolean IsRenderbufferEXT( uint renderbuffer );
```

returns TRUE if <renderbuffer> is the name of a renderbuffer object. If <renderbuffer> is zero, or if <renderbuffer> is a non-zero value that is not the name of a renderbuffer object, IsRenderbufferEXT return FALSE.

Errors

The error INVALID_OPERATION is generated if FRAMEBUFFER_BINDING_EXT is zero and DrawBuffer or DrawBuffers is called with a <buf> constant (other than NONE) that does not correspond to a buffer allocated to the GL by the window-system, including the constants COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT, where n is MAX_COLOR_ATTACHMENTS_EXT - 1.

The error INVALID_OPERATION is generated if FRAMEBUFFER_BINDING_EXT is non-zero and DrawBuffer, DrawBuffers, or ReadBuffer is called with a <buf> constant (other than NONE) that is not in the range COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT, where n is MAX_COLOR_ATTACHMENTS_EXT - 1.

The error INVALID_ENUM is generated if DrawBuffer or ReadBuffer is called with a <buf> constant that is not listed in table 4.4 or 10.nnn.

The error INVALID_ENUM is generated if DrawBuffers is called with a <buf> constant that is not listed in table 10.nnn or 11.nnn.

The error INVALID_FRAMEBUFFER_OPERATION_EXT is generated if the value of FRAMEBUFFER_STATUS_EXT is not FRAMEBUFFER_COMPLETE_EXT when any attempts to render to or read from the framebuffer are made.

The error INVALID_OPERATION is generated if GetFramebufferAttachmentParameterivEXT is called while the value of FRAMEBUFFER_BINDING_EXT is zero.

```
    The error INVALID_OPERATION is generated if
    FramebufferRenderbufferEXT or FramebufferTexture{1D|2D|3D}EXT is
    called  while the value of FRAMEBUFFER_BINDING_EXT is zero.

    The error INVALID_OPERATION is generated if RenderbufferStorageEXT
    or GetRenderbufferParameterivEXT is called while the value of
    RENDERBUFFER_BINDING_EXT is zero.

    The error INVALID_ENUM is generated if
    GetFramebufferAttachmentParameterivEXT is called with an
    <attachment> other than COLOR_ATTACHMENT0_EXT through
    COLOR_ATTACHMENTn_EXT, where n is MAX_COLOR_ATTACHMENTS_EXT - 1.

    The error INVALID_ENUM is generated if
    GetFramebufferAttachmentParameterivEXT is called with a <pname>
    other than FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT when the type of
    the attached object at the named attachment point is
    RENDERBUFFER_EXT.

    The error INVALID_ENUM is generated if
    GetFramebufferAttachmentParameterivEXT is called with a <pname>
    other than FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT,
    FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT,
    FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE_EXT, or
    FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET_EXT when the type of the
    attached object at the named attachment point is TEXTURE.

    The error INVALID_ENUM is generated if GetRenderbufferParameterivEXT
    is called with a <pname> other than RENDERBUFFER_WIDTH_EXT,
    RENDERBUFFER_HEIGHT_EXT, or RENDERBUFFER_INTERNAL_FORMAT_EXT,
    GL_RENDERBUFFER_RED_SIZE, GL_RENDERBUFFER_GREEN_SIZE,
    GL_RENDERBUFFER_BLUE_SIZE, GL_RENDERBUFFER_ALPHA_SIZE,
    GL_RENDERBUFFER_DEPTH_SIZE, or GL_RENDERBUFFER_STENCIL_SIZE.

    The error INVALID_VALUE is generated if RenderbufferStorageEXT is
    called with a <width> or <height> that is greater than
    MAX_RENDERBUFFER_SIZE_EXT.

    The error INVALID_ENUM is generated if RenderbufferStorageEXT is
    called with an <internalformat> that is not RGB, RGBA,
    DEPTH_COMPONENT, STENCIL_INDEX, or one of the internal formats from
    table 3.16 or table 2.nnn that has a base internal format of RGB,
    RGBA, DEPTH_COMPONENT, or STENCIL_INDEX.

    The error INVALID_OPERATION is generated if
    FramebufferRenderbufferEXT is called and <renderbuffer> is not the
    name of a renderbuffer object.

    The error INVALID_OPERATION is generated if
    FramebufferTexture{1D|2D|3D}EXT is called and <texture> is not the
    name of a texture object.

    The error INVALID_VALUE is generated if
    FramebufferTexture{1D|2D|3D}EXT is called with a <level> that is
    less than zero.
```

The error INVALID_VALUE is generated if FramebufferTexture2DEXT is called with a <level> that is not zero and <textarget> is TEXTURE_RECTANGLE_ARB.

The error INVALID_VALUE is generated if FramebufferTexture{1D|2D}EXT is called with a <level> that is greater than the log base 2 of MAX_TEXTURE_SIZE and <texture> is a 1D or 2D texture.

The error INVALID_VALUE is generated if FramebufferTexture2DEXT is called with a <level> that is greater than the log base 2 of MAX_CUBE_MAP_TEXTURE_SIZE and <texture> is a cubemap texture.

The error INVALID_VALUE is generated if FramebufferTexture3DEXT is called with a <level> greater than the log base 2 of the MAX_3D_TEXTURE_SIZE.

The error INVALID_VALUE is generated if FramebufferTexture3DEXT is called with a <zoffset> that is larger than MAX_3D_TEXTURE_SIZE-1.

The error INVALID_ENUM is generated if CheckFramebufferStatusEXT is called and <target> is not FRAMEBUFFER_EXT.

The error INVALID_OPERATION is generated if CheckFramebufferStatusEXT is called within a Begin/End pair.

The error OUT_OF_MEMORY is generated if the GL is unable to create a data store of the required size when calling RenderbufferStorageEXT.

The error INVALID_OPERATION is generated if GenerateMipmapEXT is called with a <target> of TEXTURE_CUBE_MAP and the texture object currently bound to TEXTURE_CUBE_MAP is not "cube complete" as defined in section 3.8.10

New State

(add new table 3.nnn, "Framebuffer (state per framebuffer target binding point)")

Get Value	Type	Get Command	Initial Value	Description	Section	Attribute
FRAMEBUFFER_BINDING_EXT	Z	GetIntegerv	0	name of framebuffer object bound to FRAMEBUFFER_EXT target	4.4.1	-

(insert new table 4.nnn, "Framebuffer (state per framebuffer object)")

Get Value	Type	Get Command	Initial Value	Description	Section	Attribute
DRAW_BUFFERi [1]	1 + xZ(10*)	GetIntegerv	see 4.2.1	draw buffer selected for color output i	4.2.1	color-buffer
READ_BUFFER [2]	Z(3)	GetIntegerv	see 4.3.2	read source	4.3.2	pixel

[1] prior to this extension, the DRAW_BUFFERi state was described in table 6.21 "Framebuffer Control" (of OpenGL 2.0 spec)
[2] prior to this extension, the READ_BUFFER state was described in table 6.26 "Pixel" (of OpenGL 2.0 spec)

(insert new table 5.nnn, "Framebuffer (state per framebuffer object attachment point)")

Get Value	Type	Get Command	Initial Value	Description	Section	Attribute
FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT	Z	GetFramebufferAttachmentParameterivEXT	NONE	type of image attached to framebuffer attachment point	4.4.2.2 and 4.4.2.3	-
FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT	Z	GetFramebufferAttachmentParameterivEXT	0	name of object attached to framebuffer attachment point	4.4.2.2 and 4.4.2.3	-
FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT	Z	GetFramebufferAttachmentParameterivEXT	0	mipmap level of texture image attached, if object attached is texture.	4.4.2.2 and 4.4.2.3	-
FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE_EXT	Z+	GetFramebufferAttachmentParameterivEXT	TEXTURE_ CUBE_MAP_ POSITIVE_X	cubemap face of texture image attached, if object attached is cubemap texture.	4.4.2.2 and 4.4.2.3	-
FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET_EXT	Z	GetFramebufferAttachmentParameterivEXT	0	zoffset of texture image attached, if object attached is 3D texture.	4.4.2.2 and 4.4.2.3	-

(insert new table 7.nnn, "Renderbuffers (state per renderbuffer target and binding point)")

Get Value	Type	Get Command	Initial Value	Description	Section	Attribute
RENDERBUFFER_BINDING_EXT	Z	GetIntegerv	0	renderbuffer object bound to RENDERBUFFER_EXT	4.4.2.1	-

(insert new table 8.nnn, "Renderbuffers (state per renderbuffer object)")

Get Value	Type	Get Command	Initial Value	Description	Section	Attribute
RENDERBUFFER_WIDTH_EXT	Z	GetRenderbufferParameterivEXT	0	width of renderbuffer	4.4.2.1	-
RENDERBUFFER_HEIGHT_EXT	Z	GetRenderbufferParameterivEXT	0	height of renderbuffer	4.4.2.1	-
RENDERBUFFER_INTERNAL_FORMAT_EXT	Z+	GetRenderbufferParameterivEXT	RGBA	internal format of renderbuffer	4.4.2.1	-
RENDERBUFFER_RED_SIZE_EXT	Z	GetRenderbufferParameterivEXT	0	size in bits of renderbuffer image's red component	4.4.2.1	-
RENDERBUFFER_GREEN_SIZE_EXT	Z	GetRenderbufferParameterivEXT	0	size in bits of renderbuffer image's green component	4.4.2.1	-
RENDERBUFFER_BLUE_SIZE_EXT	Z	GetRenderbufferParameterivEXT	0	size in bits of renderbuffer image's blue component	4.4.2.1	-
RENDERBUFFER_ALPHA_SIZE_EXT	Z	GetRenderbufferParameterivEXT	0	size in bits of renderbuffer image's alpha component	4.4.2.1	-
RENDERBUFFER_DEPTH_SIZE_EXT	Z	GetRenderbufferParameterivEXT	0	size in bits of renderbuffer image's depth component	4.4.2.1	-
RENDERBUFFER_STENCIL_SIZE_EXT	Z	GetRenderbufferParameterivEXT	0	size in bits of renderbuffer image's stencil component	4.4.2.1	-

Move the following existing state from "Implementation Dependent Values", tables 6.31-6.36 to into a new table called "Framebuffer Dependent Values", table 9.nnn.

```
    Get Value
    ---------
    AUX_BUFFERS
    MAX_DRAW_BUFFERS
    RGBA_MODE
    INDEX_MODE
    DOUBLEBUFFER
    STEREO
    SAMPLE_BUFFERS
    SAMPLES
    RED_BITS
    GREEN_BITS
    BLUE_BITS
    ALPHA_BITS
    DEPTH_BITS
    STENCIL_BITS
    ACCUM_RED_BITS
    ACCUM_GREEN_BITS
    ACCUM_BLUE_BITS
    ACCUM_ALPHA_BITS
    STENCIL_REF
```

To the same table called "Framebuffer Dependent Values", table 9.nnn add the following new framebuffer dependent state.

Get Value	Type	Get Command	Minimum Value	Description	Section	Attribute
MAX_COLOR_ATTACHMENTS_EXT	Z+	GetIntegerv	1	Maximum number of attachment points for color buffers when using framebuffer objects	4.4.2.2	-

New Implementation Dependent State

Get Value	Type	Get Command	Minimum Value	Description	Section	Attribute
MAX_RENDERBUFFER_SIZE_EXT	Z+	GetIntegerv	1	Maximum width and height of renderbuffers supported by the implementation	4.4.2.1	-

Additions to the AGL/GLX/WGL Specifications and dependencies on WGL_ARB_make_current_read, GLX_SGI_make_current_read, and GLX 1.3

The color, depth, stencil, aux, and accum logical buffers defined by the <draw> and <read> drawables passed to glXMakeContextCurrent, glXMakeCurrent, and glXMakeCurrentRead are ignored while the value of FRAMEBUFFER_BINDING_EXT is non-zero.

Dependencies on ATI_draw_buffers and ARB_draw_buffers

If neither ATI_draw_buffers nor ARB_draw_buffers are supported, then all discussions of DrawBuffers should be ignored.

```
    In addition, the language describing DrawBuffers are derived from a
    combination of the ARB_draw_buffers specification and section 4.2.1
    of the OpenGL 2.0 specification.
```

Dependencies on ARB_fragment_program, ARB_fragment_shader, and ARB_vertex_shader

```
    If ARB_fragment_program, ARB_fragment_shader, and ARB_vertex_shader
    are all not supported, then all references to the currently bound
    program or shader should be ignored.
```

Dependencies on ARB_texture_rectangle

```
    If ARB_texture_rectangle is not supported, then all references to
    TEXTURE_RECTANGLE_ARB should be ignored.
```

Dependencies on EXT_packed_depth_stencil

```
    If EXT_packed_depth_stencil is not supported, then all references to
    DEPTH_STENCIL internal formats should be ignored.
```

Dependencies on NV_float_buffer

```
    If NV_float_buffer is not supported, then all references to the
    following internal formats should be ignored: FLOAT_R_NV,
    FLOAT_RG_NV, FLOAT_RGB_NV, and FLOAT_RGBA_NV.
```

Dependencies on NV_texture_shader

```
    The following base internal formats are not color-renderable,
    depth-renderable, or stencil-renderable: HILO_NV, DSDT_NV,
    DSDT_MAG_NV, and DSDT_MAG_INTENSITY_NV.
```

GLX Protocol

```
        Seventeen new GL commands are added.

        The following ten rendering commands are sent to the sever as part
        of a glXRender request:
```

BindRenderbufferEXT

```
            2        12               rendering command length
            2        4316             rendering command opcode
            4        ENUM             target
            4        CARD32           renderbuffer
```

DeleteRenderbufferEXT

```
            2        8+n*4            rendering command length
            2        4317             rendering command opcode
            4        CARD32           n
            n*4      LISTofCARD32     renderbuffers
```

RenderbufferStorageEXT

2	20	rendering command length
2	4318	rendering command opcode
4	ENUM	target
4	ENUM	internalFormat
4	CARD32	width
4	CARD32	height

BindFramebufferEXT

2	12	rendering command length
2	4319	rendering command opcode
4	ENUM	target
4	CARD32	framebuffer

DeleteFramebufferEXT

2	8+n*4	rendering command length
2	4320	rendering command opcode
4	CARD32	n
n*4	LISTofCARD32	framebuffers

FramebufferTexture1DEXT

2	24	rendering command length
2	4321	rendering command opcode
4	ENUM	target
4	ENUM	attachement
4	ENUM	textarget
4	CARD32	texture
4	CARD32	level

FramebufferTexture2DEXT

2	24	rendering command length
2	4322	rendering command opcode
4	ENUM	target
4	ENUM	attachement
4	ENUM	textarget
4	CARD32	texture
4	CARD32	level

FramebufferTexture3DEXT

2	28	rendering command length
2	4323	rendering command opcode
4	ENUM	target
4	ENUM	attachement
4	ENUM	textarget
4	CARD32	texture
4	CARD32	level
4	CARD32	zoffset

FramebufferRenderbufferEXT

2	20	rendering command length
2	4324	rendering command opcode
4	ENUM	target
4	ENUM	attachment
4	ENUM	renderbuffertarget
4	CARD32	renderbuffer

```
GenerateMipmapEXT
    2        8                rendering command length
    2        4325             rendering command opcode
    4        ENUM             target

The remaining seven commands are non-rendering commands.  These
commands are sent separately (i.e., not as part of a glXRender or
glXRenderLarge request), using the glXVendorPrivateWithReply
request:

IsRenderbufferEXT
    1        CARD8            opcode (X assigned)
    1        17               GLX opcode (X_GLXVendorPrivateWithReply)
    2        4                request length
    4        1422             vendor specific opcode
    4        GLX_CONTEXT_TAG  context tag
    4        CARD32           renderbuffer
  =>
    1        1                reply
    1                         unused
    2        CARD16           sequence number
    4        0                reply length
    4        BOOL32           return value
    20                        unused

GenRenderbuffersEXT
    1        CARD8            opcode (X assigned)
    1        17               GLX opcode (X_GLXVendorPrivateWithReply)
    2        4                request length
    4        1423             vendor specific opcode
    4        GLX_CONTEXT_TAG  context tag
    4        CARD32           n
  =>
    1        1                reply

            n*4      LISTofCARD32    params
```

Usage Examples

The following examples use a helper macro for CHECK_FRAMEBUFFER_STATUS, defined below.

Example (6) gives a (very slightly) more robust example of handling the possible return values for glCheckFramebufferStatusEXT.

```
#define CHECK_FRAMEBUFFER_STATUS()                            \
  {                                                           \
    GLenum status;                                            \
    status = glCheckFramebufferStatusEXT(GL_FRAMEBUFFER_EXT); \
    switch(status) {                                          \
      case GL_FRAMEBUFFER_COMPLETE_EXT:                       \
        break;                                                \
      case GL_FRAMEBUFFER_UNSUPPORTED_EXT:                    \
        /* choose different formats */                        \
        break;                                                \
      default:                                                \
        /* programming error; will fail on all hardware */    \
        assert(0);                                            \
    }
  }
```

(1) Render to 2D texture with a depth buffer

```
    // Given:  color_tex - TEXTURE_2D color texture object
    //         depth_rb  - GL_DEPTH renderbuffer object
    //         fb        - framebuffer object

    // Enable render-to-texture
    glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb);

    // Set up color_tex and depth_rb for render-to-texture
    glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                              GL_COLOR_ATTACHMENT0_EXT,
                              GL_TEXTURE_2D, color_tex, 0);
    glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,
                                 GL_DEPTH_ATTACHMENT_EXT,
                                 GL_RENDERBUFFER_EXT, depth_rb);

    // Check framebuffer completeness at the end of initialization.
    CHECK_FRAMEBUFFER_STATUS();

    <draw to the texture and renderbuffer>

    // Re-enable rendering to the window
    glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, 0);

    glBindTexture(GL_TEXTURE_2D, color_tex);
    <draw to the window, reading from the color_tex>
```

(2) Application that supports both RBBCTT (render back buffer, copy to texture) and RTT (render to texture). The migration path from RBBCTT to RTT is easy.

```
    if (useFramebuffer) {
        glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb);
        glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                                  GL_COLOR_ATTACHMENT0_EXT,
                                  GL_TEXTURE_2D, color_tex, 0);
        CHECK_FRAMEBUFFER_STATUS();
    }

    draw_to_texture();

    glBindTexture (GL_TEXTURE_2D, color_tex);
    if (useFramebuffer) {
        glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, 0);
    } else { // copy tex path
        glCopyTexSubImage(...);
    }
```

(3) Simple render-to-texture loop with initialization. Create an RGB8 texture, a 24-bit depth renderbuffer, and a stencil renderbuffer. In a loop, alternate between rendering to, and texturing out of, the color texture.

```
    glGenFramebuffersEXT(1, &fb);
    glGenTextures(1, &color_tex);
    glGenRenderbuffersEXT(1, &depth_rb);
    glGenRenderbuffersEXT(1, &stencil_rb);

    glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb);

    // initialize color texture
    glBindTexture(GL_TEXTURE_2D, color_tex);
    glTexParameterf(GL_TEXTURE_2D, GL_TEXTURE_MIN_FILTER, GL_LINEAR);
    glTexImage2D(GL_TEXTURE_2D, 0, GL_RGB8, 512, 512, 0,
                 GL_RGB, GL_INT, NULL);
    glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                              GL_COLOR_ATTACHMENT0_EXT,
                              GL_TEXTURE_2D, color_tex, 0);

    // initialize depth renderbuffer
    glBindRenderbufferEXT(GL_RENDERBUFFER_EXT, depth_rb);
    glRenderbufferStorageEXT(GL_RENDERBUFFER_EXT,
                             GL_DEPTH_COMPONENT24, 512, 512);
    glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,
                                 GL_DEPTH_ATTACHMENT_EXT,
                                 GL_RENDERBUFFER_EXT, depth_rb);

    // initialize stencil renderbuffer
    glBindRenderbufferEXT(GL_RENDERBUFFER_EXT, stencil_rb);
    glRenderbufferStorageEXT(GL_RENDERBUFFER_EXT,
                             GL_STENCIL_INDEX, 512, 512);
    glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,
                                 GL_STENCIL_ATTACHMENT_EXT,
                                 GL_RENDERBUFFER_EXT, stencil_rb);

    // Check framebuffer completeness at the end of initialization.
    CHECK_FRAMEBUFFER_STATUS();

    loop {
        glBindTexture(GL_TEXTURE_2D, 0);
        glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb);

        <draw to the texture>

        glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, 0);
        glBindTexture(GL_TEXTURE_2D, color_tex);

        <draw to the window, reading from the color texture>
    }
```

(4) Render-to-texture loop with automatic mipmap generation. There are N framebuffers, N mipmap color textures, and a single shared depth renderbuffer. The depth renderbuffer is not a mipmap.

```
GLuint fb_array[N];
GLuint color_tex_array[N];
GLuint depth_rb;

glGenFramebuffersEXT(N, fb_array);
glGenTextures(N, color_tex_array);
glGenRenderbuffersEXT(1, &depth_rb);

// initialize color textures
for (int i=0; i<N; i++) {
  glBindTexture(GL_TEXTURE_2D, color_tex_array[N]);
  glTexImage2D(GL_TEXTURE_2D, 0, GL_RGB8, 512, 512, 0,
               GL_RGB, GL_INT, NULL);

  // establish a mipmap chain for the texture
  glGenerateMipmapEXT(GL_TEXTURE_2D);
}

// initialize depth renderbuffer
glBindRenderbufferEXT(GL_RENDERBUFFER_EXT, depth_rb);
glRenderbufferStorageEXT(GL_RENDERBUFFER_EXT,
                         GL_DEPTH_COMPONENT24, 512, 512);

// setup framebuffers, sharing depth
for (int i=0; i<N; i++) {
  glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb_array[i]);
  glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                            GL_COLOR_ATTACHMENT0_EXT,
                            GL_TEXTURE_2D, color_tex_array[i], 0);
  glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,
                               GL_DEPTH_ATTACHMENT_EXT,
                               GL_RENDERBUFFER_EXT, depth_rb);
}

// Check framebuffer completeness at the end of initialization.
CHECK_FRAMEBUFFER_STATUS();
```

```
        loop {
            glBindTexture(GL_TEXTURE_2D, 0);

            for (int i=0; i<N; i++) {
              glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb_array[i]);
              <draw to texture i>
            }

            glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, 0);

            // automatically generate mipmaps
            for (int i=0; i<N; i++) {
              glBindTexture(GL_TEXTURE_2D, color_tex_array[i]);
              glGenerateMipmapEXT(GL_TEXTURE_2D);
            }

            <draw to the window, reading from the color textures>
        }
```

**(5) Render-to-texture loop with custom mipmap generation.
The depth renderbuffer is not a mipmap.**

```
        glGenFramebuffersEXT(1, &fb);
        glGenTextures(1, &color_tex);
        glGenRenderbuffersEXT(1, &depth_rb);

        glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb);

        // initialize color texture and establish mipmap chain
        glBindTexture(GL_TEXTURE_2D, color_tex);
        glTexImage2D(GL_TEXTURE_2D, 0, GL_RGB8, 512, 512, 0,
                     GL_RGB, GL_INT, NULL);
        glGenerateMipmapEXT(GL_TEXTURE_2D);
        glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                                  GL_COLOR_ATTACHMENT0_EXT,
                                  GL_TEXTURE_2D, color_tex, 0);

        // initialize depth renderbuffer
        glBindRenderbufferEXT(GL_RENDERBUFFER_EXT, depth_rb);
        glRenderbufferStorageEXT(GL_RENDERBUFFER_EXT,
                                 GL_DEPTH_COMPONENT24, 512, 512);
        glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,
                                     GL_DEPTH_ATTACHMENT_EXT,
                                     GL_RENDERBUFFER_EXT, depth_rb);

        // Check framebuffer completeness at the end of initialization.
        CHECK_FRAMEBUFFER_STATUS();
```

```
loop {
    glBindTexture(GL_TEXTURE_2D, 0);

    glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb);
    glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                              GL_COLOR_ATTACHMENT0_EXT,
                              GL_TEXTURE_2D, color_tex, 0);
    glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,
                                 GL_DEPTH_ATTACHMENT_EXT,
                                 GL_RENDERBUFFER_EXT, depth_rb);

    <draw to the base level of the color texture>

    // custom-generate successive mipmap levels
    glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,
                                 GL_DEPTH_ATTACHMENT_EXT,
                                 GL_RENDERBUFFER_EXT, 0);
    glBindTexture(GL_TEXTURE_2D, color_tex);
    foreach (level > 0, in order of increasing values of level) {
        glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                                  GL_COLOR_ATTACHMENT0_EXT,
                                  GL_TEXTURE_2D, color_tex, level);
        glTexParameteri(TEXTURE_2D, TEXTURE_BASE_LEVEL, level-1);
        glTexParameteri(TEXTURE_2D, TEXTURE_MAX_LEVEL, level-1);

        <draw to level>
    }
    glTexParameteri(TEXTURE_2D, TEXTURE_BASE_LEVEL, 0);
    glTexParameteri(TEXTURE_2D, TEXTURE_MAX_LEVEL, max);

    glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, 0);
    <draw to the window, reading from the color texture>
}
```

(6) Pseudo-code example of one method of responding to FRAMEBUFFER_UNSUPPORTED_EXT

```
        bool done = false;
        bool success = false;
        int  configurationNumber = 0;
        GLenum status;

        while (!done)
        {
            for (each framebuffer-attachable image)
            {

ChooseInternalFormatForFramebufferAttachableImage(configurationNumber);

                CreateFramebufferAttachableImage();

                AttachFramebufferAttachableImageToFramebuffer();
            }

            status = glCheckFramebufferStatusEXT(GL_FRAMEBUFFER_EXT);
            switch(status)
            {
                case GL_FRAMEBUFFER_COMPLETE_EXT:
                    success = true;
                    done = true;
                    break;

                case GL_FRAMEBUFFER_UNSUPPORTED_EXT:
                    if (configCount < MAX_NUM_CONFIGS_I_WANT_TO_TRY)
                    {
                        printf("current config not supported, trying again);
                        configurationNumber++;
                    }
                    else
                    {
                        printf("couldn't find a supported config\n");
                        success = false;
                        done = true;
                    }
                    break;

                default:
                    // programming error; will fail on all hardware
                    FatalError();
                    exit(1);
            }
        }
        if (!success)
        {
            printf("couldn't find a supported config\n");
            FatalError();
            exit(1);
        }

        // Current framebuffer is supported and complete!!
        Draw();
```

(7) Render to depth texture with no color attachments

```
        // Given:  depth_tex - TEXTURE_2D depth texture object
        //         fb        - framebuffer object

        // Enable render-to-texture
        glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb);

        // Set up depth_tex for render-to-texture
        glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                                  GL_DEPTH_ATTACHMENT_EXT,
                                  GL_TEXTURE_2D, depth_tex, 0);

        // No color buffer to draw to or read from
        glDrawBuffer(GL_NONE);
        glReadBuffer(GL_NONE);

        // Check framebuffer completeness at the end of initialization.
        CHECK_FRAMEBUFFER_STATUS();

        <draw something>

        // Re-enable rendering to the window
        glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, 0);

        glBindTexture(GL_TEXTURE_2D, depth_tex);
        <draw to the window, reading from the depth_tex>
```

(8) FBO and ARB_draw_buffers

```
    // Given: color_texA - TEXTURE_2D color texture object
    // Given: color_texB - TEXTURE_2D color texture object
    //        depth_rb   - GL_DEPTH renderbuffer object
    //        fb         - framebuffer object

    // Set up the framebuffer object
    glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, fb);
    glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                              GL_COLOR_ATTACHMENT0_EXT,
                              GL_TEXTURE_2D, color_texA, 0);
    glFramebufferTexture2DEXT(GL_FRAMEBUFFER_EXT,
                              GL_COLOR_ATTACHMENT1_EXT,
                              GL_TEXTURE_2D, color_texB, 0);
    glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,
                                 GL_DEPTH_ATTACHMENT_EXT,
                                 GL_RENDERBUFFER_EXT, depth_rb);

    // Enable both attachments as draw buffers
    GLenum drawbuffers = {GL_COLOR_ATTACHMENT0_EXT,
                          GL_COLOR_ATTACHMENT1_EXT};
    glDrawBuffers(2, drawbuffers);

    // Check framebuffer completeness at the end of initialization.
    CHECK_FRAMEBUFFER_STATUS();

    // Enable fragment program that writes to both gl_FragData[0]
    // and gl_FragData[1]

    <draw something>

    // Disable fragment program

    // Re-enable rendering to the window
    glBindFramebufferEXT(GL_FRAMEBUFFER_EXT, 0);

    // Bind both textures, each to a different texture unit
    glActiveTexture(GL_TEXTURE0);
    glBindTexture(GL_TEXTURE_2D, color_texA);
    glActiveTexture(GL_TEXTURE1);
    glBindTexture(GL_TEXTURE_2D, color_texB);

    <draw to the window>
```

Issues

```
    (1)  We obviously won't call this "ARB_compromise_buffers", so
         what name should we use?

            RESOLUTION: resolved, EXT_framebuffer_object

            Possibilities considered include:
                EXT_framebuffer
                EXT_framebuffer_object
                EXT_renderable_buffers
                EXT_renderbuffer
                EXT_superbuffers (hah!)
                EXT_renderable_image
                EXT_render_image

            The lead candidates were EXT_renderable_image and
            EXT_framebuffer_object Since this extension introduced both
            new concepts into OpenGL, this was a bit of a toss up.
            EXT_framebuffer_object was chosen based on a weak precedent
            given by EXT_texture_object and ARB_vertex_buffer_object

    (2)  Many developers complain about the OpenGL/glX/WGL/agl pbuffer
         API, which they use both to do "render to texture" and to do
         general offscreen (non-windowed) accelerated rendering.  This
         extension is intended to subsume, some and perhaps all of, the
         functionality currently handled by pbuffers.  Should this
         extension (initially?) support only render-to-texture or should
         it try to provide an OpenGL API to fully replace the pbuffer
         API?

            RESOLUTION:  This extension should fully replace the pbuffer API.

            The implication of this decision is that this API should provide
            a way to support rendering to offscreen buffers that are not
            textures.

    (3)  As a consequence of issue (2), this extension adds the concept of
         share-able, non-texturable renderable entitites that can be
         used as color buffers, depth buffers, stencil buffers, etc.
         The OpenGL spec refers to these entities as "logical buffers".
         What should this spec call them?

            RESOLUTION: "renderbuffer", (one word)

            We could just call them "logical buffers", but is there a
            better name?
```

```
        The group considered:
        logical buffer  - possible, kind of general
        render buffer   - clear, (one word or two?)
        renderable      - clear, but may conflict with glx "drawable"
        drawable        - confusing: glx "drawable" == gl "framebuffer"
        render surface  - possible
        render target   - possible
        image buffer    - may get confused with Tex"Image"
        image           - may get confused with Tex"Image"
        surface buffer  - too verbose?
        surface         - too general
        others???

        The group felt "render buffer " (or possibly "renderbuffer")
        provides for the clearest expression of the purpose for
        these buffers.

        We finally decided on "renderbuffer" because we didn't want
        to use "render" as an adjective to describe a generic
        buffer, but rather decided to coin a new compound word to
        describe this concept.
```

(4) How should the specification refer to the group of various types of objects that can be attached to the framebuffer attachment points?

```
        RESOLUTION:  The specification will use the phrase
        "framebuffer-attachable images" to mean the 2D array of
        pixels (image) of a "renderbuffer", a "texture", or any
        other items that could be attached to a framebuffer.

            Options considered include:
              "render target"
              "renderable image"
              "framebuffer-attachable

        Initially, we chose the phrase "render target" for this but
        felt it didn't accurately capture the concept of a 2D array
        of pixels that was simultaneously useable as the storage of
        a texture object and the destination of rendering.

        We then tried to borrow the "image" language of OpenGL which
        describes texture's pixel arrays as "images" and we chose
        the term "renderable image".

        However, in the end, we felt that the salient characteristic
        of these images was that we could attach them to a
        framebuffer and settled on the term "framebuffer-attachable
        image".
```

(5) *How should the specification refer to the places in a framebuffer that can hold a framebuffer-attachable image?*

RESOLUTION: This state is called an "attachment point" of the framebuffer.

"attachment points" will be be used to describe the framebuffer state that holds a connection to a given framebuffer-attachable image (a renderbuffer image or a texture image). The framebuffer attachment points include the framebuffer's color buffers, stencil buffer, depth buffer, and aux buffer.

The word "attach" is being used to refer to connecting one object to another. "bind" refers to connecting an object to the context state. A texture image can be attached to a framebuffer object, but a framebuffer object is bound into the context state vector.

(6) *This extension adds the concept of collections of "logical buffers", to replace the window-system provided collection (drawable, or window) of logical buffers. What should we call these?*

RESOLUTION: "framebuffer"

For the "collection of logical buffers" object, the group considered the names: "framebuffer", "renderTarget", "drawable". We chose "framebuffer" since this is consistent with how the OpenGL specification already uses the word framebuffer.

(7) *This extension introduces two new object types into the OpenGL: renderbuffer objects and framebuffer objects. For handling these objects, there are two main object manipulation methodology precedents to choose from:*

```
1) "texture/program/vbo" object model:
        app-supplied int handles,
        Gen/is/Bind/Delete functions

2) "GLSL" object model:
        driver-supplied GLhandle handles,
        Create/Delete/Attach, etc
```

Which methodology should this extension use for each new object?

RESOLUTION: Use Option (1), "texture" object methodology, for both "renderbuffer" objects and framebuffer objects.

This is consistent with the June, 2004 ARB meeting vote to use the "texture" object methodlogy as the default object methodology.

(8) Do we need separate framebuffer objects?

RESOLUTION: yes.

The framebuffer object is an object to encapsulate the state of the framebuffer and the collection of framebuffer-attachable images attached to the logical buffer attachment points. A question was raised early on about whether we should have separate, shareable framebuffer objects or we should fold a single framebuffer "object" state vector into the context.

We decided to leave framebuffer objects in the API, with the understanding that we could easily remove them from the API and the spec later if a convincing case was argued for removing it.

There are several reasons why framebuffer objects were introduced:

FB1. It can be "expensive" (for some definition of expensive) to validate the framebuffer and all its attached objects. There is a desire to be able to easily recognize that a particular state. combination has been seen and validated previously.

FB2. There is some subset of GL context state which only makes sense in its relationship to the current framebuffer and attached images (red bits, green bits, blue bits, etc, presence or absence of aux buffers or depth buffers, current value of draw buffer(s), read buffer, etc. etc). It would be nice if this state "tracked" changes to the current framebuffer configuration by being part of the framebuffer object state.

FB3. For a while, we considered adding "intrinsic" or "implicit" buffer storage to the framebuffer. This would be used for buffers that were either hidden from the user, like the multisample buffer, or perhaps needed to be explicitly formatted by the driver. If we did have this kind of "intrinsic" storage, then framebuffers would be a lot like textures and would have the same kinds of pressures to minimize vram, sharing storage across objects and contexts as textures did. In fact, they would be similar to cube map texture objects which had 6 attached face images, or mipmaped textures which had a set of mipmap level images. In the end we decided not to use intrinsic buffers, - see issue (13) - but we might decide to add them back in the future. For instance, one option for supporting multisampling is to use an implicit multisample buffer.

FB4. We realized that most of the "hard" issues introduced by this extension were completely orthogonal to the presence or absence of framebuffer objects. All of the same issues apply regardless of whether there is a single non-default framebuffer as part of the context or multiple framebuffer objects. These issues about attaching, (binding) objects, reformatting attached (or bound) images via TexImage/RenderbufferStorage, pixel format combinations, framebuffer completeness, and the relationship between a non-"default" framebuffer and the legacy window sytem framebuffer and pixel format all come in to play either way. So there is actually little implementation or conceptual cost incurred by the introduction of these framebuffer objects.

There were also a few reasons why we considered *not* adding framebuffer objects:

NoFB1. In the absence of "intrinsic" buffers, framebuffer objects only really consist of the attachment state. It is convenient to encapsulate this state into an object, but one could ask if it's any more convenient than say a "blend state" object or a "texture unit attachment state" object, which to date, we have chosen not to add into OpenGL.

NoFB2. As a "state-only" object, there's a question about how much state should be included - at least the attachment state should be included, but what about draw buffers state, what about the viewport state, what about other state? Since drawing the line is hard, we questioned whether we needed these objects.

NoFB3. Some amount of the functionality of the framebuffer objects could be implemented by the application with the appropriate use of display lists.

In weighing (FB1), expense of validating framebuffer state, versus (NoFB1), not wanting to introduce "state only" objects, we realized that framebuffer validation is more expensive than the blend state (for which there is no object in GL) and less expensive than a fragment program (for which there is an object in GL). While it's not exactly clear precisely where on the spectrum of "expense" the framebuffer validation lies, we decided that it may be expensive enough to justify creating a new object type. So we retained framebuffer objects in the API now, with the understanding that if we change our minds it's easier to rip them out later than it is to add them back in later.

(9) Should the routine which allocates a renderbuffer accept an image to initialize the buffer, analogous to how TexImage works?

RESOLUTION: no, it should allocate uninitialized storage

We could have allowed a renderbuffer "image" specification routine, but this would essentially serve the same purpose as a combined "allocate renderbuffer followed by DrawPixels" routine so we decided it was extraneous. The primary purpose of these buffers is to store rendered output anyway, so there was not sufficient demand to support an optimized path for data initialization. See related issue (10).

(10) What should we call the routine that allocates storage for the renderbuffer? This routine would be the moral equivalent of glTexImage.

RESOLUTION: RenderbufferStorage()

```
Options included:
    RenderbufferStorage()
    RenderbufferImage()
    others???
```

This is really a function of how we resolve issue (9).

RenderbufferImage would be appropriate if the allocation routine could take an image to initialize the renderbuffer.

RenderbufferStorage would be more appropriate if the allocation routine does not take an image.

Since the group decided supporting an "initialization" image for a "renderbuffer" was too much overlapping functionality with DrawPixels, RenderbufferStorage was chosen.

(11) The routine(s) which attach a texture to a framebuffer attachment point need to describe which image in the texture they are using, i.e., which cube map face, mipmap level, or 3D texture z-slice/depthoffset/image. Should we have one routine that handles all of these with some arguments ignored for specific texture types/targets? Or should we have a parallel set of routines for 1D/2D/3D, like TexImage does?

RESOLUTION: Option (b) 3 routines for texture, 1 for renderbuffer

Originally, we chose option (b) for reasons of similarity to glTexImage1D/2D/3D. For TexImage2D and FramebufferTexture2D, the texture target was used to select a face on a cube map texture object. Since glTexImage1D/3D used TEXTURE_1D/TEXTURE_3D texture targets, we did the same for FramebufferTexture1D/3D. We also included the texture target in case it was needed for future expandability.

However, some felt uncomfortable with this resolution since it adds 3 framebuffer attachment calls for textures, so we reopened the issue.

Originally we just considered options (a) and (b). We then reconsidered a few additional flavors: (c), (d), and (e)

```
             Options include:

             a) one routine with arguments that are sometimes "ignored"

                For instance <image> is ignored for non-3D textures
                and <face> is ignored for non-cube maps, etc.

                This gives us:

                void FramebufferTexture(enum target, enum attachment,
                                        uint texture,
                                        uint level, enum face, uint image);

             b) routines for 1D/2D/3D, use FramebufferTexture2D for 2D,
                Cube, Rectangle

                Requires use of a texture target to distinguish cube map
                faces on FramebufferTexture2D

                Includes "redundant" texture target for 1D/3D variants
                for consistency and precedent with TexImage1D/3D.

                This gives us:

                void FramebufferTexture1D(enum target, enum attachment,
                                          enum textarget, uint texture,
                                          uint level);
                void FramebufferTexture2D(enum target, enum attachment,
                                          enum textarget, uint texture,
                                          uint level);
                void FramebufferTexture3D(enum target, enum attachment,
                                          enum textarget, uint texture,
                                          uint level, uint image);

            c) same as (b) but add a dedicated routine for Cubemaps

               Question: since we added a Cubemap version, do we need a
               Rectangle variant as well?

                This gives us:

                void FramebufferTexture1D(enum target, enum attachment,
                                          enum textarget, uint texture,
                                          uint level);
                void FramebufferTexture2D(enum target, enum attachment,
                                          enum textarget, uint texture,
                                          uint level);
                void FramebufferTextureCubemap(enum target, enum attachment,
                                          enum textarget, uint texture,
                                          uint level);
                void FramebufferTexture3D(enum target, enum attachment,
                                          enum textarget, uint texture,
                                           uint level, uint image);
```

```
    d) same as (c) but with no texture target parameter

       Question: since we added a Cubemap version, do we need a
       Rectangle variant as well?

        This gives us:

        void FramebufferTexture1D(enum target, enum attachment,
                                  uint texture, uint level);
        void FramebufferTexture2D(enum target, enum attachment,
                                  uint texture, uint level);
        void FramebufferTextureCubemap(enum target, enum attachment,
                                       uint texture, enum face,
                                       uint level);
        void FramebufferTexture3D(enum target, enum attachment,
                                  uint texture, uint level, uint image);

     e) one FramebufferTexture routine with additional arguments
        passed in via another routine.

        There are no "ignored" arguments in this routine.

        The arguments which would be "ignored" by this function
        are passed in as selector state by a separate function.
        These could be specified as a FramebufferParameter
        (implying that they are stored as framebuffer state), or
        as a piece of context state that is copied into the
        framebuffer attachment point at FramebufferTexture time.
        Of the two, context state is much more desirable since
        ARB_render_texture made the mistake of putting the
        selection state in the pbuffer, and this has real
        usability issues for multicontext applications.

        This gives us (two routines)

        void FramebufferTexture(enum target, enum attachment,
                                uint texture, uint level);
        and

        void FramebufferParameter(enum target, enum pname, uint param);
            where pname can be one of
                GL_{attachment}_TEXTURE_CUBEMAP_FACE
                GL_{attachment}_TEXTURE_3D_IMAGE
            and param represents the cube map face or z-slice image.

        Also, option (e) raises 2 questions:

        1. Since the rest of the selection state would come in
           through another function, we have to ask when can
           these selector state variables be changed?

           We had previously decided that we want to pass
           selection state in atomically with the attachment
           request.  To be consistent with this earlier
           decision, this would imply that these variables could
           not be changed dynamically but would be "snapshotted"
```

```
            into the framebuffer attachment point at at
            FramebufferTexture time.  This snapshot could be
            thought of as similar to the way ActiveTexture works.
            This is also similar to the snapshot of the
            transformed raster pos vertex that occurs at
            glRasterPos time.  It is a copy of one piece of state
            into another piece of state, not just a "switch" than
            can be updated later that indicates where other state
            should be stored.

         2. Is the rationale to consolidate FramebufferTexture
            from 3 routines to 1 also a reason to consolidate
            FramebufferTexture and FramebufferRenderbuffer into a
            single attachment routine?  I.e., should there just
            be one routine called FramebufferAttachableImage()?

            If we did this, then we could also move <level> out
            of the argument list and rename the function to,
            perhaps, FramebufferAttach.

              void FramebufferAttach(enum target, enum attachment,
                                     enum objectType, uint name);
              and we'd need to create another enum for
              FramebufferParameter
                  GL_{attachment}_TEXTURE_LEVEL

              or, avoiding the use of verbs in the function
              name, perhaps:

              void FramebufferAttachableImage(enum target, enum attachment,
                                              enum objectType, uint name);

    Rationale:

    (a) was discarded because it was not very extensible in the
    event we need to add additional texture selection state in
    the future (for instance, what if we add TEXTURE_4D
    targets?)

    (c) and (d) were discarded because the introduction of a
    special cubemap routine was undesirable since we were
    considering issue in an attempt to *reduce* the number of
    entry points.  Additionally, (d) was discarded because it
    was felt the texture targets were still required.

    (e) was discarded because the intent was that attachment
    (and the consequent framebuffer validation) was a
    "heavy-weight" operation.  By using a separate routine to
    set part of the attachment state, developers may be
    incorrectly encouraged to assume some attachment state could
    be changed more easily than others.  It was felt it wasn't
    worth this possible misunderstanding just to save some
    function entry points.

    In the end, it was determined that (b) was the lesser of two
    (five?) evils.  (b) also has precedent in the specification
    of texture images via gl{Copy}TexImage.  Finally, (b) is
```

pretty clearly extensible to new attachment routines for future object types.

(12) Do we need a "format group" or "format restriction" API?

RESOLUTION: Yes, but put it in a separate extension for reasons of schedule.

This extension introduces the ability to construct a collection of logical buffers using images of various formats into a framebuffer in a very flexible manner. It is by design more flexible than used to be possible to do by querying for available pixel formats in the window-system glX/WGL/agl API's. As a result, it is possible to construct a framebuffer that is actually not supportable by the implementation and the reasons for the configuration being unsupportable are entirely implementation dependent.

This is why we originally added the CheckFramebufferStatus API. So that the application at least has the ability to determine that a particular, otherwise legal, configuration of framebuffer attachments actually will not work on this implementation.

However, this extension does not provide any very helpful mechanism to find out why things are not supported or what to do to reconfigure the attachments into a supported configuration.

This is a very difficult problem to solve. glX/WGL/agl solved this problem by allowing the application to specify a request for a configuration and letting implementation provide a "best match". Additionally, glX and WGL also allow for the enumeration of all possible supported configurations.

Various schemes like these were considered but they were all quite complicated (possibly as complicated as the windowing system API's we are trying to replace). Consequently, we decided to investigate some additional approaches.

One of these approaches is to specify "allocation and usage" hints prior to the routines which allocate buffers (TexImage/RenderbufferStorage) that will somehow indicate an intended configuration and then let the implementation use this additional information when selecting internal formats for textures and renderbuffers. The GL already has the freedom to pick any internal format it wants for textures and renderbuffers (subject to invariance requirements), and so we would like to leverage this freedom and influence the choice with an additional channel of information.

One example, though not the only one, is some API to let the application specify it would like to be able to use a color buffer, depth, and stencil buffer. The implementation would take advantage of this information when allocating textures and renderbuffers and only choose internal formats for color, depth, and stencil textures and renderbuffers that could be guaranteed to be used together. For instance, the user could call:

```
    FormatRestriction(GL_COLOR | GL_DEPTH | STENCIL);
```

or perhaps

```
    FormatRestriction(GL_32_BITS_COLOR_DEPTH_STENCIL);
```

and then when the user called TexImage with a color buffer, the GL would only pick color formats that could definitely be used with depth and stencil buffers. The effect of this API would be to "restrict" the avaible choices to the GL to the subset of compatible formats. In this way, the possibility of encountering an implementation-dependent reason for failing "framebuffer completeness" would be greatly reduced or perhaps entirely eliminated.

In any event, specifying this "FormatRestriction" API was going to take additional time and we wished to get this base EXT_framebuffer_object specification done and shipping as soon as possible. So we agreed to defer this "format restriction" API specification to a later extension, with the intent to develop this API or some other solution to this problem as soon as possible.

(13) Do we need intrinsic buffers in addition to renderbuffers?

RESOLUTION: no

When intrinsic buffers were initially proposed, the format and dimensions of an intrinsic buffer could mutate in order to provide compatibility with the other images attached to a framebuffer object. After much debate and a series of votes, intrinsic buffers had lost both of those properties. (See issue 36.) In the end the working group decided that the crippled form of intrinsic buffers do not provide enough added value to justify their existence.

(14) Is it necessary to require that all the logical buffers of a framebuffer object have the same dimensions?

RESOLUTION: Yes. Matching dimensions are required for simplicity. If the dimensions do not match, the framebuffer object will not be "framebuffer complete".

It could be useful to use a single large depth buffer when rendering to many textures of several different sizes. This is something that could be added later by a layered extension that relaxes the matching dimension restriction. Supporting heterogeneous sized logical buffers requires defining where in a larger buffer the smaller results are written, and deciding what guarantees can be made and what should be left undefined.

(15) *What happens when TexImage or CopyTexImage is called on a texture image that is attached as an image of the currently bound framebuffer object?*

RESOLUTION: resolved, {Copy}TexImage will redefine the texture image, which can affect the completeness of the framebuffer to which it is attached, and possibly cause the currently bound framebuffer to start failing the framebuffer completeness test.

As far as {Copy}TexImage (or RenderbufferStorage) are concerned, there is nothing "special" about a texture image (or renderbuffer) attached to a framebuffer object. Attempts to redefine attached images in this manner should succeed. However, if the redefined image is no longer appropriate for the relevant attachment point in the framebuffer it is attached to, then it's possible the framebuffer may start failing the framebuffer completeness test.

Another option that was considered involved having TexImage and CopyTexImage result in INVALID_OPERATION and do nothing when the target texture is bound for render-to-texture. This idea was rejected because, in the multicontext case, one context could change the attachments of a shared framebuffer and cause another context to suddenly start generating errors on {Copy}TexImage calls. This extension has tried to avoid introducing asynchronous generation of gl errors.

Still another option that was considered was "orphaning" the old texture memory such that it could still be used as a framebuffer attachment but the texture would get newly allocated storage. However, this implied a side-ways copy of the texture object memory or the image for its continued use as a framebuffer-attachable image, and was therefore rejected.

For the purposes of comparison, consider that ARB_render_texture faced a similar question and resolved it by implicitly unbinding the texture from the pbuffer when TexImage is called.

(16) *What happens when TexImage or CopyTexImage is called on a texture object that is attached as an image of a framebuffer object that is not bound to the current context?*

RESOLUTION: resolved, {Copy}TexImage will redefine the texture image, which can affect the completeness of the framebuffer object to which it is attached. When the framebuffer object is bound to the context, it may start failing the framebuffer completeness test. If the framebuffer object is bound in another context at the time {Copy}TexImage is called, then the framebuffer object may start failing the framebuffer completeness test in the other context.

The rationale for this decision is the same as for issue (15).

However, since in this case the relevant framebuffer is not current, there is no guarantee that this framebuffer revalidation or invalidation will happen until the next time the framebuffer is bound to a context.

The texture (or renderbuffer) state is changed immediately, regardless of whether the texture image (or renderbuffer) is attached to a framebuffer object. However, a context other than the one issuing the {Copy}TexImage operation might not notice the state change until after it has (re)bound the framebuffer object or reattached the texture image.

This is intended to be similar to what happens in the multicontext case when the state of a shared texture object is changed by another context. There is no guarantee that texture state change will be visible in the current context until the current context binds the texture object again.

(17) Why is render to vertex array missing?

RESOLUTION: Render to vertex array is separate functionality from render to logical buffer or render to texture. RTVA can be added as a separate extension. The framework is general enough to support more than one way of adding RTVA, without deciding today on the details of a particular RTVA implementation.

One idea is to define a way to interpret a vertex array or buffer object, which is inherently byte-oriented linear, as a framebuffer, which is inherently component-oriented and dimensioned, and then call FramebufferArrayEXT like this:

```
FramebufferArrayEXT(FRAMEBUFFER_EXT, COLOR, buffer_obj);
```

Another idea is to define a general way to interpret a component-oriented dimensioned image, such as a texture or a color buffer, as a byte-oriented vertex stream. Using this approach one would render vertex attributes to a renderbuffer, to a texture image, or to an AUX buffer, and then use the image data directly as a vertex array.

There is controversy over which RTVA method(s) should be supported. One goal of EXT_framebuffer_object is to ship render-to-texture and render-to-logical-buffer functionality today while leaving the door open to add one or more RTVA solutions in the future.

(18) What function should perform the action of attaching a texture image to a framebuffer for rendering purposes?

RESOLUTION: The new FramebufferTexture*EXT functions perform this action.

Options that were considered include overloading BindTexture, using a FramebufferParameter function, and adding a new function.

BindTexture is problematic because it creates a new texture object with default state if the name is previously unused, but the default state has no dimensions, dimensionality, or format.

One reason that FramebufferTexture*EXT was well-received is because it sets, in one atomic operation, all framebuffer attachment state for both texture image and renderbuffer type of attachments. Given the polymorphic nature of framebuffer-attachable images, this guarantees that all framebuffer attachment state is in a consistent configuration, without having to define confusing precedent rules between competing (texture image and renderbuffer) pieces of framebuffer attachment state, or having to create enables (either a tri-state enable or separate enables again with precedence) to select texture image or renderbuffer attachment state as the "active" set of state.

This decision also makes it simpler to specify how a framebuffer-attachable image is detached from a framebuffer--it would be confusing if detaching a texture image resulted in *attaching* a renderbuffer simply because texture image attachment state takes precedence over renderbuffer image attachment state.

(19) What should happen if the texture argument given to FramebufferTextureEXT is an unused texture name? And similarly, what should happen if the renderbuffer argument given to FramebufferRenderbufferEXT is an unused renderbuffer name?

RESOLUTION: resolved, (a) this is an error.

Options included:

a) throw an error at Framebuffer{Texture|Renderbuffer}

b) texture/renderbuffer is created just like Bind{Texture|Renderbuffer}

c) no error, but the framebuffer cannot be "framebuffer complete" until a texture/renderbuffer by that name has been created and satisfies the rules of framebuffer completeness.

This is interesting because on the one hand we might like to adopt the model that we simply catch all the invalid state combinations when determining framebuffer completeness, i.e., option (c). This has a certain consistency but then what does it mean to call FramebufferTexture{1D|2D|3D} when the target of the texture name is not yet known? How should the other arguments to those calls be validated?

Option (b) was rejected as it would introduce a second way to create a texture/renderbuffer object. I.e., both

BindTexture and FramebufferTexture would create the texture object.

Since there are "target aware" FramebufferTexture{1D|2D|3D} calls, the app already has to know the target prior to calling FramebufferTexture. Also, the texture target of a given object is immutable once set. An app can not set it and then change it later so this is really just an issue with the order in which they call the relevant functions. Consequently, requiring that the user call BindTexture prior to calling FramebufferTexture does not seem to be a burden. So this should be an error, since it's probably a mistake on the user's part in the first place.

(20) What should happen if the texture argument given to FramebufferTextureEXT is the name of an existing texture object, but the texture has no texture image (i.e., TexImage has never been called)? Similarly what should happen if the renderbuffer argument given to FramebufferRenderbufferEXT is the name of an existing renderbuffer, but the named renderbuffer has no storage (i.e., RenderbufferStorage has never been called?)

RESOLUTION: resolved, option (c) - no error, but the framebuffer object cannot be "framebuffer complete" until the state of the texture image satisfies the rules of framebuffer completeness.

Same options as issue (19), these include:

a) throw an error at Framebuffer{Texture|Renderbuffer}

b) texture/renderbuffer is created just like Bind{Texture|Renderbuffer}

c) no error, but the framebuffer cannot be "framebuffer complete" until the texture image or renderbuffer satisfies the rules of framebuffer completeness.

This is an issue because you could be attempting to attach a texture (or renderbuffer) to a framebuffer attachment point prior to the application having called TexImage (or RenderbufferStorage) to define the width/height/format of the framebuffer-attachable image.

At first, this seems similar to issue (19), so we could throw an error in this case too. It is different for two reasons however. First, there are default values for the texture object and renderbuffer object state. Second, the values of the width/height/format/etc for the texture object are mutable, unlike the texture target of the texture object. There is really no difference between the case where GL uses the default values for an object, and the case where the user explictly set the state equivalent to the default values using TexImage (or RenderbufferStorage). Because this state is mutable, it must be tested anyway when framebuffer completeness is determined.

Therefore, we simply defer the check for whether the texture/renderbuffer state is appropriate for the framebuffer attachment point until determination of framebuffer completeness. If the state is not valid, then the framebuffer will not be complete, regardless of whether or not TexImage/RenderbufferStorage has been used to create storage for the texture level (renderbuffer).

(21) *What happens when DeleteTextures is called on a texture that is attached to a framebuffer object? Similarly, what happens when DeleteRenderbuffers is called on a renderbuffer that is attached to a framebuffer object?*

RESOLUTION: resolved, see issue (77)

(22) *How do you detach a texture or renderbuffer from a framebuffer object? Should we use two routines or create a detach routine?*

RESOLUTION: resolved, 2 routines

If the user calls either FramebufferTexture with a zero texture name, or FramebufferRenderbuffer with a zero renderbuffer name, then the it as if nothing is attached to the specified attachment point.

There was a concern that having two routines be able to set the framebuffer attachment state to "none" was confusing. However, the idea is simply that for any object that can be attached to a framebuffer, there should be a routine that can set up the attachment and return the framebuffer to the default "nothing attached" state.

The implication here is that the default state for framebuffer attachments is:

```
    attachment object type = GL_NONE, and
    attached object name   = 0
```

(23) *Should it be legal for the framebuffer state to pass through invalid configurations? (I.e., depth and color buffer sizes don't match, etc)*

RESOLUTION: resolved, "yes"

It's easier for the application if the render target state is allowed to pass through invalid configurations when transitioning between two valid configurations. A consistency check is defined to determine if a configuration is valid.

As long as everything is valid at render time, transient invalid states are allowed.

(24) What happens when you try to draw to a framebuffer that is not "framebuffer complete"?

RESOLUTION: resolved, rendering is disabled, and an error is generated. See issue (64) as this issue is essentially a duplicate of that one.

(25) What should happen on a query of framebuffer state while the framebuffer is invalid? For instance, what does a query of RED_BITS return if the currently bound framebuffer is not "framebuffer complete"?

RESOLUTION: resolved, there's no issue here. Attempts to query bit depths should return the "real" answers.

For instance, if there's no color buffer attached to the framebuffer attachment point, then attempts to return RED_BITS could return zero. If there is a color-renderable image attached, then RED_BITS would return whatever the RED_BITS are, regardless of the valid/invalid state of the framebuffer.

Other options include returning some kind of magic value or generating an error if the framebuffer is invalid. However, any "magic value" would simply be a duplicated query for the framebuffer completeness status. Also, returning an error would be problematic because another context can make a framebuffer invalid and we have been trying to avoid any API in which one context can cause another context to start generating errors asynchronously.

(26) What happens when you try to read (e.g. ReadPixels) from a framebuffer that is not "framebuffer complete"? Reads cannot be "disabled" or "ignored" in the same way that rendering can.

RESOLUTION: resolved, generate a GL error. See issue (65).

Originally this was resolved as "undefined pixels are generated, but no error"

Initially, generating an error was rejected for a few reasons. First, it is asymmetric with the behavior for drawing - when the framebuffer is not complete, drawing is disabled. We would like to be consistent here. Second, there are no other cases where ReadPixels or CopyTex{Sub}Image will generate an error based on the state of the framebuffer and we didn't want to introduce one. Third, there is already a pixel ownership requirement in order to get defined results back from reading the framebuffer, so if we simply behave as if incomplete framebuffer fails ths pixel ownership test, then we can leverage that already specified behavior for reading the framebuffer.

For these reasons, we initially choose to have reads from an incomplete framebuffer return undefined pixel values and not generate a GL error.

However, once we subsequntly resolved issue (64) to say that rendering with an incomplete framebuffer generates an error, we decided again for reasons of symmetry that reading from an incomplete framebuffer should also generate an error. (And most likely the same error.)

So in the end, we decided that reads (e.g., ReadPixels and CopyTex{Sub}Image) in this case would result in an error to be named in issue (65).

See also related issue (73), describing ReadPixels of color data from a complete framebuffer while READ_BUFFER is NONE.

(27) What happens when you query the number of bits per channel (e.g., DEPTH_BITS) prior to the consistency check being run when intrinsic buffers are in use, since implementations are allowed to select a number of bits for an intrinsic buffer at consistency check time to give a better chance of a consistent state being reached?

RESOLUTION: This is not an issue since we don't have intrinsic buffers, see issue (13). We are keeping this issue in the issues list just in case we ever go back and add something like this to a future API.

If we would have retained the intrinsic buffer api (i.e., glFramebufferStorage) or if some future API adds it back in, then one possible resolution of this problem would have been to simply say that a query of the number of bits prior to the consistency check being run will produce an answer that is subject to change.

This is preferable to some other possible resolutions that have been discussed (e.g., having the query cause a validation to occur implicitly, thereby "baking" in the answer) because it is the one least likely to introduce unexpected side-effects to an operation as seemingly innocuous as a query.

A possible variant of this proposed resolution would have been to have the query return a number of bits that is guaranteed to be less than or equal to the actual number of bits that will eventually be used. This may or may not be a useful guarantee. We could have also had the query return 0 or -1 as a signal that the framebuffer is incomplete.

Again, this is all moot since we decided against this style of intrinsic buffers in this extension.

(28) What should the <image> parameter to FramebufferTexture3DEXT actually be called?

RESOLUTION: resolved, "zoffset"

This parameter could have been called <image> or <slice>. <depth> or <zoffset> might also be appropriate. The reason the answer here is non-obvious is that normally 3D textures are specified all at once, not one 2D "slice" at a time (TexImage3D takes one big array that represents all three dimensions at once, for example), and because texture coordinates for TEXTURE_3D targets are normalized floating-point numbers, just as they are with TEXTURE_2D targets, not integer indices.

The GL uses the term "image" to mean "slice" in a few instances. For example, pixel unpack parameters UNPACK_SKIP_IMAGE and UNPACK_IMAGE_HEIGHT describe state related to the "slices" a 3d texture.

However, in some ways the act of rendering into a texture is most similar to CopyTexSubImage3D, which also redefines a texture's contents (but never its format or dimensions) based on the contents of the framebuffer. The "zoffset" parameter to CopyTexSubImage selects a particular 2D image (depth "slice") of a 3-dimensional texture. "zoffset" is a coordinate, and the parameter to FramebufferTexture3DEXT is also a coordinate. "Image" typically refers to an array of pixels.

We already use the term "image" throughout this extension to talk about 2d arrays of pixels beyond their use in 3D textures. It is a little confusing to overload "image" to also mean Z coordinate in FramebufferTexture3DEXT.

For the sum of these reasons, we decided "zoffset" is a better name than "image", for the parameter to FramebufferTexture3DEXT.

(29) Should GenerateMipmap functionality be included in this extension or put in it's own extension?

RESOLUTION: resolved, yes, include this functionality

It is arguably useful separately, i.e., without all this machinery. However, it's also kind of required here to have some kind of way to deal with the interaction with SGIS_generate_mipmap. Probably we should just include it here. (maybe also a separate extension?)

It's easier to define when automatic mipmap generation happens for a traditional non-rendered texture than it is for a texture that is modified by rendering-to-texture. If GENERATE_MIPMAP were to cause a rendered-texture's mipmaps to be automatically generated, presumably generation would occur when either the texture is detached from the framebuffer or when the framebuffer is unbound. If neither of these events occur, should automatic mipmap generation also occur when the texture is bound to a texture unit (of same or different context?)

It's believed the recommended way of achieving maximum performance using this extension is to make all attachments during initialization, and then not change attachments in the steady state. This reasoning is, after all, a major reason for introducing framebuffer objects. If an application does not detach textures from framebuffers, then what event triggers mipmap generation? An explicit GenerateMipmap works well here.

Would the base level have to actually be modified in order for mipmap generation to occur? How should "modified" be defined?

If the application rendered to each level of the texture before detaching the texture or unbinding the framebuffer, would automatic mipmap generation happen anyway? (This implies the application needs to set GENERATE_MIPMAP to FALSE before rendering to the texture, but maybe that's OK.)

Historical background: One reason for introducing GenerateMipmap in the context of the original uber_buffers proposal was that uber_buffers lacked a Begin-time consistency check, but instead prevented the framebuffer from ever getting into an inconsistent state (once validated). Operations such as TexImage that can change the dimensions and format of a tetxture's levels were disallowed when the texture was attached to a framebuffer. Since automatic mipmap generation can change the dimensions and format of a texture's levels, that meant that automatic mipmap generation could not be performed in some cases, but there was no good way to communicate this error to the application. Hence there really was a need for a separate GenerateMipmaps function. This restriction does not apply to the current API because the semantics of an incomplete framebuffer are different now. Nevertheless, we decided to retain this manual mipmap generation as part of this extension.

(30) Do the calls to deal with renderbuffers need a target parameter? It seems unlikely this will be used for anything.

RESOLUTION: resolved, yes

Whether we call it a "target" or not, there is *some* piece of state in the context to hold the current renderbuffer binding. This is required so that we can call routines like RenderbufferStorage and {Get}RenderbufferParameter() without passing in an object name. It is also possible we may decide to use the renderbuffer target parameter to distinguish between multisample and non multisample buffers. Given those reasons, the precedent of texture objects, and the possibility we may come up with some other renderbuffer target types in the future, it seems prudent and not all that costly to just include the target type now.

(31) What should happen if you call FramebufferTexture{1D|2D|3D} with a texture name of zero?

RESOLUTION: This will detach the image from the specified attachment point in the currently bound framebuffer object.

For reference, this reason this is problematic because there is not really a "texture object zero"

Texture name zero does not define an object but defines context state (one texture named zero, per target, per context). The textures referred to by the name zero are never shared across contexts. So the behavior of framebuffer objects shared by multiple contexts where each is attached to the context's texture named zero seems odd at best, and confusing at worst. As such, it was decided to not allow a framebuffer to attach to texture named zero.

Another option would have been to make this an error. If we had done this, then we would need a specific function to detach a texture from an attachment point. That is, we would have needed to create something like a dedicated DetachFramebufferAttachableImage() entry point.

(32) Should there be a renderbuffer object with the name of zero?

RESOLUTION: NO.

By way of symmetry with textures, renderbuffer zero, if it existed, would not be an object. It would be a non-shareable piece of the context state. There would be one renderbuffer named zero per target per context.

If we can't share renderbuffer name zero, then also by way of symmetry with textures, we would not want to support attaching renderbuffer name zero to a framebuffer.

So, if it can't be used as a rendering destination, then a renderbuffer name zero would seem to serve no purpose as a state container.

However, we'd like to retain the use of name zero in certain routines with special semantics, particularly for detaching non-zero renderbuffer objects from the framebuffer and context. See issue (33).

On implication of this decision is that state setting/getting routines that operate on the currently bound renderbuffer should throw a GL error if no renderbuffer is bound/attached. A similar choice was made in the ARB_vertex_buffer_objects specification which also had special semantics for object zero.

Also note, another option considered was making object zero a full fledged, shareable object just like the non-zero object names. This was rejected as being too different from texture/program vbo's/etc., possibly leading to confusion.

(33) What should happen if you call FramebufferRenderbuffer or BindRenderbuffer with a renderbuffer name of zero?

RESOLUTION: This will detach the image from the specified attachment point in the currently bound framebuffer object.

This is resolved exactly the same way as issue (31) was resolved for textures, and for the same reasons.

Similarly, calling BindRenderbuffer with a name of zero will unbind the currently bound renderbuffer from the context.

(34) Should there be a way to query a framebuffer object for its attached texture and/or renderbuffers? If so, how, and what should be the query result when attached textures or renderbuffers have been deleted?

RESOLUTION: resolved, yes

In general, OpenGL lets you query settable state, so we allow this.
To see what this query should look like, see related issue (51)

This issue also raises the question about what values should be returned for attached objects if the named objects have since been deleted. This can happen if the textures were attached to non-currently bound framebuffers or attached to framebuffers in other contexts. Three possible solutions include:

a) Don't support this query.

b) Return zero if no texture has ever been attached. Return zero if the attached texture has been deleted.

c) Return zero if no texture has ever been attached. Return the name of the texture that was attached even though it has been deleted.

Option (a) was rejected as we would like settable state to be queriable.

So, for this extension originally we choose option (c). However, we have since decided, in issue (21), that DeleteTexture and DeleteRenderbuffer will first detach the texture/renderbuffer from any attached framebuffer objects *in this context*. In principle, the application can't tell the difference between the texture getting deleted now or later, so whether the texture is actually detached from the current framebuffer now and other framebuffers when they are bound, or the texture is actually detached from all framebuffers at once is moot. In practice, this means that options (b) and (c) are essentially indistinguishable for a single context case.

However, it's worth noting that if the texture is deleted and attached to a framebuffer which is current in another context, the standard rules about undefined behavior of state modifcations of shared objects in other contexts will still applye.

This means that the texture may or may not be detached (and thus deleted) from that other context's current framebuffer until the next BindFramebuffer (or FramebufferTexture/FramebufferRenderbuffer?) in the other context.

(35) Earlier proposals included a way to create some memory and then attach it to a texture object. Should this extension include this feature?

RESOLUTION: no.

This was considered when this extension was intended to be a more general purpose memory manager. Since this extension has been retasked to focus in on render-to-X functionality, this feature was not necessary.

(36) Earlier proposals had renderable memory constructs which could change internal format or dimensions to meet intra-framebuffer compatibiltiy requirements of individual vendors' hardware platforms. Should this extension have these kind of malleable format objects?

RESOLUTION: no.

Such malleability leads to invariance problems when formats change. For example, if bits per pixel is decreased then increased back to the original value, some precision is lost.

Some IHVs wanted to require format conversion of existing contents in all cases where the format changes. This sort of invariance would be an acceptable side-effect. The suggestion was to think of the action of rendering to a texture as an extended non-atomic TexImage call. TexImage is allowed to change the format of an existing texture image. It was claimed that such intrinsic buffers are more convenient in many applicaitons than are the explicitly managed renderbuffers.

Other IHVs expressed a strong opinion against implicit format conversions, but instead wanted to invalidate the buffer's contents whenever the format changed. It was difficult to define the set of operations that might cause the format to change, so it was difficult to define when the contents could become invalidated. If the contents were invalidated by a format change, the API under consideration made it cumbersome for the application to detect and handle this condition. In the end, under the buffer content invalidation approach, application code would not be any better off than if the appliation instead used the explicit renderbuffers. For the type of intrinsic buffers that could not change format and dimensions dynamically, the claim that intrinsic buffers were more convenient than renderbuffers was no longer true.

The working group voted for the latter: no implicit format changes. Instead the format would be immutable once it is known.

A secondary issue is the question: are the buffer contents invalidated when the dimensions change, are the contents scaled, or are the contents are clipped/padded (with some sort of gravity). This issue could be avoided by requiring explicit, rather than implicit, resize of intrinsic buffers.

The working group voted for no implicit change in the dimensions of intrinsic buffers, and finally for the removal of intrinsic buffers altogether.

(37) In order to abstract hardware dependent compatibility requirements, this API introduces a function called CheckFramebufferStatus to check for compatibility prior to rendering. CheckFramebufferStatus returns a value which indicates whether or not the framebuffer object is "framebuffer complete", and framebuffer completeness depends in part on hardware dependent constraints. The hardware dependent aspect represents a new concept in OpenGL. Therefore, should an app be required to call this function to help "enforce" the notion that apps should be on the lookout for failure?

RESOLUTION: no. Calling CheckFramebufferStatus is not required.

The group considered requiring a call to CheckFramebufferStatus after changing framebuffer state or attachment points in order to "enable" rendering. It was hoped that requiring a call to CheckFramebufferStatus would push developers to write code which is more platform independent. Ultimately though, since the API can't require applications to actually observe and deal with a validation failure, that it was not worth it to make this function call required. There was also feedback from some developers that requiring this call would be cumbersome and undesirable.

Note, however, that the framebuffer is effectively validated implicitly at every rendering (and reading) entry point. These include glBegin, gl{Multi}Draw{Arrays|Elements}, gl{Draw|Copy|Read}Pixels, glCopyPixels, glReadPixels, glCopyTex{Sub}Image, etc.

Applications are strongly advised to test framebuffer completeness with CheckFramebufferStatus after setting up or changing the configuration of a framebuffer object, and to handle the possible failure cases with a fallback plan that selects a different set of internal formats of attached images. See usage example 6. Section 4.4.4.2 lists the operations that can cause the framebuffer's status to change.

In addition, a "format group" API, has been proposed as a means of programmatically determining a set of internal formats that are guaranteed to be compatible with respect to framebuffer completeness. This API would be specified in a layered extension as suggested in issue (12)

(38) Do we need to support multiple render targets, i.e., ARB_draw_buffers?

RESOLUTION: Yes.

ARB_draw_buffers is going to be part of OpenGL 2.0 so we'd better support it.

(39) How should we support ARB_draw_buffers?

```
RESOLUTION: refactored into the following issues:
            (53), (54), (55), (56), and (57)
```

(40) (How) should we support accum buffers?

RESOLUTION: defer this until (shortly) after this extension.

Accum buffers appears to be very simple to specify and implement. Basically, we would need to add a new internal ACCUM format that can be passed to RenderbufferStorage. We would also need to add an ACCUM attachment point in the framebuffer that could be used to point to one of these ACCUM format renderbuffers. A new ACCUM format is needed because the ACCUM buffer is defined by GL to be signed floating point value, unlike other internal formats.

Also note, the above solution is the exact same one we are using for STENCIL buffers as well (i.e., an internal format enum and an attachment point).

We could also decide if this new ACCUM internal format can be used with textures in addition to renderbuffers, for creating images that can be attached to the accum buffer attachment point.

Supporting accum was deferred for this extension, primarily for time-to-market reasons, and as it was not critical for most render-to-texture applications. However, we intend to work on some kind of "EXT_accum_renderbuffer" extension shortly.

Since this was deferred, we need to define what happens when you call the various Accum operations on a non-default framebuffer object. We considered adding spec language that would generate an error on Accum operations. However, it seems like we can simply leverage whatever legacy behavior is currently defined for when the pixel format has no accum buffer. This is the case in this extension as we have defined no way to attach or enable an accum buffer. Chapter 4 on page 188 already says that "If there is no accumulation buffer, or if the GL is in color index mode, Accum generates the error INVALID OPERATION", so we don't actually need any additional language of our own.

(41) (How) should we support multisample buffers?

RESOLUTION: defer this until (shortly) after this extension.

Supporting multisample was deferred for this extension, primarily for time-to-market reasons and because it's not entirely clear what is the "best" API for exposing multisample. However, we intend to work on some kind of "EXT_multisample_renderbuffer" extension shortly.

Since this feature was deferred, we need to define what happens when you try to enable multisample on a non-default framebuffer object. For now we need some way to *not* do multisampling. This can either be that we set SAMPLES 1 and SAMPLE_BUFFERS to 0, or we say that Enable/Disable(MULTISAMPLE) is ignored. This is actually related to issue (62) - should SAMPLE_BUFFERS change when using a non-default framebuffer or when attachments change? When/if we define and export "EXT_multisample_renderbuffer" extension, this state will again have significance.

A discussion of how we might support this feature follows:

There are several considerations here: First, we'd like something simple to specify, implement, and use. Second, we'd like to not delay this extension's approval, implementation or adoption for this particular feature. Third, we are trying to replace pbuffer functionality, which does support multisampling (at least in principle), so we'd like to not take a step backward in functionality if possible.

However, this extension is *not* trying to "improve" the traditional multisample support. If we do anything, we will simply expose the existing multisample buffer semantics without causing undue implementation burden.

Finally, if an implementation is currently taking short-cuts to GL's traditional "per-pixel-resolve" multisample semantics, we'd like for this extension to continue to allow the exact same short-cuts (to whatever extent the core GL spec does or does not allow those short-cuts). If someone later decides to go an revamp multisampling support in general, they can update this extension at the same time.

Given the above, it appears that the options include:

A) Don't support it. In other words, you can't use mulitsampling and EXT_framebuffer_object. The multisample state is either ignored, or causes the framebuffer to not be complete, or generates some kind

```
            of error.

         B) Create a separate multisample renderbuffer that can be
            attached to a new framebuffer attachment point.

            The reason that we might need a separate
            RESOLUTION_BUFFER is that all renderable color buffer
            formats might not be usable for multisampling on all
            implementations.

            Also, this option would allow multiple framebuffers to
            share the storage for multisample buffers under the
            control of the application.

            Depth sample buffers and stencil sample buffers
            wouldn't necessarily need resolution buffers, but that
            could be added by some future extension.

            This option has several variants:

              B1) Create MULTISAMPLE and/or RESOLUTION_BUFFER
                  internal formats for renderbuffer objects that
                  can be used with RenderbufferStorage.  The
                  samples buffer and the resolution buffer would be
                  allocated and attached to the framebuffer
                  separately.  Having them be separate allows the
                  samples to be deleted after rendering if desired.

                  One issue with this option is that somehow you'd
                  need to specify the number of samples maybe using
                  glFramebufferParameter or
                  glRenderbufferParameter.

              B2) Perhaps, instead of using a single internal
                  format called MULTISAMPLE, use a set of internal
                  formats like MULTISAMPLE_1_SAMPLE,
                  MULTISAMPLE_2_SAMPLE, MULTISAMPLE_4_SAMPLE, etc.
                  This is problematic for supporting depth/stencil
                  multisampling unless we want an explosion of
                  color/depth/stencil multisample internal formats.
                  It's also problematic if MRT draw buffers need to
                  be multisampled because we'd need a number of
                  enums able to support 1 to N draw buffers times
                  the number of sample patterns we support.

              B3) Have RenderbufferStorage always take a number of
                  samples.  We could do this if option (B2) is
                  insufficient due to the need to support DEPTH or
                  STENCIL multisampling, which we probably will.
                  We would then allow the internal format to choose
                  DEPTH, STENCIL, or RGBA/etc.  This is clean but
                  it means that the user would always need to
                  specify a number of samples even when the value
                  is "1".

              B4) Pass in a variable length argument list to the
                  renderbuffer allocation routine, and some of the
```

```
                arguments would indicate intended usage
                (COLOR/DEPTH/MULTISAMPLE) others would indicate
                internal format (RGBA/DEPTH24) and others would
                indicate number of samples.  This is how
                EXT_compromise_buffers dealt with this problem,
                though people didn't seem to like this variable
                length argument list.  EXT_render_target didn't
                deal with this problem so doesn't offer any
                guidance here.

            B5) Create a new RENDERBUFFER_MULTISAMPLE
                renderbuffer target type and a corresponding
                allocation routine, perhaps called
                RenderbufferMultisampleStorage().  This is
                analogous to how textures have their own
                allocation routine per target type
                (TexImage1D/2D/3D, etc).

                With this option, we could preclude
                non-multisample targets from being attached to
                non-multisample attachment points as well.

            B6-B10) Any of the above options can be implemented
                    with either a single monolithic mulitsample
                    buffer that contains the samples for all draw
                    buffers, depth and stencil and a single
                    attachment point, *OR* with independent
                    multisample buffers for each draw buffer and
                    depth and stencil and independent attachment
                    points for each.

        C) Use some kind of "behind the scenes" mulitsample buffer.

           This option also has several variants:

            C1) An "implicit" multisample buffer that is simply a
                property of the framebuffer object.  Each
                framebuffer object could have its own multisample
                buffer(s).  Multisampling would be enabled with
                some kind of FramebufferParameter call.  This
                implies that each framebuffer has memory
                allocated with it.  It further implies that the
                contents of the multisample buffer are
                framebuffer state and are thus retained with the
                framebuffer object.

            C2) We don't say anything except that we say the
                value of the glEnable(MULTISAMPLE) is still
                respected and we render as directed.  This is
                similar to (C1) but we don't go so far as to say
                that the multisample buffer(s) is/are retained
                per framebuffer object.  In other words, a call
                to BindFramebuffer() and changes to framebuffer
                attachments may or may not retain multisample
                buffer contents.  Valid implmentations of this
                would include a multisample buffer per
                framebuffer or one per context.
```

```
          D) something else (hopefully simpler?)

    (42) What set of framebuffer targets should the initial extension
         support?

            RESOLUTION: resolved, (D) single target

            Basic possibilities include:

            (A) DRAW_AND_READ_FRAMEBUFFER_EXT

            (B) DRAW_FRAMEBUFFER_EXT
                READ_FRAMEBUFFER_EXT

            (C) DRAW_FRAMEBUFFER_EXT
                READ_FRAMEBUFFER_EXT
                DRAW_AND_READ_FRAMEBUFFER_EXT

            (D) FRAMEBUFFER_EXT

            The fundamental question is: must framebuffer binding points
            mimic the expressiveness of the window-system function
            MakeContextCurrent, which is described in the glX spec and
            the ARB_make_current_read extension?

            It was not immediately clear how to specify the distinction
            between a READ and a DRAW framebuffer in the context of the
            existing read/draw buffer semantics, given that this
            extension relaxes the "compatibility" requirement between
            read and draw drawables.  How would the value of RED_BITS
            for the read framebuffer be queried if it is different than
            the value of RED_BITS for the draw framebuffer?  What
            exactly is the set of implementation dependent state (see
            the "Implementation Dependent *" state tables in chapter 6)
            that can differ between read and draw framebuffer objects?

            When using MakeContextCurrent, the context's and drawable's
            FBconfig (or pixel format) must be "compatible" or else the
            results are implementation dependent.  But
            EXT_framebuffer_object cannot afford to swing such a large
            "undefined" stick, because it is more likely that
            framebuffer objects are incompatible in this sense, and
            because the "pixel format compatility" of a framebuffer
            object is dynamic--by changing attachments or redefining the
            internal format of an attached texture image.

            The value added by ARB_make_current_read through
            MakeContextCurrent is less relevant to
            EXT_framebuffer_object.  EXT_framebuffer_object enables
            rendering to a texture, and textures are objects with a
            clearly defined mechanism for use as the source of a pixel
            copy: rather than using CopyPixels to move pixels from the
            READ_BUFFER to the DRAW_BUFFER(s), an application can simply
            use the source data as a texture and then draw a
            screen-aligned textured quad to the framebuffer.
```

Additionally, adding separate DRAW and READ bindings in the future is pretty straightforward. One solution would be to say that FRAMEBUFFER_EXT is the DRAW framebuffer, and name the new READ framebuffer FRAMEBUFFER_READ_EXT. Add a new BindFramebuffer-like function which takes two framebuffer names--one for DRAW and one for READ. The current BindFramebuffer function binds a single object to both FRAMEBUFFER_EXT and FRAMEBUFFER_READ_EXT.

So, we defer the additional targets until need has been proven, and go with the simpler option (D) for now.

(43) *In order for a framebuffer object to be "framebuffer complete", must all textures attached to the framebuffer be mipmap complete (or mipmap cube complete if cubemap texture)?*

RESOLUTION: resolved, no

The reason this is a consideration is that some architectures require framebuffer-attachable images to be located in graphics memory when rendered to, and it may be more convenient to allocate and store a texture in graphics memory only if the texture is mipmap (cube) complete--i.e., the size and format of all levels are consistent in the normal sense of texture compeleteness.

However, since framebuffer attachment points only really deal with single images of a texture level, it seems excessive to require the state of the other levels of a texture to affect the validty of the framebuffer object itself.

Addtionally, the same difficulties around "incomplete" textures already apply to traditional CopyTexSubImage, and we have been trying to make the render-to-texture semantics similar to CopyTexSubImage.

Therefore, we chose not to treat render to texture any differently than CopyTexSubImage and do not require that the attached texture is mipmap (cube) complete.

(44) *What should happen if a texture that is currently bound to the context is also used as an image attached to the currently bound framebuffer? In other words, what happens if a texture is used as both a source for texturing and a destination for rendering?*

RESOLUTION: resolved, (b2) - results are undefined because the framebuffer is not "framebuffer complete".

Originally this was resolved as causing framebuffer to fail the completeness test--i.e., rendering would be disabled (b1)

As background, the reason this is an issue in the first place is that simultaneously reading from, and writing to, the same texture image is likely to be problematic on multiple vendors' hardware without paying performance penalties for excessive synchronization and/or data copying.

There are, however, certain cases where this functionality would arguably be useful, supportable, and well-defined. In particular, we can consider the case of custom mipmap generation using one level's image as source data to render into other levels of the same texture.

So, at a minimum, we would like to support rendering to a currently bound texture object if the source texture object has the BASE_LEVEL and MAX_LEVEL texture parameters set such that the level being used as a framebuffer-attachable image is excluded from texture fetches.

This was our original rationale:

a1) is problematic because one context could modify the base/max level on a shared texture causing another context which is using the texture as a destination to throw an error. This idea was rejected as it essentially meant that the error would need to be thrown at render timer which people found unacceptable.

b1) has the same kind of multicontext behavior but no error. One context can cause a framebuffer shared in another context to become invalid, but this is already true and can happen for a variety of reasons if the participating framebuffer-attachable images and/or framebuffer attachments are modified by either context.

At the time, we also considered the following questions: should the specification require the framebuffer to fail the framebuffer completeness test? Or is the framebuffer simply "allowed" to not be complete in this case? The latter choice would imply that the framebuffer might still be considered "framebuffer complete" on some implementations. See issue (46)

c1) is the easiest to specify and has an advantage that some implementations may be relying on this behavior already. However, this was rejected as it is the least portable of the three options.

We originally chose option (b1), though we considered that later on, individual hardware vendors may offer layered extensions that change this "framebuffer completeness" failure into a success with either defined or undefined rendering behavior.

However, this issue was re-opened becaues the subsequent resolution of issue (66) was that there should be no "context-dependent" reasons for framebuffer incompleteness. If we had stuck with option (b1), then we would be making the framebuffer completeness predicated on a piece of context state (the current texture binding). Consider the case where texture T is attached to a framebuffer. Then this would have meant that a framebuffer could be complete in one context (that didn't have texture T bound as a texture) and incomplete in another context (that did have texture T bound).

When reconsidering this issue, we realized that we would not throw an error at Begin time without disabling rendering, so we really only considered the following revised set of options:

a2) throw an error and disable rendering, but don't affect framebuffer completeness
b2) the behavior is undefined

The issue was resolved the second time as:
b2) Undefined behavior

Another option that was briefly considered was to make this another type of error (unrelated to trying to render with an incomplete framebuffer). However, part of the rationale for throwing an error at glBegin time when trying to render with an incomplete framebuffer was that if you already have to test for framebuffer completeness, then throwing an error is no additional implementation burden. Yet, since it was decided that the "texture-from-destination" condition is not part of framebuffer completeness - issue (66) - then it is an additional burden to perform the "texture-from-destination" check just so that an error can be generated. The concern was some implementations might not need to check for this case at all and we didn't want to burdern those implementations with an additional Begin-time error check.

Also, for what it's worth, if we had left the "texture-from-destination" case in the framebuffer completeness test then any language describing how framebuffer completeness is affected when a currently bound texture is used as both source and destination needs to be explicit that the texture has to be currently bound *and* enabled. For instance, consider the case where a user has a cubemap texture object name N bound to unit X and a 2D texture object name M also bound to unit X. What if the user would like to use the 2D texture M as a source while rendering to the faces of the cubemap texture N? We would like to support this scenario, so the language about a currently bound texture object would have needed to take the target into account. And to make matters more interesting, this means we would have needed to take texture enables and fragment shaders into account in this decision. In the end, we decided that "context-state" would not affect the defintion of framebuffer completeness we avoided this complexity (or at least moved it out of the framebuffer completeness test).

(45) Are framebuffer configurations with no color attachments allowed?

RESOLUTION: resolved, yes

The reason this is an issue is that the GL spec assumes there is always a color buffer. If a framebuffer with no images attached to any of the color buffer attachment points can be "framebuffer complete", then the core GL spec will need to be modified to relax the assumption that a color buffer always exists.

However, since one of the possible likely uses of this extnesion is to support depth texture rendering and stencil rendering for shadowing techniques, it seems like requiring an unused "dummy" color buffer in some cases is both inconvenient and a waste of memory.

Therefore, framebuffers do not require color attachments to be valid. Perhaps though we should require that a framebuffer with *no* attachments is invalid.

It also should be stated that attempting to render without the "appropriate" buffers attached needs to be defined. For instance, presumably, for depth rendering with no depth buffer attached, the depth test is disabled, as it is in traditional GL.

*(46) In the framebuffer completeness criteria, this extension introduces the idea that rendering can fail for implementation dependent reasons. Framebuffer completeness also considers implementation *independent* reasons for failure.*

Do we need to make special distinction between the cases where a framebuffer is not complete because of implementation dependent or because of implementation indepenent reasons?

RESOLUTION: resolved, yes, though this is really tied into how we resolve the minimum requirements for supporting this extension. See issue (61)

Examples where a framebuffer may be incomplete on some implementations but not others include:

- 16 bit z-buffer used with 8 bit stencil buffer
- 32 bit color buffer with 16 bit depth buffer
- others?

Examples where framebuffer MUST be incomplete on all implementations include:

- color-renderable image attached to a non-color attachment point

- depth-renderable image attached to a non-depth attachment point

- stencil-renderable image attached to a non-stencil attachment point

- all images attached to a framebuffer do not have the same dimensions

- multiple render targets of different bit depths

- texture image attached to the framebuffer is part of a currently bound and enabled texture and the image is within the range of mipmap levels that can be fetched by rendering.

To make this determination we need to describe the criteria we should use to determine whether a framebuffer *can* or *must* be incomplete.

The arguments for putting state vectors into the "can" fail case is that a later extension can come along and simply relax those portions of the framebuffer completeness definiton with no additional API. State vectors classified as "must" fail cases would at least require the later extension to add an additional enable to start passing.

(47) Certain state-modification operations can cause a change to the validated state of a framebufffer. (I.e., can make a framebuffer that was complete become incomplete, or vice-versa). Do we want to list exactly which state-modification routines can cause this to happen? If so what is the list?

RESOLUTION: resolved, the answer is: yes we want to delineate exactly which routines can cause validation state changes.

Currently any routine which changes any of the following state can potentially cause framebuffer completness to change:

```
framebuffer state
state changes to attached objects
currently bound fragment program
texture enable state
```

The list of operations that can cause framebuffer a change to framebuffer completeness are spelled out in section 4.4.4.2.

(48) What information should be returned from CheckFramebufferStatusEXT()?

New RESOLUTION: resolved: 8 possible enum values, see issue (55)

```
Previous RESOLUTION: resolved, return one of three
enumerated values:
    1. GL_FRAMEBUFFER_COMPLETE_EXT
    2. GL_FRAMEBUFFER_UNSUPPORTED_EXT
    3. GL_FRAMEBUFFER_INCOMPLETE_EXT
where the three values mean the following:
    1. framebuffer is complete and supported
    2. framebuffer is not supported for implementation
       *dependent* reason
    3. framebuffer is incomplete for    implementation
       *independent* reason

We considered the following two sets of enums:
    Set 1:
        GL_FRAMEBUFFER_COMPLETE_EXT
        GL_FRAMEBUFFER_NOT_COMPLETE_EXT
        GL_FRAMEBUFFER_NOT_SUPPORTED_EXT

    Set 2:
        GL_FRAMEBUFFER_COMPLETE_EXT
        GL_FRAMEBUFFER_INCOMPLETE_EXT
        GL_FRAMEBUFFER_UNSUPPORTED_EXT

New resolution is Set 2.

NOTE: In order to fully resolve issue (55), we expanded this set
of enums to identify all of the implementation-independent
causes for a failure of the framebuffer completeness test.

Originally, we had decided to have a query where the
query returns one of three possible values

One possible set of names that could be returned included:
    FRAMEBUFFER_COMPLETE, and
    FRAMEBUFFER_HW_DEPENDENT, and
    FRAMEBUFFER_HW_INDEPENDENT

How much information we return from CheckFramebufferStatus
is a function of how we expect the return value to be used.
A framebuffer object that is not complete for implementation
*indepednent* reasons is really an indication of a
programming error (like mismatched sizes) and should only
occur during development phase of an application.  The
correct response to this failure is to modify the
application to fix the bug.  After application development,
a framebuffer object that is not complete for implementation
*dependent* reasons is possible.  However, it's not yet
clear whether we can easily characterize these reasons for
failure in a programmatic fashion that would really offer
the application enough information to do something different
at runtime.  Perhaps a human readable info log, intended
just as an application debugging aid, would be more
appropriate.

We also considered whether we needed two separate queries:
One that queried whether the framebuffer was complete
according to the spec, and one that queried whether the
```

framebuffer was supported. This was a little problematic as it might not be possible to answer the "IsFramebufferSupported" query until the framebuffer was complete. A possible solution would have been to return UNKNOWN from the "IsFramebufferSupported" query until the "IsFramebufferComplete" query returned TRUE.

In any event, we decided a single query was a simpler solution.

In addition, the proposed "format group / format restriction" API (see issue 12) should make the implementation-dependent framebuffer incomplete case much less likely (and perhaps impossible) to occur.

Note that if a framebuffer's state violates more than one of the framebuffer completeness rules described in section 4.4.4.2, then it is undefined which of the enumerated value corresponding to one of the violated rules will be returned by CheckFramebufferStatusEXT. Since the initial state of a framebuffer violates multiple rules from section 4.4.4.2, it is therefore undefined exactly which value is returned if CheckFramebufferStatusEXT is called while bound to a newly created framebuffer object.

(49) *When this extension is used in conjunction with MRT (multiple render targets), it would naively be possible to create a framebuffer that had different color bit depths/formats for various color attachment points. Should this be allowed?*

RESOLUTION: resolved, no, not in this extension.
A soon to follow extension may add this feature.

This feature could be supported by simply not requiring that all of the FRAMEBUFFER_COLOR_ATTACHMENTn images share the same internal format. We decided against doing so, however.

ARB_draw_buffers and OpenGL-2.0 do not provide any mechanism to support rendering to multiple color buffers of different formats. Consequently, we chose not to extend OpenGL in this manner as part of the EXT_framebuffer_object extension.

Presumably, a future layered extension could easily add this feature. There are some open questions about exactly how this might work. For instance, what should a query of RED_BITS return if the attached color-renderable images have different formats? In any event, we leave the details of rendering to differently formatted MRT for a future extension to define.

(50) *This extension introduces the concept of attaching one GL object (texture, renderbuffer) to another GL object (framebuffer). In many ways this situation is analogous to a previously poorly specified situation where a GL object could be attached to multiple contexts and the issues this raises with deletion and state propogation are similar. Several issues resolutions have been predicated on the assumption that*

as we specify this container/member relationship, the generation of GL errors should never be triggered in one context based on the asychronous actions of another context. Is this a valid premise?

In other words, should we be using the prevention of asynchronously generated GL errors as a design constraint?

RESOLUTION: resolved, no.

We didn't officially decide on this as a design constraint. However, we essentially decided it by proxy. We decided in issue (26) and (66) that an incomplete framebuffer can cause GL errors on rendering or reading the framebuffer. Consequently, this means a framebuffer shared by two contexts can be made incomplete by either context, and therefore each context can effectively cause the other context to start generating errors asynchronously.

We would expect that the state of framebuffer completness, like all the state of all shared objects, is not "guaranteed" to show up in another context until that context makes an "atomic" request to the server (like a BindFramebuffer for instance). Until that point, it is undefined whether the state change will show up in the other context, just like any state change made on a shared texture object.

(51) What api should we use to query the attachments of the currently bound framebuffer?

RESOLUTION: resolved, (b)

This is an issue because the relevant state for a specific attachment point is a function of the type of object attached to that that attachment point. The attachment point state needs to select a an image from an object which may have a collection of images, for instance the faces of a cube map texture.

This introduces a kind of "polymorphism" into the framebuffer attachment point that is problematic for queries.

We have a few options:

a) Some kind of single atomic query that returns a variable number of values in an array:

```
   GetFramebufferParameteriv(enum target,
                             enum pname,
                             int* params);
        where
        <target> = a framebuffer target
        <pname> = {attachment_point}
```

```
                Upon success "params" will contain an array of
                values where

                params[0] = {NONE | TEXTURE | RENDERBUFFER}

                if params[0] == TEXTURE then
                    params[1] = texture object name
                    params[2] = level
                    params[3] = face
                    params[4] = image
                else if params[0] = RENDERBUFFER then
                    params[1] = renderbuffer name

                Elements of the params array not explicitly defined
                above will have undefined values.

           One problem with (a) is that we would potentially also
           need a query to identify how many state variables will
           come back in this query.  Consider the case where in the
           future we add a new attachable object type that needs
           more selections tate or even add new selection state to
           existing object types.  Applications coded to expect a
           maximum of n values returned today may break in the
           future unless they have a way to dynamically learn how
           many attachment state params will come back from the
           query.

        b) individual queries for all the possible attachment
           state values.

           We create a new routine to add a new <attachment>
           argument, otherwise we'd have an explosion of
           permutations of attachment points and possible attachment
           selection state values

           This could look like

           void GetFramebufferAttachmentParameteriv(enum target,
                                                    enum attachment,
                                                    enum pname,
                                                    int *param);

                where
                <target> = a framebuffer target
                <attachment> = {attachment_point}
                <pname> = one of
                    FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT
                    FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT
                    FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT
                    FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE_EXT
                    FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET_EXT

                Upon success, param will be filled out as follows:

                if pname is FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT,
                then param will contain one of:
                    { NONE | TEXTURE | RENDERBUFFER },
                else if pname is
                FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT, and
                FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT = TEXTURE,
                then param will contain:
                    { name of attached texture }

                else if pname is
                FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT, and
                FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT =
                RENDERBUFFER, then param will contain:
                    { renderbuffer object name }

                else if pname is
                FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL_EXT, and
                FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT = TEXTURE,
                then param will contain:
                    { selected mipmap level of attached texture }

                else if pname is
                FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE_EXT,
                and FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT =
                TEXTURE, then param will contain:
                    { selected face of attached cube map texture }
                    { 0 if texture target is not TEXTURE_CUBE_MAP }

                else if pname is
                FRAMEBUFFER_ATTACHMENT_TEXTURE_ZOFFSET_EXT, and
                FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT = TEXTURE,
                then param will contain:
                    { selected z-slice/image of attached 3D texture }
                    { 0 if texture is not 3-dimensional }

                otherwise, param will contain the value 0.
```

One problem with option (b) is that it is a little heavy-handed as every piece of state needs its own query and enum

Given the above choices, and the problems of extending option (a) in the future, (b) is probably the better of the two choices. It really only adds a few enums, and though it does require an independent function call to obtain each piece of state, this is well-precedented behavior throughout GL.

(52) Should manual mimpap generation via GenerateMipmap apply to textures regardless of whether they are attached to framebuffer objects? Should automatic mimpap generation apply to all textures regardless of whether they are attached to framebuffer objects?

RESOLUTION: resolved, (a) - both apply to both.

This is an issue because the introduction of GenerateMipmap is intended both to address long standing complaints about the existing "automatic" mipmap generation API and to provide a

```
        clear trigger for render to texture API's to know when to do
        the mipmap generation.

        These API's could be considered completely orthogonally.  It's
        clear how they could interoperate.  The question is should they
        interoperate, or should one supercede the other?

        There are a couple of ways to address this issue:

           a) "automatic" mipmap generation applies always and is
               triggered by any gl{Copy}Tex{Sub}Image call if
               GENERATE_MIPMAP is set to TRUE.  "Manual" mipmap
               generation applies always and is triggered by a call to
               GenerateMipmaps

           b) "automatic" mipmap generation applies only
              to textures which are not attached to framebuffer
              objects, calls to GenerateMipmap on "unattached" textures
              are ignored.

              "manual" mipmap generation applies only to textures which
              are attached to framebuffer objects, the value of
              GENERATE_MIPMAP for "attached" textures is ignored

          c) Like option (b), but allow GenerateMipmap to
             apply to all textures and only let automatic mipmap
             generation apply to "non-attached" textures.

          d) Create an enable or other piece of state
             to toggle between allowing automatic and allowing manual
             generation.

       We disregarded (d) because it's not clear why an application
       that had the freedom to set this new enable bit wouldn't
       simply just turn off the legacy automatic mimpap generation
       to start with.

       Of the remaining choices, (a) is the most "orthogonal".  The
       intent of adding GenerateMipmap is to provide a cleaner and
       saner interface to mipmap generation that we would encourage
       developers to use over the automatic method.  Given that, it
       seems like restricting the "manual" generation to certain
       cases doesn't serve that goal, so we wish to allow its use
       on any textures, attached or not.
```

(53) When supporting ARB_draw_buffers, do we need the level of indirection between fragment color outputs and attached mages provided in that API?

```
           RESOLUTION: yes

           ARB_draw_buffers allows the user to set up an "indirection
           table" between the fragment color outputs ("result.color[n]"
           in ARB_fragment_program, and "gl_FragData[n]" in GLSL) and
           the attached draw buffers (FRONT, BACK, LEFT, RIGHT, etc).

           Since EXT_framebuffer_object is creating new non-visible
```

```
            framebuffer objects for which the legacy attachment points
            may not be appropriate, we could consider naming the
            attachment points by numerical index (COLOR0 ... COLORn) in
            which case we could consider dropping this level of
            indirection and allowing the fragment shader to output
            directly into the numerically specified COLOR0 attachment
            point with no indirection.

            However, this indirection is deemed to be useful becaues it
            allows the application to redirect the fragment color
            outputs without changing either the fragment shader itself
            or the current framebuffer attachments, both of which are
            believed to be heavier-weight state change operations than
            simply changing the indirection table via glDrawBuffers..

            Therefore, we elect to retain this level of indirection.
            This leaves open the question of what to call the attachment
            points.  See issue (54).
```

(54) What should we name the logical buffer attachment points, bearing in mind the relationship to ARB_draw_buffers?

```
            RESOLUTION: resolved, option (E), which is a modified
            version of (C).  Specifically, we use the names
            COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT,
            DEPTH_ATTACHMENT_EXT, and STENCIL_ATTACHMENT_EXT (and any
            future attachment points also get the ATTACHMENT suffix).

            The reason this is an issue is that prior to
            EXT_framebuffer_object, the names of the various color
            logical buffer "attachment points" were heavily influenced
            by their intended usage in a graphical window-system.
            Logical buffers for BACK and FRONT_LEFT make sense in the
            context of double buffering and stereo presentation, but
            their use in off-screen rendering situations is
            anachronistic at best and perhaps even confusing.

            There are several options:

            Option (A): stick with the "legacy" names

                This would have us use all of the legacy names which are
                used to identify a single buffer: FRONT_LEFT,
                FRONT_RIGHT, BACK_LEFT, BACK_RIGHT, and AUX0..AUXn.

                This option would require no change to DrawBuffersARB().

            Option (B): AUXn names

                If we wish to avoid using the legacy names, one option
                is to re-use another numerically named set of color
                buffers, the AUX buffers, and only allow framebuffer
                objects to support AUX0..AUXn attachment points.

                This has the advantage of being easy to specify, and
                numerically delimit, but is a little strange as
                framebuffer objects could conceivably support the same
```

```
        number of AUX buffers as the implementation supports
        multiple render targets.  This would have the awkward
        consequence of allowing framebuffer objects to support
        more AUX buffers than the default framebuffer could
        support via the pixel format selection mechanism.

        This option would require no specific change to
        DrawBuffers but might require non-default framebuffers
        to support more AUX buffers than the default framebuffer
        controlled by the window-system pixel format.

    Option (C): COLORn names

        Another option is to rename the color buffer attachment
        points for application-created framebuffer objects to
        COLOR0..COLORn.  This has the advantage of avoiding the
        legacy window-centric names, and avoiding the confusion
        with AUX buffers.  When considered in conjunction with
        the decision in issue (53) to support a level of
        indirection when using ARB_draw_buffers, however, the
        user of the names COLOR0..COLORn may be confusing.  For
        instance, if an ARB fragment program contains color
        output to "result.color[3]", it will not necessarily
        output to COLOR3.  It will actually write to the buffer
        specified by DrawBuffersARB for DRAW_BUFFER3 which may
        or may not be COLOR3.

        This option would require an update to DrawBuffers to
        accept the new COLOR0..COLORn values as valid draw
        buffers and would require a change to DrawBuffers to
        disallow the "legacy" names.  Or at the very least we
        would need some language to describe what happens if the
        DrawBuffers are using the legacy names when the
        currently bound framebuffer is not the default window
        system framebuffer.

    Option (D): DATAn names

        Yet another option is to call these attachment points
        DATA0..DATAn.  This is the same as option (C) but uses
        the word DATA instead of COLOR.  This has the advantage
        of avoiding the above problems with COLOR0..COLORN, but
        introduces a similar conflict with GLSL which uses the
        "gl_FragData[n]" name for its output.  Additionally,
        since we only support multiple render targets for color
        logical buffers, it may be that using the word DATA is
        considered too abstract/general.

    Option (E): add ATTACHMENT to *ALL* names

        In order to avoid the confusion of option (C) and (D),
        we can choose to be more verbose.  We can add the word
        _ATTACHMENT to distinguish these enums from the color
        outputs of a fragment program or fragment shader.  For
        symmetry we also add _ATTACHMENT to the DEPTH and
        STENCIL (and any other to-be-added) attachment points.
```

Similar to (C) and (D), this option requires an update to DrawBuffers to at least accept the new enum values. We could choose to make it illegal to specify the legacy values for non-default framebuffers as well. This is essentially covered by issue (55).

Here is an pseudo-code example using option (E):

```
// Assume presence of color renderbuffers
// with names 1000, 2000, 3000, 4000

GLuint db[4] =
    { COLOR_ATTACHMENT4, COLOR_ATTACHMENT7,
      COLOR_ATTACHMENT1, COLOR_ATTACHMENT2 };

glDrawBuffers(4, db);

glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,   COLOR_ATTACHMENT4,
                             GL_RENDERBUFFER_EXT, 1000);

glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,   COLOR_ATTACHMENT7,
                             GL_RENDERBUFFER_EXT, 2000);

glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,   COLOR_ATTACHMENT1,
                             GL_RENDERBUFFER_EXT, 3000);

glFramebufferRenderbufferEXT(GL_FRAMEBUFFER_EXT,   COLOR_ATTACHMENT2,
                             GL_RENDERBUFFER_EXT, 4000);

Then in ARB_fragment_program
    result.color[0] writes to COLOR_ATTACHMENT4  (i.e., renderbuffer 1000)
    result.color[1] writes to COLOR_ATTACHMENT7  (i.e., renderbuffer 2000)
    result.color[2] writes to COLOR_ATTACHMENT1  (i.e., renderbuffer 3000)
    result.color[3] writes to COLOR_ATTACHMENT2  (i.e., renderbuffer 4000)

And in ARB_fragment_shader
    gl_FragData[0]  writes to COLOR_ATTACHMENT4  (i.e., renderbuffer 1000)
    gl_FragData[1]  writes to COLOR_ATTACHMENT7  (i.e., renderbuffer 2000)
    gl_FragData[2]  writes to COLOR_ATTACHMENT1  (i.e., renderbuffer 3000)
    gl_FragData[3]  writes to COLOR_ATTACHMENT2  (i.e., renderbuffer 4000)
```

See also issue (57) for discussion on querying the number of available color buffers.

(55) What should happen if the current DRAW_BUFFER(s) point to a non-existent logical buffer? Likewise for READ_BUFFER.

RESOLUTION: resolved

partial resolution #1: DrawBuffer(s)/ReadBuffer throws an error if the buffer does not "exist" for all framebuffers (default and non-default).

Should it be an error to call drawBuffer on a non-default framebuffer if named buffer does not exist?

Resolved: yes

partial resolution #2: The test for having a valid draw and read buffer should be part of framebuffer completeness test.

```
            Should be part of completeness test and should all 5
            indpenent reasons add 5 enums?

                Resolved: yes

        partial resolution #3: we should create an enum for
        each implementation independent reason for failing
        the framebuffer completeness test of section 4.4.4.1

            Current names (could change...)
                FRAMEBUFFER_COMPLETE_EXT
                FRAMEBUFFER_INCOMPLETE_ATTACHMENTS_EXT
                FRAMEBUFFER_INCOMPLETE_IMAGES_EXT
                FRAMEBUFFER_INCOMPLETE_DIMENSIONS_EXT
                FRAMEBUFFER_INCOMPLETE_FORMATS_EXT
                FRAMEBUFFER_INCOMPLETE_DRAW_BUFFER_EXT
                FRAMEBUFFER_INCOMPLETE_READ_BUFFER_EXT
                FRAMEBUFFER_UNSUPPORTED_EXT

                NOTE: as per resolution of issue (78)
                FRAMEBUFFER_INCOMPLETE_ATTACHMENTS_EXT
                became
                FRAMEBUFFER_INCOMPLETE_ATTACHMENT_EXT
                and
                FRAMEBUFFER_INCOMPLETE_IMAGES_EXT
                was dropped.
```

This issue is intertwined with issue (56), which discusses whether the DRAW_BUFFER and READ_BUFFER are context or framebuffer object state.

First, some background: If DRAW_BUFFER state is part of the context state vector rather than the framebuffer object state vector (see issue 56), then there are three ways to cause DRAW_BUFFER to reference a color buffer attachment point that "does not exist" in the currently bound framebuffer. If DRAW_BUFFER is part of the framebuffer object state vector, then (A) still applies but (B) and (C) do not.

A) The first case is by detaching, from the currently bound framebuffer object, the image that is attached to attachment point named by the value of DRAW_BUFFER. If an image is attached to COLOR_ATTACHMENTn_EXT in the current framebuffer object and DRAW_BUFFER is set to COLOR_ATTACHMENTn_EXT, and then the application detaches the image from COLOR_ATTACHMENTn_EXT, then DRAW_BUFFER will end up specifying a buffer that "does not exist" in the currently bound framebuffer object.

   There is no analogue to this case in OpenGL prior to EXT_framebuffer_object. Before this extension, the pixel format or fbconfig of a window or pbuffer is immutable once one of these drawables has been created. By design, framebuffer objects (which essentially represent a new type of drawable) have mutable "pixel formats".

B) The second case is by binding between two user-created framebuffer objects, where the two framebuffer objects do not have images attached to the same set of color attachment points. If an image is attached to COLOR_ATTACHMENTn_EXT in the current framebuffer object and DRAW_BUFFER is set to COLOR_ATTACHMENTn_EXT, and then the user binds to a new framebuffer for which there is no image attached to COLOR_ATTACHMENTn_EXT, then DRAW_BUFFER will end up specifying a buffer that "does not exist" in the newly bound framebuffer object.

This is morally equivalent to calling MakeCurrent to bind a context to a different drawable (window or pbuffer) which does not have bitplanes for the color buffer named by the context's value of DRAW_BUFFER. For example, MakeCurrent to a double-buffered window, set DRAW_BUFFER to BACK, then MakeCurrent to a single-buffered window.

C) The third case is by binding between the default framebuffer and a user-created framebuffer object. The attachment points of a user-created framebuffer object are named COLOR_ATTACHMENTn_EXT, DEPTH_ATTACHMENT_EXT, STENCIL_ATTACHMENT_EXT, etc. These are also the legal values of DRAW_BUFFER when a user-created framebuffer object is bound. The default framebuffer, on the other hand, does not use the _ATTACHMENT names but instead uses names such as FRONT_LEFT, BACK_RIGHT, and AUXn as legal DRAW_BUFFER values. Because the two sets of names do not overlap, no value of DRAW_BUFFER is valid for both the default framebuffer and a user-created framebuffer object.

This is somewhat equivalent to case (B), except that in case (C) there is a guarantee that DRAW_BUFFER will become invalid, whereas in case (B) it is only _possible_ that DRAW_BUFFER will become invalid.

The very problem of invalid DRAW and READ buffers was already a feature of OpenGL (and the window-system APIs) before the introduction of the EXT_framebuffer_object extension. The GLX specification specifically addresses what happens when MakeCurrent is used to bind a context to a different drawable (window or pbuffer) which does not possess one of the color buffers referenced by the context's current values of DRAW_BUFFER and READ_BUFFER. GLX addresses this by saying that no GL error is generated, but invalid DRAW_BUFFER behaves as if DRAW_BUFFER were NONE, and reads produce undefined results when READ_BUFFER is invalid.

Now, back to the question of how EXT_framebuffer_object should handle the situation when a framebuffer object is bound and DRAW_BUFFER or READ_BUFFER is not valid while bound to a user-created framebuffer object.

Obviously one option is to resolve the issue the same way is handled by MakeCurrent in the GLX spec. Invalid DRAW_BUFFER acts as if DRAW_BUFFER were NONE, and invalid READ_BUFFER causes read operations to generate undefined results.

A second option is to modify the framebuffer completeness test to fail if the current DRAW_BUFFER or READ_BUFFER reference an attachment point to which no image is attached. This solution would also result in no rendering being performed, but would also generate a GL error when rendering is attempted while in this state, as determined by issue (64). When rendering to a framebuffer object, invalid DRAW_BUFFER would cause generation of GL errors; but when rendering to a window, invalid DRAW_BUFFER would not cause generation of GL errors.

Consider also that, because of the resolution of issue (66), depending on how issue (56) is decided, failing the framebuffer completeness test due to a "non-existent" DRAW_BUFFER or READ_BUFFER may not be a viable option, because the framebuffer completeness test is not allowed to examine context state.

Additionally, there are two sub-issues that fall out of this issue:

    sub-issue 1: Error at DrawBuffer call time or not?
    sub-issue 2: DRAW_BUFFER in or out of completeness test?

[sub-issue 1]: First, what should be the behavior of DrawBuffer(s) and ReadBuffer if the specified buffer does not exist at the time DrawBuffer(s) or ReadBuffer is called?

For default framebuffer (window-system drawables), an error is currently thrown. We can not (or do not wish to) change this legacy behavior of window-system supplied drawables. Consequently, we must resolve several questions here:

For instance:

- Should we do the same thing (error at DrawBuffer time) for user framebuffer objects?

- Is this decision influenced by the fact that user-created framebuffer objects can change their attachments one buffer at a time while window-system supplied drawables can not (i.e., must change all attachments atomically)?

- Also, on other places in this API, such as assembling a framebuffer from framebuffer-attachable images, we have allowed the system to move through "invalid" states without generating an error as long as the system was back in a "valid" state by rendering time (or "validation" time). Should we adhere to that principle here, or is this case different somehow?

- Do we wish to retain the legacy window-system DrawBuffer(s) behavior for application-created framebuffer objects for the sake of maintaining consistency? i.e., Does the benefit of treating default and non-default framebuffers consistently outweigh the earlier decision to delay validation of "invalid" states?

- Both resolutions are examples of "state combination" errors where an error may or may not be generated depending on the order state-changing function calls are made. For instance, in the legacy behavior DrawBuffers does or does not throw an error on user framebuffer objects depending on when you call DrawBuffer relative to when you made your image attachments. On the other hand, if we decided to not throw an error at DrawBuffer time for user framebuffer objects, then DrawBuffer does or does not throw an error depending on whether one is bound to a default or non-default framebuffer. Is one of these "state combination" errors better or worse than the other?

[sub-issue 2]: Should having a DRAW_BUFFER that names a non-existent buffer cause the framebuffer completeness test to fail?

Since image attachments can be changed after DrawBuffer(s) is called, even if we throw an error at Drawbuffer(s) time, we still must decide how to handle having an invalid DRAW_BUFFER at render (or "validation") time. Our options include failing the completeness test, (thus disabling rendering and generating an error at render time) or just behaving as if DRAW_BUFFER is NONE (thus disabling rendering but generating no error at render time).

If the answer is "fail completeness test", then since currently framebuffer completeness can only be affected by framebuffer state, then one of two things has to happen: Either the drawbuffer state must be framebuffer object state, or we have to revisit our decision that framebuffer completeness is solely a property of the framebuffer state and can not be affected by "per context" state.

If the answer is "do not fail completeness test", then the practical consequence of this decision is that having an invalid DRAW_BUFFER behaves as if DRAW_BUFFER is NONE, and no error is generated at render time. Also, in this case, DRAW-BUFFER state can be either per-context or per-framebuffer object state without violating any previously decided issues.

(56) Should the value of DRAW_BUFFER, the corresponding draw buffers indirection table for ARB_draw_buffers, and the value of READ_BUFFER, be part of the context state vector or part of the the framebuffer object state vector?

RESOLUTION: resolved, per-framebuffer object

This issue is intertwined with issue (55), which discusses what happens when the DRAW_BUFFER or READ_BUFFER references a color buffer that "does not exist" in the current framebuffer.

Please first read the "First, some background" section of issue (55), which could be, but is not, replicated here. Note that depending on how issue (56) is decided, cases (B) and (C) from issue (55) might become moot. Specifically, if the DRAW_BUFFER and READ_BUFFER state are added to the framebuffer object state vector, then neither case (B) nor case (C) remains relevant. Only case (A) would continue to be an issue.

The discussion over this issue centered around the following areas:

i) There must be a unique per-context value of DRAW_BUFFER for the default window-system-provided framebuffer.

In GL, before EXT_framebuffer_object, the DRAW_BUFFER was considered context state because:

1) When two contexts are rendering to the same drawable, each context can use a different value of DRAW_BUFFER.

2) When MakeCurrent alternately binds a single context to each of two different drawables, after MakeCurrent DRAW_BUFFER retains the value it had immediately before calling MakeCurrent. This is true even if the last time the context was bound to a given drawable, DRAW_BUFFER had a different value than it does when that drawable is next bound to the context.

Therefore, a per-context value of DRAW_BUFFER must exist, and must be in effect when the FRAMEBUFFER_BINDING_EXT is zero.

Two ways of satisfying this requirement that we have considered include:

A) DRAW_BUFFER is part of the context state vector, but is not part of the framebuffer object state vector.

B) Every framebuffer, including the per-context default window-system-provided framebuffer, has its own value for DRAW_BUFFER.

ii) MakeCurrent vs. BindFramebuffer

As described above, the context state vector must contain a value for DRAW_BUFFER that applies to the default window-system-provided framebuffer, which is used after a call to BindFramebuffer(0). When MakeCurrent is used to bind the context to a different drawable (window or pbuffer), the context's value of DRAW_BUFFER remains unchanged. In other words, the choice of drawable does not affect the value of DRAW_BUFFER.

An application-created framebuffer object is another type of drawable. When the framebuffer binding is changed via BindFramebuffer, issue (56) speaks to the way in which DRAW_BUFFER is or is not updated. If DRAW_BUFFER is part of the context state vector, then DRAW_BUFFER remains unchanged after calling BindFramebuffer, just like it remains unchanged after calling MakeCurrent. On the other hand, if DRAW_BUFFER is part of the framebuffer object state vector, then after calling BindFramebuffer DRAW_BUFFER may change along with the rest of the per-framebuffer state (i.e., the image attachments).

By defining DRAW_BUFFER as context state, the behavior of BindFramebuffer and MakeCurrent are similar, with respect to their effect on the value of DRAW_BUFFER.

On the other hand, by defining DRAW_BUFFER as framebuffer object state, then BindFramebuffer and MakeCurrent differ in their impact on the value of DRAW_BUFFER.

iii) Multiple contexts and shared framebuffer objects

If DRAW_BUFFER is part of the framebuffer object state vector, then a single value of DRAW_BUFFER, like all of the framebuffer object state, will be shared by any context bound to a given framebuffer object. This can be considered either a feature or a restriction depending on whether or not it is desirable for multiple contexts to be able to share a single the value of DRAW_BUFFER.

Note that WGL_ARB_pbuffer plus WGL_ARB_render_texture API has limitations due to the fact that the texture image selection state is stored in the pbuffer drawable. For example, that API does not support six different contexts (in six different threads) simultaneously rendering to the six faces of a cube map pbuffer. It offers no way to share the images without also sharing the pbuffer, and the pbuffer contains a single set of texture image selection state.

EXT_framebuffer_object differs from ARB_render_texture, however, however, in that EXT_framebuffer_object allows the same images of a texture to be attached to multiple framebuffer objects. Consequently, the above cubemap example can be implemented in EXT_framebuffer_object in one or two ways, depending on the resolution of issue (56):

1) Create six framebuffer objects. Attach a different face of a cubemap texture to each of the six framebuffer objects. Each of the six contexts binds to a unique framebuffer object. Technically, this option is available whether DRAW_BUFFER is context or framebuffer state. However, if it is context state, then there is no reason to create six framebuffer objects since the value of the DRAW_BUFFER will already be unique per context.

2) On the other hand, if DRAW_BUFFER is defined as context state, then a second option is available. Using a single framebuffer object, attach each face of the cube map texture to a different attachment point in the framebuffer object. Each of the six contexts binds to the same framebuffer object, but each context uses a different value of DRAW_BUFFER.

iv) Frequency of DrawBuffer calls:

Whether DRAW_BUFFER is part of context or framebuffer state will have an effect on how often one must call DrawBuffer after modifying framebuffer state.

If DRAW_BUFFER is part of the context state vector, then DRAW_BUFFER is guaranteed to become invalid after calling BindFramebuffer to switch between the default framebuffer and a user-created framebuffer object [i.e., this is case (C) in issue (55)]. DRAW_BUFFER may become invalid after switching between two user-created framebuffer objects if the framebuffer objects do not have images attached to the same set of color attachment points. When DRAW_BUFFER is invalid, it is necessary to call DrawBuffer to set DRAW_BUFFER to a valid value or else rendering is disabled.

If, on the other hand, DRAW_BUFFER is part of the framebuffer object state vector, then it should never be necessary to call DrawBuffer after calling BindFramebuffer. DRAW_BUFFER would only become invalid if an image was detached from the framebuffer, or if MakeCurrent bound the default framebuffer to a drawable with a different set of color buffers. (The latter was possible prior to this extension.)

Note that there are several state-modifying routines that may also need to get called after a framebuffer state change, like Viewport, Scissor, etc. We are not proposing that these other routines be part of framebuffer state. One could think of DrawBuffer as being similar to these other routines which you may also need to call when you bind between framebuffer objects.

On the other hand, some have questioned whether an invalid DRAW_BUFFER is really in the same class of problems as an out-of-bounds viewport or scissor because: 1) an invalid viewport or scissor never generates a GL error, and 2) prior to the EXT_framebuffer_object extension an invalid DRAW_BUFFER would generate INVALID_ENUM inside DrawBuffer.

v) Effect on framebuffer completeness test:

By resolution of issue (66), if the draw buffer is context state, then the fact that the draw buffer names a non-existent buffer can not affect the result of the framebuffer completeness test. Note that this still could be considered a "do not render" case, but would separate from the framebuffer completeness test.

If the draw buffer(s) and read buffer are part of the framebuffer object state then having a draw or read buffer name a non-existent buffer can (if we choose) be part of the framebuffer (in)completeness test.

Note, by resolution of issue (64), failing the framebuffer completeness test causes a GL error to be generated when draw or read operations are attempted. Prior to EXT_framebuffer_object, it was already possible to have an invalid value of DRAW_BUFFER if a call to MakeCurrent bound the context to a drawable that did not contain a color buffer corresponding to the context's value of DRAW_BUFFER. However, no GL error would be generated if DRAW_BUFFER obtained an invalid value through this method.

vi) Draw buffer(s) error behavior:

Prior to the EXT_framebuffer_object extension, it was an error to call DrawBuffer or ReadBuffer with a value that did not correspond to one of the logical color buffers of the currently bound drawable (window or pbuffer). Although it was not possible to set DRAW_BUFFER to an invalid value by calling DrawBuffer, it was actually possible for DRAW_BUFFER to have an invalid value after a call to MakeCurrent, as describe in issue (55).

It has not been decided yet whether EXT_framebuffer_object will relax the requirement that the argument to DrawBuffer references a color buffer that "exists" in the currently drawable.

In working group discussions, there was a perception that such an error during DrawBuffer can be generated only if DRAW_BUFFER is part of the framebuffer object state vector. Then when the default framebuffer (window or pbuffer) is current, the legal values of the argument to DrawBuffer would be determined by the pixel format or fbconfig. When a user-created framebuffer object is current, the legal values of DrawBuffer would either be any of the COLOR_ATTACHMENTn_EXT names or only the names of attachment points to which an image is presently attached.

However, given the precedent set by MakeCurrent and DRAW_BUFFER, it seems reasonable to retain the preexisting requirement that the argument to DrawBuffer names a buffer that "exists" in the current drawable. In other words, there already exists precedent that says it is OK for DrawBuffer to generate an error in all the cases described in the preceeding paragraph, even if DRAW_BUFFER is defined as part of the context state vector.

(57) Should we have a query to define the maximum number of attachable color buffers (to support ARB_draw_buffers)?

RESOLUTION: yes, MAX_COLOR_ATTACHMENTS.

Currently an application can query the GL for the maximum number of supported AUX buffers. An application can also query for MAX_DRAW_BUFFERS_ARB in the ARB_draw_buffers extension. Given that we have named the color logical buffer attachment points, COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT, it seems natural that we should have a query to find the maximum value "n".

One thought was that we might be able to use MAX_DRAW_BUFFERS_ARB to store this value, but that value really describes the maximum number of colors that can be simultaneously output which is not the same thing as the number of buffers which can be attached and then selected among using DrawBuffersARB().

This question is related to issue (54), which covers the names of the user-created framebuffer object color attachment points. Using the names COLOR_ATTACHMENT0_EXT through COLOR_ATTACHMENTn_EXT rather than the legacy color buffer attachment names (FRONT_LEFT et. al.) for user-created framebuffer objects has an advantage that the number of color buffer attachment points could be queried independent of the number of AUX buffers and existence of front/back & left/right color buffers as specified in the pixelformat. The number of available offscreen attachment points really should be independent of the properties of the current drawable's pixelformat, especially since MakeCurrent can bind a context to a drawable with a different pixelformat and thus different set of color buffers.

One implication of this query is that the value of MAX_COLOR_ATTACHMENTS_EXT is possibly still dependent on the context/pixel format but independent of the currently bound framebuffer. In other words, MAX_COLOR_ATTACHMENTS_EXT can not change simply because the user called BindFramebuffer(). Or can it? See issue (62)

*(58) What should we do about rendering to textures with borders?
(besides attempt to fervently wish them out of existence, I mean)*

RESOLUTION: resolved, borders are fully supported

Should we allow rendering to textures with borders at all?
Resolved: yes

If we allow this, can you render to the border pixels?
Resolved: yes

The reason this is an issue is that (a) everyone hates supporting borders, and (b) it's not clear what it means to render to a texture with borders.

To disallow rendering to a texture image with non-zero border size, we could add a test for non-zero border size to the definition framebuffer completeness. This might be preferrable to an error at FramebufferTexture, since the user could always redefine the texture to have borders after attachment, and so the framebuffer completeness test is necessary anyway.

However, since borders do exist today and we are not planning to rip them out of OpenGL everywhere else, we decided to support them. It seemed odd that you could still specify borders via TexImage but not render into the same texture so we leave them supported. Note that it's quite possible that implementations which don't support borders may continue to either not support them or fall to software rasterization.

If someday we decide to disallow borders in general, they will be disallowed from this extension as well.

One additional note: section 3.8.2, page 137, of the OpenGL 1.5 specification, states that {Copy}TexSubImage uses negative offsets to refer to border texels. We choose not to do this because negative window-coordinates are undefined. (NOTE: Are negative window coordinates actually undefined? Or are they just not commonly used in practice?)

(59) Should we support named bit depths for stencil renderbuffers?

RESOLUTION: resolved, yes, choose 4 common formats.

We intend to support using renderbuffers to store stencil data. This means we need to consider what kind of "internal format" request we provide for stencil formatted renderbuffers.

We choose to allow a "named" format request for the internal format. This is essentially equivalent to the named internal format request of the TexImage calls. It is merely a request and the driver will attempt to satisfy it as best as possible but may approximate the requested format with another format. Additionally, this request is subject to the same invariance constraints as the texture internal format requests.

For the initial extension we choose the following four sized internal formats, as well as the base internal format STENCIL_INDEX:

```
    STENCIL_INDEX1_EXT
    STENCIL_INDEX4_EXT
    STENCIL_INDEX8_EXT
    STENCIL_INDEX16_EXT
```

(60) If depth buffer is disabled when a user-created framebuffer object is bound and an image is attached to GL_DEPTH, does the depth buffer factor into framebuffer validity determination or is the depth buffer ignored? Similar for other types of logical buffers.

RESOLUTION: resolved, consider all attached images when determining framebuffer completeness, even if the images are "irrelevant" based on the state of the framebuffer.

The main reason to consider not paying attention to certain images (i.e., ignoring the image attached to the depth buffer when depth test is disabled) would be developer convenience. The developer wouldn't need to explicitly detach a buffer, but could set the state to ignore it (disable depth test, or disable color mask, reset draw buffer, etc).

However, this raises the possibility that by simply changing this other state (depth test, stencil test, color mask, etc) the query for framebuffer completeness could change values. This was deemed undesirable. We'd like to be able to minimize the amount of state changes that can cause the framebuffer completeness query to change.

Another strange effect of ignoring "irrelevant" images when considering framebuffer completeness is that we could get an undesirable interaction between draw buffer and the pixel format for the framebuffer. A framebuffer is considered incomplete if the color buffers do not all have the same internal format. But, consider the following case:

- an application attaches a floating point color-renderable image to COLOR_ATTACHMENT1, and

- the application attaches a fixed point color-renderable image to COLOR_ATTACHMENT2 and

- the application sets the DRAW_BUFFER to COLOR_ATTACHMENT1, then

If we ignored the attached images not pointed to by DRAW_BUFFER(s} when evalutating framebuffer completeness, we could consider this framebuffer complete. This framebuffer would use floating point rendering. Now, if the application simply changes the DRAW_BUFFER to COLOR-ATTACHMENT2, then we would also say the framebuffer is complete but now the framebuffer would be using fixed point rendering. We didn't want to allow a change to DRAW_BUFFER to effectively change the pixel format. On the other hand if we always considered all attached images, then in this case described above, the framebuffer would always be incomplete while the formats of the color-renderable images were inconsistent.

To avoid the above complications, we choose to have framebuffer completeness queries consider all attached buffers, regardless of whether they would be "used" according to the current state vector or not.

(61) What are the "minimum requirements" to support this extension?

RESOLUTION: resolved, language added to end of 4.4.4.2

For instance, is it a requirement that there must be at least one renderable color, depth, and stencil format that can all work together? is it a requirement that you must be able to render to *any* "color-renderable" texture format?

Since this extension specifically pulling in functionality that used to be in the domain of the window sytem, we would like to use as a starting point for our requrirements, the language from the GLX 1.3 spec, page 15, which lists the minimum requirements langauge for a conformant GLX implementation.

Questions to answer:

- is the GLX spec a good starting point?

- do we want the same requirements as the GLX spec?

- do we want stronger requirements than the GLX spec?

- do we want some kind of requirement that states that to support this extension, there must be at least one "gl conformant" framebuffer configuration that can be constructed on a given implementation? If so, how do we phrase this?

Anyway, the GLX spec states:

"Servers are required to export at least one GLXFBConfig that supports RGBA rendering to windows and passes OpenGL conformance (i.e., the GLX RENDER TYPE attribute must have the GLX RGBA BIT set, the GLX DRAWABLE TYPE attribute must have the GLX WINDOW BIT set and the GLX CONFIG CAVEAT attribute must not be set to GLX NON CONFORMANT CONFIG). This GLXFBConfig must have at least one color buffer, a stencil buffer of at least 1 bit, a depth buffer of at least 12 bits, and an accumulation buffer; auxiliary buffers are optional, and the alpha

    buffer may have 0 bits. The color buffer size for this
    GLXFBConfig must be as large as that of the deepest
    TrueColor, DirectColor, PseudoColor, or StaticColor
    visual supported on framebuffer level zero (the main
    image planes), and this confguration must be available
    on framebuffer level zero."

So if we did a direct translation of these requirements into our spec, we'd end up with something approximately like the following:

    Although GL defines a wide variety of internal formats
    for textures and renderbuffers, some implementations may
    not support particular combinations of internal formats
    for the images attached to the framebuffer. For a
    framebuffer with these unsupported combinations of
    internal formats, calls to CheckFramebufferStatusEXT()
    will return FRAMEBUFFER_UNSUPPORTED_EXT.

    There must exist, however, at least one combinations of
    internal formats for the images attached to the
    framebuffer for which CheckFramebufferStatusEXT() will
    not return FRAMEBUFFER_UNSUPPORTED_EXT.

    Specifically, implementations are required to support at
    least one set of internal formats for the images
    attached to a framebuffer such that

        - the image attached to the color buffer supports
          RGBA rendering, and

        - the image attached to the color buffer has at
          least as many bits as the deepest visual supported
          by the window-system, although the alpha buffer
          can have 0 bits, and

        - the image attached to the depth buffer has at
          least 12 bits, and

        - the image attached to the stencil buffer has at
          least 1 bit, and

        - rendering to this framebuffer passes OpenGL
          conformance."

However, it looks like no one is seriously using the NON_CONFORMANT_CONFIG bit under GLX or AGL, and on WGL, there is no such bit, so we'd like to "assume" conformance and drop the last clause. Additionally, we'd like to just piggy back on the existing requirements without duplicating them here so we will simplify this language to leave out the last paragraph and list of clauses altogether.

We do wish to retain the notion that there must be some configuration for which FRAMEBUFFER_UNSUPPORTED_EXT is not returned.

(62) Exactly which, if any, queriable state can change after a call to BindFramebuffer and/or a change in framebuffer attachments?

RESOLUTION: resolved, at the Sept. 2004 ARB meeting we resolved in principle that there is a small subset of "framebuffer-related" state that can change. We just need to define exactly the subset. The current subset as listed in section 4.4.5 is below:

```
AUX_BUFFERS
MAX_DRAW_BUFFERS
MAX_COLOR_ATTACHMENTS
RGBA_MODE
INDEX_MODE
DOUBLEBUFFER
STEREO
SAMPLE_BUFFERS
SAMPLES
{RED|GREEN|BLUE|ALPHA}_BITS
DEPTH_BITS
STENCIL_BITS
ACCUM_{RED|GREEN|BLUE|ALPHA}_BITS
```

The reason this is an issue is that traditionally there are some GL context state queries that are dependent on pixel format and window-system state. For instance, doing a GetIntegerv of DEPTH_BITS returns the bit depth of the window-system allocated depth buffer which is a function of the pixel format. If DEPTH_BITS is zero, this means that no depth buffer was present in the pixel format. Other context state queries like MAX_DRAW_BUFFERS, MAX_ACCUM_BUFFERS, SAMPLES, etc are all possibly functions of the current pixel format, and have traditionally been constant over the lifetime of a given context.

However, this extension specifically subsumes some of the operations and state of the window-system pixel format mechanism. So an obvious question is: what should these queries return for things like DEPTH_BITS and MAX_DRAW_BUFFERS when using a non-default framebuffer object?

If we allow these queries to return a value that is a function of the current framebuffer object, then a consequence is that the values returned by these queries can change after a call to BindFramebuffer and/or a change in the attachments of the currently bound framebuffer object.

This may be desirable: for instance, a user may rightly expect that querying RED_BITS returns the red bits of the currently attached color buffer(s). But is the user also expecting that MAX_DRAW_BUFFERS might change? What about SAMPLES or SAMPLE_BUFFERS? What about MAX_COLOR_ATTACHMENTS?

Consider that in developing ARB_draw_buffers it was stated that some implementations might want to set MAX_DRAW_BUFFERS to 1 for pixel formats that also supported multisampling. This would allow implementations to control which capabilities they exported. What facilities do we have for this in this extension - can MAX_DRAW_BUFFERS change if we supported multisampling on a non-default framebuffer object?

Fundamentally, all of the state in table 6.28-6.31 of the OpenGL 1.5 spec (the MAX_* queries) can in theory change as the result of the pixel format changing. Since this extension does an effective pixel format change, what if any of this state can/should be allowed to change when framebuffer attachments are changed?

(63) Should we change ValidateFramebuffer into an explicit enum-based query for framebuffer completeness?

RESOLUTION: resolved, separate API function rather than a Get query, to emphasize the "on-demand" state examination.

We did choose a different name for ValidateFramebuffer(). In issue (67) we decided to rename this function CheckFramebufferStatus().

For reference the reason this is an issue is that, as originally described, ValidateFramebuffer (now called CheckFramebufferStatus) served three purposes:

First, it forced an "on-demand" examination of the current framebuffer state (including framebuffer attachment state) and the state of the attached images. On some implementations this examination might be expensive, and therefore there was a desire to control exactly when the operation would occur.

Second, because of the implementation dependent reasons that a framebuffer might be considered not complete, ValidateFramebuffer served as a query for an application to determine at run-time if a seemingly compatible combination of attached images is actually incompatible on the current GL implementation.

Third, ValidateFramebuffer was more than just a query. It was a function that would set a piece of framebuffer state that "enabled" rendering if the framebuffer was determined to be complete. After certain changes to framebuffer state, or in the initial default state, unless ValidateFramebuffer was called prior to rendering, and unless framebuffer validation "passed", rendering would be disabled.

However, now that it is no longer required to call ValidateFramebuffer prior to rendering, ValidateFramebuffer doesn't really set any state. The third reason is no longer pertinent.

This leaves us with the first and second reasons. The first reason in particular seems to be driven by convenience. It is convenient to be able to control when this operation happens, but it is arguably also convenient to be able to force the examination/validation of a wide variety of other pieces of GL state, yet we don't have specific on-demand "ValidateTexture" or "ValidateBlendState" routines. In addition, on some implementations framebuffer validation may be less expensive than originally thought.

So if we ignore the first reason for a moment, we are left the second reason for ValidateFramebuffer - a query of the framebuffer completeness. We do wish to retain this query somehow, so we could choose to leave it in its current form, or we could choose to make it look like other more traditional queries, i.e., some kind of GetInteger, GetFramebuffer, or GetFramebufferParameter call.

If we feel like the first reason is still valid, we could also choose to retain a ValidateFramebuffer call to get the "on-demand" state examination and still choose to make separate query for the framebuffer completeness.

Either way, if we decide to make an enum-based query we need to choose the form. We could choose to use GetInteger and query for COMPLETENESS. (If we do this, we'd need a "per-target" variant of the enum, i.e., FRAMEBUFFER_COMPLETE, and if a read framebuffer target is added later, READ_FRAMEBUFFER_COMPLETE would need to be added as well.) This would be similar to how texture bindings are queried on a per target basis as in GetIntegerv(TEXTURE_BINDING_2D, &param). Another option is to add a target-aware query routine, i.e., GetFramebufferiv(FRAMEBUFFER, COMPLETE, &param); this is similar to what the ARB vertex/fragment program API's did to query per-target state like PROGRAM_NATIVE_INSTRUCTIONS_ARB.

(64) Should it be a GL error to attempt to render with an incomplete framebuffer?

RESOLUTION: resolved, "YES"

In looking at other GL resources that can be considered "incomplete" for rendering, there were two precedents to draw on here: (a) textures and (b) programs/shaders.

a) For textures, the GL behaves as if the incomplete resource is simply not available. That is, if an application attempts to render with an incomplete texture, then the GL behaves as if texturing is simply disabled. No error is thrown.

b) For ARB_vertex_program and ARB_fragment_program, and GLSL shaders, if a program or shader is invalid, then the GL throws an error at "Begin" time.

Originally, we choose style (a): treat an incomplete framebuffer similar to a "pixel ownership test failure". This means that no fragments are generated, reads of the framebuffer generate undefined pixels, and no error is thrown.

[NOTE: Technically, according to the GL spec, the fate of rendered fragments that fail the pixel ownership test is left up to the window-system and is therefore implementation dependent. A better way to handle this is to mimic make_current_read's language "as if DRAW_BUFFER is NONE"]

However, since the a query of framebuffer completeness can only answer the question "is the framebuffer complete right now?", but doesn't indicate whether the application may have attempted to render with an incomplete framebuffer earlier, we decided to throw an error in this case as an aid to the developer. Throwing an error has an advantage in that the error state is retained, like all GL errors until the user calls GetError().

Another option that was considered was to extend the framebuffer completeness query to indicate that the framebuffer is complete now, but was incomplete during earlier rendering. The downside of this option was that then there would then be two return values for the query that would mean "framebuffer complete right now". So in the end, we simply decided to leverage the existing GetError semantics to capture this "sticky" error behavior.

One additional concern was that gl errors are traditionally only used to indicate programming errors on the part of the application, but the framebuffer completeness test may have failed simply because of implementation dependencies through no fault of the application. We decided to adopt the notion is that it is an error to attempt to render with an incomplete framebuffer, on all implementations, and so it actually *is* a programming error if an application does not attempt to deal with an incomplete framebuffer prior to rendering.

(65) *If it is an error to render to or read from an incomplete framebuffer, should we use INVALID_OPERATION or create a new error?*

RESOLUTION: resolved, INVALID_FRAMEBUFFER_OPERATION_EXT

We resolved to create a new error at the September ARB meeting and then resolved the name of the error within the work group.

> We agreed that if we throw an error here, we'd like a new error enum, particularly because the error may have been triggered by a framebuffer which is incomplete for implementation dependent reasons.

Some options for the new error name which were discussed:

    OPERATION_ON_INCOMPLETE_FRAMEBUFFER
    INCOMPLETE_FRAMEBUFFER
    IMPLEMENTATION_DEPENDENT_FAILURE
    INVALID_FRAMEBUFFER
    INVALID_FRAMEBUFFER_OPERATION

(66) There are several issues related to how we treat DrawBuffer(s) and other context state with respect to framebuffer completeness. We'd like a self-consistent model here and this may affect the resolution of issue (8), (44), (55), and (56).

RESOLUTION: resolved, (d) - no context state in framebuffer completeness test, but context state can affect whether rendering takes place, does not take place, or is undefined. Note option (d) required us to revisit issue (44).

The first question we had to answer was:

> Is it desireable that "framebuffer completeness" be purely a property of the set of framebuffer state (which includes the state of the images attached to the framebuffer)? Or can a framebuffer's completeness depend on "non-framebuffer" context state as well?

For instance, there are currently two pieces of context state that can affect framebuffer completeness: texture binding state and draw buffer state.

First, in issue (44), we decided that attaching an image of a currently bound and enabled texture to a framebuffer can cause a framebuffer to be incomplete. The texture binding is context state and there are pieces of the texture object state (base level, max level) that can also affect the determination of framebuffer completeness. (Additionally if we add render-to-vertex-array functionality later, we might expect to have a framebuffer completeness requirement that examines the state of the currently bound vertex array.)

One way to avoid this context dependency is to revisit issue (44) and say that this "texture-from-destination" case simply generates undefined rendering but does not affect framebuffer completeness. This would replace the "expressly disabled" rendering and framebuffer incompleteness with "undefined rendering", but would also let implementations avoid checking context state during the validation of the framebuffer state.

The second piece of context state that might cause framebuffer validation failures is the draw buffer(s) and/or read buffer state. It has been suggested in issue (55) that if the draw buffers specify attachment points with no attached images, then the framebuffer might be considered incomplete. If we choose to do this, then we would have context state influencing framebuffer completeness state. However, if we resolve issue (56) to say that the draw

```
        buffer state is part of the framebuffer object state, then
        the draw buffer is no longer context state and this
        particular dependency of framebuffer completeness on context
        state goes away.

        The above discussion leaves us with several self-consistent,
        but different sets of decisions:

            (a) Remove context dependencies from framebuffer
                completeness.

                To do this we would:

                - Move draw buffer state from context into
                  framebuffer: issue (56)

                - Make "texture-from-destination" undefined instead
                  of a reason for framebuffer incompleteness: issue
                  (44)

                - Presumably, if we created a render-to-vertex-array
                  extension layered on this one, we would likely
                  also make rendering into the currently bound
                  vertex array undefined as well.

                With option (a), we can say that having draw buffer
                set to an non-existent buffer is a reason for
                framebuffer incompleteness and there are no context
                dependencies.  This would resolve issue (55).

            (b) Allow context dependencies in framebuffer
                completeness.

                Essentially this means that the result of a query of
                framebuffer completeness is dependent on the context
                making the query - or put another way, the
                framebuffer completeness state is context state not
                framebuffer state.

                If we choose this option (b), then we are esentially
                free to resolve issues (44), (55), and (56)
                however we want.  In other words:

                    - draw buffer can be either context or
                      framebuffer state: issue (56)

                    - "texture-from-destination" can be either
                      undefined or a reason for framebuffer
                      incompleteness

                    - draw buffer specifying a non-existent buffer
                      can be a reason for framebuffer incompleteness
                      or could result in undefined behavior: issue
                      (55)
            (c) Remove the framebuffer object and make the
                framebuffer state part of the context.

                This option redefines the issue by not making a
                distinction between framebuffer "object" state and
                "context" state, therefore framebuffer completeness
                depends only on "context" state because all of the
                "framebuffer" state is now "context" state.

                This would mean that there is now a subset of state
                in the context that can be considered the
                "framebuffer state" of the context.  This is the set
                of state that would presumably be pushed/popped
                under a theoretical FRAMEBUFFER_BIT for
                PushAttrib().

                Regardless of whether there is a framebuffer object,
                framebuffer completeness may or may not still depend
                on pieces of other "context" state that are not part
                of subset of context state related to the
                "non-default" framebuffer (for instance, texture
                bindings and/or draw buffer state).

                If we choose this option (c),

                    - we remove the framebuffer object: issue (8)
                      This means:

                        - removing gen/is/bind/delete framebuffer
                          object

                        - moving the attachment state into the
                          context

                        - creating new context bind points for
                          framebuffer attachments and creating new
                          BindFramebufferAttachableImage calls or
                          using the FramebufferTexture() calls to do
                          context binds of framebuffer-attachable
                          images

                    - we decide whether there is a single set of
                      draw/read buffer context state or a 2nd set of
                      draw/read buffer context state to be used for
                      "non-default" framebuffer objects.  Either way
                      it's "context" state but we need to know if we
                      have one set of state or two.  This is a
                      variation on issue (56).

                    - as in option (b), "texture-from-destination"
                      can be either undefined or a reason for
                      framebuffer incompleteness

                    - as in option (b), a draw buffer specifying a
                      non-existent buffer can either be a reason for
                      framebuffer incompleteness or could result in
                      undefined behavior: issue (55)
                    - all the framebuffer attachments become context
                      state

                    - we add a framebuffer enable/disable bit to use
                      to distinguish between the "default" and
                      "non-default" framebuffer

            (d) Create a new category of reasons that you can't use
                a framebuffer for rendering in a specific context,
                but that are not part of the test for "framebuffer
                completeness"

                Essentially, this is a kind of hybrid of options (a)
                and (b).  There are no context dependent reasons for
                framebuffer incompleteness, but at the same time
                there are some additional context-dependent
                constraints on using a framebuffer.  In other words,
                a framebuffer can be complete but still not suitable
                for rendering by a given context.

                This creates two categories of tests that can be
                used to disable rendering - the set of
                context-independent test that are used to determine
                framebuffer completeness, and the set of tests that
                are context-dependent and not used to determine
                framebuffer completeness.

                An open question is: should we add a separate query
                for this second set of context-dependent tests
                and/or a "meta-query" that would cover both sets.
                This "meta-query" would return "true" if and only if
                the framebuffer is complete *and* it can be used in
                this context.

                Note that while the "is framebuffer complete" query
                is required by the fact that a framebuffer can be
                incomplete because of implementation dependent
                reasons, the second query of the context-dependent
                test results and the "meta query" are primarily
                debugging aids, though perhaps convenient ones.

                The framebuffer completeness query is analogous to
                asking if a texture is "mipmap complete".  The
                question, "can I render into my framebuffer", is
                analgous to asking the question, "is texturing
                enabled."  A bound texture may be "complete", but
                texturing can still be disabled due to an
                unfortunate combination of non-texture-object
                context state.  Option (d) is basically saying the
                same thing of framebuffer objects.

                To implement option (d), we'd do the following:

                - If draw buffer is defined as "context state" it
                  can not affect framebuffer completeness, but if
                  draw buffer is defined as framebuffer state it
```

might affect framebuffer completeness. See issues (55) and (56).

- Make "texture-from-destination" undefined instead of a reason for framebuffer incompleteness: issue (44). Technically, this could still be an error unrelated to framebuffer completeness, but we are trying to avoid creating a precedent for arbitrary "errors at begin time". When this case was included in the "framebuffer completeness" validation, the additional cost of generating the error was free. But if this "texture-from-destination" case is not part of framebuffer completeness, then it is an additional cost at begin time to detect this in order to flag an error (and/or disable rendering). To avoid this cost, we would make this undefined.

- Presumably, if we later create a render-to-vertex-array extension layered on this one, we would likely also choose the same resolution for rendering into the currently bound vertex array as we choose for the currently bound texture.

(67) In issue (63) we decided we want to use a dedicated API function to test framebuffer completeness. We might want to change the name of "ValidateFramebuffer" however. If so, what name should we use?

RESOLUTION: resolved, CheckFramebufferStatus()

One reason we decided to retain an explicit API function instead of just using a GetInteger style query is to emphasis the "on-demand" state examination that takes place when making this query.

However, some were uncomfortable with the name ValidateFramebuffer for this purpose. Some felt that it implied a requirement to call the function, and others felt it was too similar in name to the GLSL function ValidateProgram which served a related but slightly different purpose. So we chose a new name.

Some options we considered:

```
    ValidateFramebufferCompleteness()
    CheckFramebufferCompleteness()
    CheckFramebufferStatus()
    IsFramebufferComplete()
```

(68) Exactly which levels should by generated by GenerateMipmapEXT?

RESOLUTION: resolved, from TEXTURE_BASE_LEVEL+1 through q

Automatic mipmap generation via GENERATE_MIPMAP generates from TEXTURE_BASE_LEVEL+1 through p, which is the 1x1 level. However, applications frequently don't want to waste

        computation generating past q, which is the min of
        TEXTURE_MAX_LEVEL and p. The only recourse is to accept the
        performance hit or to not use GENERATE_MIPMAP.

        Arguably GENERATE_MIPMAP should have been specified to
        generate only through q. We have the opportunity to "fix"
        this problem by "correctly" specifying the new function
        GenerateMipmapEXT to generate only from TEXTURE_BASE_LEVEL+1
        through q.

        As the specification of GenerateMipmapEXT is currently
        written, GenerateMipmapEXT only generates levels
        TEXTURE_BASE_LEVEL+1 through q.

(69) What should we call the framebuffer objects to distinguish them from the default framebuffer?

        RESOLUTION: resolved, "application-created"

        Currently we call these "application-created" framebuffers
        Some places in the spec have also referred these as
        "GL-allocated" framebuffers. Whichever term we use, we
        should use it consistently.

        Some terms we considered:

            "application-created" framebuffers
            "application-allocated" framebuffers
            "non-default" framebuffers
            "GL-created" framebuffers
            "GL-allocated" framebuffers
            "dynamically-created" framebuffers
            etc.

        The GL spec already talks about "creating" textures, not
        "allocating" them, so "*-created" seems like a better
        choice.

        It's a bit of a toss-up between "GL-created" and
        "application-created". Technically, the "GL" really creates
        and manages these objects but it only does so at the request
        of the application. Going with "application-created" for
        now.

(70) With which, if any, attribute bit does the framebuffer binding push and pop? The same question applies to the current renderbuffer?

        RESOLUTION: resolved, don't push/pop framebuffer binding
        bit for now. If desired, we may add this in the ARB/core
        update of this spec.

    There are a few precedents to choose from.

    The ARB_vertex/fragment_program extensions chose to *not*
    push/pop the current program object binding. It's not clear if
    this was intentional or which existing attribute bit was

appropriate to use or if there was a desire to not create a new attribute bit.

ARB_vertex_buffer_object buffer objects and GL core texture objects do push/pop the bindings with the existing VERTEX_ARRAY and TEXTURE bits respectively. In addition, the texture enables are push/pop'ed with the TEXTURE bit.

If we do wish to push/pop the FRAMEBUFFER_BINDING_EXT state we probably need a new FRAMEBUFFER bit.

We could also consider adding a RENDERBUFFER_BIT to cover the current renderbuffer binding or allow this renderbuffer binding to push/pop with the FRAMEBUFFER bit. However, it's less clear that push/pop'ing the renderbuffer binding is useful since the renderbuffer binding is not used for rendering. The renderbuffer binding is only used to set the current renderbuffer for renderbuffer storage allocation and queries.

Also, there are a related set of questions about how much state should push/pop with a new FRAMEBUFFER bit. Should we push/pop all of the framebuffer object state in addition to the current binding? Similar to the way vertex array's can be attached to VBO's, use of VBO, framebuffers can be attached to other GL objects. The TEXTURE_BIT covers both per object (min/mag filter) and per context (texture environment and enable) state. It's not clear if this is useful or desirable to have per-object state push/pop. With the addition of object semantics, it seems like the need for push/pop of object state is reduced.

In the end, since we'd need to create a new bit anyway, we decided to defer adding push/pop semantics until we understand the implementation ramifications better. If we decide to create the bit later on in the ARB or Core revision of this extension, we can add it in a backward-compatible fashion.

(71) Should we spell out precisely which rendering and reading routines can cause us to generate an error at the time the rendering or reading functions are called?

RESOLUTION: resolved, keep the same language as ARB vertex/fragment program and GLSL for now, with the addtitions relevant for reading the framebuffer, but recommend the ARB look at this when doing the next core GL spec revision.

Currently GL has a few cases that can cause errors at render time. Specifically, attempting to render with a mapped vertex buffer object, an invalid low-level vertex or fragment program, or an invalid GLSL program object all generate errors at "Begin" time.

This extension adds a new error at "begin" time. Attempting to render with an "incomplete" framebuffer generates INVALID_FRAMEBUFFER_OPERATION_EXT. In addition, this extension adds the same error at "read" time if the application tries to read from an "incomplete" framebuffer.

```
    The ARB vertex program, ARB fragment program, and GLSL extension
    specs state that an app which tries to use an "invalid" object
    can generate errors when Begin, RasterPos, or any command that
    performs an explicit Begin is called.

    This extension has adopted similar language.  So the question
    asked by this issue is: do we need ot be more explicit.

    There are some ambiguities.  For instance, it is an error to
    write pixels using an "implicit Begin" operation like DrawArrays
    if the current vertex program is invalid, but it is not an error
    to do an Accum operation which also writes pixels to the
    framebuffer.

    This issue applies to all of these extensions.

    Options include:

        - listing all routines which can render or read from the
          framebuffer and stating that they can cause an error if
          the framebuffer is incomplete, solving the problem for
          this extension only.

        - adding to the GL core a table of "routines that read
          pixels" and "routines that write pixels" and referencing
          those tables in the language for each of these extensions.

    Because each extension is doing something a little different,
    it's not even clear if the second option is a viable option.
    It's possible each extension would need its own list of routines
    which can generate errors anyway.

    Basically, this is a larger problem than this
    EXT_framebuffer_object extension.  For now, we choose to use the
    same (vague-ish) language adopted by the
    ARB_vertex/fragment_program and GLSL extnesions.

    We do recommend, however, that the ARB address this issue in the
    next GL core revision.
```

(72) *Should the framebuffer completeness test include a clause that says "at least one color attachment" has been made? Or "at least one attachment of any type"? Or is the framebuffer still complete when there are no attachments at all?*

```
        RESOLUTION: resolved, a framebuffer must have at least one
        color-renderable, depth-renderable, or stencil-renderable
        image attached to be complete.

        While a framebuffer with only depth, or only color
        attachments seems plausible, we couldn't come up with a
        sensible use for a framebuffer with no attachments at all,
        so the assumption is that this is an unintended error on the
        part of the application.  Therefore, we choose to make it
        part of the framebuffer completeness test.
```

We could make this its own clause in the framebuffer completeness test. If we choose to do so, we should probably come up with a new FRAMEBUFFER_INCOMPLETE_* to conform to our previous practice of keeping one enum per clause.

However, since this is really related to the attachment state, we could just piggy back this on the first clause and same all the attachment points must be "attachment complete" and there must be at least one color, depth, or stencil buffer attached.

If we choose this latter option, we can continue to use the FRAMEBUFFER_INCOMPLETE_ATTACHMENT enum to cover this case.

(73) *This clause from framebuffer completeness (before it was reworded, see below):*

* The value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT must not be NONE for any color attachment point named by READ_BUFFER.

basically requires at least one color attachment is non-NULL. But this is not what we want. So what should we do?

RESOLUTION: resolved, (4a) READ_BUFFER can be NONE

The reason is: READ_BUFFER is not allowed to be NONE, which in turn means to be framebuffer complete, READ_BUFFER must be COLOR_ATTACHMENTn_EXT for some n which has an image attached. However, we don't wish to preclude a no-color framebuffer. What should we do?

Options include:

4a) Allow READ_BUFFER of NONE, reads of color from the framebuffer when read buffer is none, generate error INVALID_OPERATION

4b) Generate an error when a read operation (ReadPixels, CopyPixels, etc) is attempted while the color attachment point referenced by the READ_BUFFER does not have an attached image.

4c) Reverse earlier decision to allow complete framebuffer not to have any color attachments. Instead, require at least one color attachment. READ_BUFFER must point to a valid color attachment or else the framebuffer object is incomplete.

(4c) seems to require the user attach a color buffer just to be able to read the depth buffer of a depth-only framebuffer.

(4b) seems to suffer from the same problem (unless we move the "valid read buffer" test out of the completeness test).

Of these choices, (4a) seems to be the most palatable. We choose the allow the value of READ_BUFFER to be NONE, but reads of color buffers when READ_BUFFER is NONE will generate an error, in order to be consistent with the decision in issues (26) and (65).

Note: that clause was eventually reworded to say:

* If READ_BUFFER is not NONE, then the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT must not be NONE for the color attachment point named by READ_BUFFER.

(74) What should CheckFramebufferStatusEXT return if FRAMEBUFFER_BINDING_EXT is zero?

Secondary question: what should CheckFramebufferStatusEXT return if there is an error?

RESOLUTION: resolved, default fb returns COMPLETE always, and CheckFramebufferStatusEXT returns FRAMEBUFFER_STATUS_ERROR if there is an error (bad target)

This goes to a larger question of whether all framebuffers including the default window-system-provided framebuffer have a "completeness" state, or if "completeness" is only a property which applies to application-created framebuffers.

For the case where the current FRAMEBUFFER_BINDING_EXT is zero, options include:

- CheckFramebufferStatusEXT returns an error when FRAMEBUFFER_BINDING_EXT is zero.

- CheckFramebufferStatusEXT always returns FRAMEBUFFER_COMPLETE_EXT when FRAMEBUFFER_BINDING_EXT is zero.

For the case CheckFramebufferStatusEXT generates an error, options include:

- reworking CheckFramebufferStatus into a "get" style routine that returns a value (or not) in an input parameter like GetIntegerv

- returning a known value like NONE or 0

- returning undefined results

(75) How are state values for the stencil index write mask and stencil reference value affected by this extension?

RESOLUTION:
a) index write mask is stored as 32 bit value, default is all 1's, and
b) reference value is not clamped on specification but rather is clamped on use and query, and
c) we need to add the stencil reference value

to the state table that lists the state values that might change after a framebuffer state change

The reason this is an issue is that the current GL specification indicates that the stencil index write mask and the stencil reference value are masked/clamped according to the number of stencil bitplanes. However, in this extension the number of stencil bitplanes can now change dynamically as the image attached to the framebuffer is changed.

For instance, if these values are clamped/masked according to the bitdepth of the currently attached stencil buffer, what should happen if the user later attaches a stencil buffer of a different bit depth? Must the stencil reference value or index write mask be respecified?

For the index write mask: we decide to treat this value as "all 1's" as the current specification allows, but further define the number of 1's to be 32 (the minimum width of an integer in GL), and a likely maximum stencil bitdpeth for the forseeable future. This should retain backward compatbility and still handle the case where the bitdepth of the stencil buffer can change dynamically.

For the stencil reference value, we decide to treat this state similar to way various clamped colors are treated in the ARB floating point pixel extensions. Specifically, the state values are clamped against the current logical buffer bitdepths as they are used for rendering and queried, but are not clamped on specification. This means that these state values do not need to be respecified just because the logical buffer bit depth changes, and retains backward compatibility to the behavior prior to this extension.

We will update the appropriate sections of the specification to describe this behavior.

(76) Currently framebuffer objects are shared, should we make them not shared across contexts?

RESOLUTION: yes, framebuffers are shared like display lists and textures are shared.

Initially it was suggested that some complicated multi-context semantics might be avoided if if the namespace for framebuffer objects were not shared across contexts. Specifically, some members of the group felt that by not sharing framebuffer objects, we could avoid the situation where:

a) one context can change the draw buffer of a framebuffer object in use by another context.

b) one context can change the attachments of a framebuffer object which may be in use by another context.

However, after some discussion, we realized that even if we didn't share framebuffer objects, there were still interactions similar to those listed above because the underlying images could still be shared. Consequently, one context could still affect the completeness and attachments of the framebuffers in another context by modifying or deleting the framebuffer-attachable images shared by both contexts.

So in the end, we decided to retain the share-ability of framebuffer objects rather than introduce an asymmetry with other GL objects like textures.

(77) If the application deletes an object and that object contains an image which is attached to a framebuffer object, exactly when and how is the image detached from the framebuffer?

RESOLUTION: resolved, option (1): images are detached from the currently bound framebuffer on delete, but images remain attached to any non-bound framebuffers.

This is issue is somewhat related to the multi-context object-sharing discussion currently going on in the ARB.

This extension presupposes that framebuffer attachments represent a reference to the attached image (or more correctly - a reference to the object containing the attached image). Since having a reference to an object affects when the object (and/or its name) is deleted, object deletion semantics are tied into the notion when the state describing these references is modified. In other words, the semantics of when objects are deleted are affected by the details concerning when a change to the framebuffer attachment state takes place.

Prior to the EXT_framebuffer_object and GLSL extensions, the only way in which an object not currently bound to this GL context could be modified, was when the object was modified by another GL context.

Both the EXT_framebuffer_object and GLSL extensions allow an object (texture, renderbuffer, shader) to be attached to a "container" object (framebuffer, program). With the introduction of "attachment", an object could be bound to the context at more than one binding point. For example, a texture can be bound to TEXTURE_2D_BINDING, and it can also be indirectly bound through the FRAMEBUFFER_BINDING if it is attached to the framebuffer object bound to the FRAMEBUFFER_BINDING.

Furthermore, a texture can be attached (by reference) to a framebuffer object that is not bound to any context, while at the same time the texture *is* bound to context's TEXTURE_2D_BINDING. Because the texture state is a part of the framebuffer object's state, it is now possible for modification of a texture through TEXTURE_2D_BINDING to cause modification of a framebuffer object, even though the framebuffer object is not bound to any context at the time it is modified.

One conceptual model for dealing with this situation is to treat attachment similar to bind, but instead of binding to a context, you are "binding" to another object. For the purposes of managing object references, object lifetimes, state propogation semantics, etc., these attachments can be considered to be "just like" a bind operation. [A "bind" and an "attach" are not exactly equivalent, however; see issue (82) for a further discussion on Bind vs. Attach.]

If we agree on the above conceptual model, then we may wish to look to the multi-context situation for guidance on how to treat state changes to non-currently-bound framebuffer objects.

Unfortunately, the multi-context semantics are poorly defined by OpenGL. If we decide to use them as a guide, we should at least define what they are and this is why the larger ARB is looking at this issue now.

For EXT_framebuffer_object, there are three choices for behavior. In each case, we defer to the larger ARB the details about when an object name is available for reuse. For the purposes of this discussion, we are looking only at state changes governing the attachments. The three choices are listed below:

For the sake of concrete simplicity, this discussion speaks to the images of a texture object; but it applies equally to the image of a renderbuffer object.

If you delete a texture object while one of the texture's images is attached to a framebuffer object (or multiple framebuffer objects), then:

(1) The image is automatically detached from the currently bound framebuffer object only.

If the image is also attached to any other framebuffer objects, then the image is NOT automatically detached from those.

The application is responsible for manually detaching images from the other framebuffer objects, by rebinding each framebuffer in turn and performing an explicit detach operation.

Until the application manually detaches the image from the other framebuffers, those framebuffers continue to use the image for rendering. The other framebuffer objects have a reference to the image until the image has been detached from them. In this way, attachment behaves as if the image was "bound to the framebuffer object".

(2) The image is automatically detached from the currently bound framebuffer object. Also during DeleteTexture, the image is automatically detached from any other framebuffer object to which it is attached; however, the image is not guaranteed to be detached from the other framebuffer objects until the next time those framebuffer objects are bound via BindFramebufferEXT.

Similar to option (1), in order to "really" delete the object, the application is responsible for rebinding all the framebuffer objects to which the deleted image was attached. However, unlike option (1), the application need not actually perform an explicit detach operation. The application can merely bind the framebuffer.

Until the application actually rebinds the framebuffer the images are not actually detached and deleted. The other framebuffer objects continue to hold a reference (like a binding) to the image until the next time the framebuffer objects are bound.

(3) The image is automatically detached from all framebuffers objects during DeleteTextures, including the currently bound framebuffer as well as any other framebuffers to which the image is attached.

The application need not explicitly bind to, and detach the image from, any framebuffer that is not bound at the time DeleteTextures was called.

Because the framebuffer object has a reference to the texture object, and the texture object's state is considered part of the framebuffer object's state, this resolution implies that DeleteTextures may modifiy the state of a framebuffer object that is not the currently bound object.

With reference to the object-sharing discussion that is going on in the ARB right now, for (a)-style implementations, options (2) and (3) are indistinguishable. However, for (b)-style implementations, implementing (3) would require textures to store a list of all attached framebuffers while (2) would not.

Options (2) and (3) essentially treat the currently-bound and non-currently-bound framebuffers the same--i.e., deleting the image (ultimately) detaches it from all framebuffer. This may be desirable as a convenience to the application.

On the other hand, Option (1) treats the currently bound framebuffer special, in that deletions are performed automatically much like textures are unbound automatically from the current context's binding points, but they are not unbound automatically from other contexts' binding points.

Also, Option (1) leaves the application in control of when the images are detached, which also may be desirable.

We choose option (1) because it is the simplest, and it also does not unduly burden implementations regardless of their choice of (a) versus (b) object-sharing model.

If an implementation has the (a)-style object sharing model, then the fact that images remain attached to non-bound objects has no affect on when the object name may be re-used. If the implementation has a (b)-style object-sharing model, then the outstanding attachments will delay re-use of the object name until the image has been detached. Regardless of whether the ARB chooses (a) or (b) behavior, or even if the ARB chooses to leave this behavior undefined, we can "piggy-back" on the name-reuse semantics they decide.

Also, option (1) means that if the application deletes a texture while one of the texture's images is attached to a framebuffer object that is not bound, then the application may continue to render into the image after the framebuffer is bound again, regardless of the (a) vs. (b) choice.

Finally, note that if a context deletes an object containing an image attached to the currently bound framebuffer, then we first detach the image from the bound framebuffer. This means that the state change to the framebuffer (the detach operation) is guaranteed to be picked up by any other context the next time the framebuffer is bound in one of the other contexts.

(78) Should we collapse the notions of "framebuffer-attachable image completeness" and "framebuffer attachment completeness" into a single type of completeness (probably retaining the name "framebuffer attachment completeness"

RESOLUTION: resolved, yes, eliminate "framebuffer-attachable image completeness" and add a "non-zero-area" requirement to the "framebuffer attachement completeness" test.

Originally this extension had several layers of which affected framebuffer completness. They were:

- framebuffer-attachable image completeness
    * image has non-zero width/height/depth
    * image has color, depth, or stencil format
    * image is not from a proxy texture

- framebuffer attachment completeness
    * attached image is textures/renderbuffer
    * attached image is from existing object
    * attached image has format appropriate for attachment point (depth buffer has depth format, etc)

```
            - framebuffer completeness
                * all attachment points are "attachment complete"
                * all images are "framebuffer-attachable image complete"
                * all color buffers have same format
                * draw buffer is attached
                * read buffer is attached
                * framebuffer format combination is supported

        However, upon further reflection of the
        "framebuffer-attachable image completeness" tests, we
        realized that

            a) the requirement that the renderble image is not a
               "proxy" texture was already covered by the fact that
               it's illegal to attach a proxy texture to a
               framebuffer, and

            b) the requirement that the format be color, depth, or
               stencil is essentially already covered by the
               "framebuffer attachment completeness" test
               requirement that the format is appropriate for the
               attachment point.

        This left only the "non-zero-area" test, so we decided to
        fold this requirement into the "framebuffer attachement
        completeness" test and eliminate the concept of
        "framebuffer-attachable image completeness".  This decision
        required the elimination of one of the
        FRAMEBUFFER_INCOMPLETE_* enums as they correspond to the
        conditions in the "framebuffer completeness" test of section
        4.4.4
```

(79) Should the internal format chosen by GL for a texture (or renderbuffer) be invariant with respect to the state of the current framebuffer and its attached images?

```
        RESOLUTION: yes, the choice of internal format must be
        invariant with respect to framebuffer state changes.

        This means that the GL must choose texture internal format
        based only on the arguments to TexImage and ignore the
        current framebuffer state in this selection process.

        Similarly, the GL must choose renderbuffer internal format
        based only on the arguments to RenderbufferStorage and
        ignore the current framebuffer state in this selection
        process.

        This issue is a variant of issue (62).  The OpenGL 2.0
        specification (p.152, paragraph 4) states that:

            "A GL implementation may vary its allocation of
            internal component resolution or compressed internal
            format based on any TexImage3D, TexImage2D (see below),
            or TexImage1D (see below) parameter (except target),
            but the allocation and chosen compressed image format
```

must not be a function of any other state and cannot be
changed once they are established."

Consider that prior to this extension, some implementations may have considered the the bitdepths of the logical buffers of the framebuffer or the bitdepth of the display when choosing an internal format for textures. Since, in practice, these bitdepths typically were immutable for the lifetime of a GL context, the invariance requirements were met.

With the introduction of EXT_framebuffer_object, however, the logical buffer bitdepths can change over the lifetime of the context. So this issue examines whether or not framebuffer state is allowed to affect texture internal format selection.

After some discussion, we felt it was too problematic to introduce this type of invariance. So this extension makes no modifications to the invariance language, and adds similar invariance language applicable to renderbuffer objects. As long as the app provides the same arguments to TexImage{1D|2D|3D} or RenderbufferStorage, then the GL must always choose the same internal format.

Note, however, that the GL is not required to provide the same internal format resolution for renderbuffers as it does for textures.

(80) Should attachment routines be display-list'able?

RESOLUTION: no, in fact none of the routines introduced in this extension are included in display lists.

Initially, we were just considering whether or not the framebuffer attachement routines should be included in display lists. The rationale for not including them was that since query routines can not be in display lists, and well-behaved apps should call the query routine CheckFramebufferStatusEXT() after calling making changes to framebuffer attachments, it was not possible to write a well-behaved app that uses display lists to build up and use a framebuffer. So, one possible solution was to simply disallow from display lists the routines that change change the result of CheckFramebufferStatusEXT().

However, we realized on further consideration that other routines which can affect the results of CheckFramebufferStatusEXT are already allowed in display lists. Namely, the routines which affect textures (TexImage and friends). So, disallowing the attachment routines is a partial solution at best.

We also looked for various precedents and found some mixed results:

- VBO bind operations are not display-list'able, but this is primarily because the VBO bindings are considered client-state

- texture bindings are display-list'able

In the end, though we decided to not include the routines introduced by this extension in display lists for reasons of simplicity more than anything else.

It's possible we may need to add support for display lists back in during promotion of this extension if we determine that it is needed later, but for now, we leave this out.

(81) How should PushAttrib and PopAttrib work with this extension?

RESOLUTION: mostly deferred for now, may revisit later

This extension introduces no new push/pop attrib bits to cover the state introduced by this extension (for instance there is no FRAMEBUFFER_BIT). So the only real question to answer is what effect should Push/Pop attrib have on any existing state as it relates to this extension.

In particular, how should Push/PopAttrib of the COLOR_BUFFER_BIT which covers the DRAW_BUFFER and READ_BUFFER state interact with this extension? Does the COLOR_BUFFER_BIT affect the per-object DRAW_BUFFER and READ_BUFFER state?

Currently, the answer is yes. PushAttrib(COLOR_BUFFER_BIT) saves the DRAW_BUFFER value of the currently bound framebuffer object. If the app later calls PopAttrib() this saved value will be restored even if the framebuffer bound at the time PopAttrib is called is different from the framebuffer bound at the time PushAttrib was called.

In other words, one are considering whether or not it is strange that PushAttrib(COLOR_BUFFER_BIT) affects a piece of per-object state. Note that this is somewhat similar to the way that a PushAttrib(TEXTURE_BIT) can save off per-texture-object state and a later call to PopAttrib can restore that per-object state even if the texture bound at PopAttrib time has since been changed/ deleted/modified in some way.

There are some differences with the texture analogy though. Namely, the TEXTURE_BIT does include the texture bindings so at least the texture object binding is restored in conjunction with the per-texture-object state. Also, some may consider the fact that the TEXTURE_BIT affects per-texture-object state more intuitive than the fact that the COLOR_BUFFER_BIT affects per-framebuffer-object state.

Also, there is a larger discussion going on in the ARB right now about whether PushAttrib/PopAttrib save references to existing bound objects or only the state values which name an existing bound object.

For now, we have deferred further discussion of the PushAttrib/PopAttrib semantics in this extension until the larger issues are cleared up.

(82) What is the relationship between a "binding" and an "attachment"?

RESOLUTION: resolved, the concept of attachment is described below, though final implications will be affected by larger ARB discussions about object sharing and multiple context semantics.

> "Attaching" is the act of connecting one object to another object.
>
> An "attach" operation is similar to a "bind" operation in that both represent a reference to the attached or bound object for the purpose of managing object lifetimes and both enable manipulation of the state of the attached or bound object.
>
> However, an "attach" is also different from a "bind" in that "binding" an unused object creates a new object, while "attaching" does not. Additionally, "bind" establishes a connection between a context and an object, while "attach" establishes a connection between two objects.
>
> Finally, if object "A" is attached to object "B" and object "B" is bound to context "C", then in principle, we treat "A" as if it is <implicitly> bound to "C".
>
> The larger ARB is currently attempting to more clearly define the mutliple context semantics as they relate to object sharing and binding. The final implications for EXT_framebuffer_object may not be clear until those discussions are resolved. This extension may need an update once those issues are addressed.

(83) We use a non-zero framebuffer binding to enable the use of this extension. Should we instead consider using an explicit enable?

RESOLVED: no, retain the "non-zero-binding means enable" semantics.

Currently we enable the use of an application-created framebuffer by binding a non-zero framebuffer object to FRAMEBUFFER_EXT binding point. If the framebuffer binding is zero, then the extension is disabled (i.e., we use the window-system-provided framebuffer).

It might be cleaner to be able to say things like, "when FRAMEBUFFER_OBJECT is enabled", rather than "when the framebuffer binding is not zero", and add an explicit enable. Doing so would also allow changing framebuffer object attachments while FBO is disabled, which might result in the driver doing less validation while the application is setting up framebuffer objects. It would also provide a cleaner way to explain that the permitted DRAW_BUFFER and READ_BUFFER values change when the extension is enabled/disabled.

There are a few object model precedents to choose from: Textures and ARB Vertex and Framgment Program extensions use the explicit enable state. However, Vertex Buffer Objects, Pixel Buffer Objects, and GLSL Vertex and Fragment shaders use a non-zero-binding to enable the use of those features.

If we used an explicit enable, then we could allow creation of an object named zero. Precedent dictates that an object named zero is never shared in the context share group. All other framebuffer objects are shared across the share group. It might be cleaner to disallow creation of an object named zero anyway.

Since binding to zero disables the extension, one way to think about this is that there is an object named zero which is managed through MakeCurrent, MakeContextCurrent, and the window manager. All other objects are managed through FramebufferTexture, FramebufferRenderbuffer, and the operations that define/modify texture and renderbuffer images. When looked at in this light, lack of an explicit enable is not as strange.

(84) Do we need to add any language to describe the y-orientation of framebuffer-attachable images? Specifically, what coordinate system is used by images attached to the framebuffer?

Resolution: unresolved

GL defines the rendering origin at the lower-left corner. Yet, because of the differences between orientation storage of textures and images, pbuffer rendering is often implemented using a "y-inverted" coordinate system. Is this y-inversion exposed in the API?

Is the origin in the lower-left? Upper-left? Do we need to say anything about this at all, or is it already covered by existing GL language?

Currently there is place-holder text in section 4.4.2.3

The intent of this specification is simply to mirror the y-orientation issues of the pbuffer style render to texture API's. What's unclear is whether this requires any new language in this specification or not.

(85) Explain what happens when the FBO has a different width/height from the window?

An FBO takes on the width/height of its attachments. This width/height can be different than the width/height of the window (of framebuffer "zero").

In such cases, after calling BindFramebuffer, it is the application's responsibility to set the glViewport and the glScissor (if necessary) to match that of the new framebuffer binding.

Some background: The default viewport for a context is defined by the dimensions of the window to which the context is first made current. When the window is resized, or when the context is bound to a different window, the viewport does not change automatically. It has always been the application's responsibility to set the viewport after one of these events. FBO is no different; after BindFramebuffer it is the application's responsibility to set the viewport if the new framebuffer binding has a different width/height than the old binding..

(86) Are any one- or two- component formats color-renderable?

Presently none of the one- or two- component texture formats defined in unextended OpenGL is color-renderable. The R and RG float formats defined by the NV_float_buffer extension are color-renderable.

Although an early draft of the FBO specification permitted rendering into alpha, luminance, and intensity formats, this this capability was pulled when it was realized that it was under-specified exactly how rendering into these formats would work. (specifically, how R/G/B/A map to I/L/A)

To resolve this we seem to have two options:

A) Add new R and RG formats like NV_float_buffer did.

B) For the existing one- and two- component formats, define the mapping from RGBA components to ILA components.

The superbuffers group has informally decided that option A is preferable.

(87) What happens if a single image is attached more than once to a framebuffer object?

RESOLVED: The value written to the pixel is undefined.

There used to be a rule in section 4.4.4.2 that resulted in FRAMEBUFFER_INCOMPLETE_DUPLICATE_ATTACHMENT_EXT if a single image was attached more than once to a framebuffer object.

```
    FRAMEBUFFER_INCOMPLETE_DUPLICATE_ATTACHMENT_EXT   0x8CD8
```

```
            * A single image is not attached more than once to the
              framebuffer object.

              { FRAMEBUFFER_INCOMPLETE_DUPLICATE_ATTACHMENT_EXT }

        This rule was removed in version #117 of the
        EXT_framebuffer_object specification after discussion at the
        September 2005 ARB meeting.  The rule essentially required an
        O(n*lg(n)) search.  Some implementations would not need to do that
        search if the completeness rules did not require it.  Instead,
        language was added to section 4.10 which says the values
        written to the framebuffer are undefined when this rule is
        violated.
```

Dependencies

    OpenGL 1.1 required

    This extension is written against the OpenGL 2.0 (September 7,
    2004) specification.

    WGL_EXT_extensions_string is required for WGL support.

    WGL_EXT_pixel_format is required for WGL support.

    ARB_color_buffer_float interacts with this extension.

    EXT_framebuffer_object interacts with this extension.

EXT_texture_sRGB interacts with this extension.

ARB_draw_buffers interacts with this extension.

Overview

Conventionally, OpenGL assumes framebuffer color components are stored in a linear color space. In particular, framebuffer blending is a linear operation.

The sRGB color space is based on typical (non-linear) monitor characteristics expected in a dimly lit office. It has been standardized by the International Electrotechnical Commission (IEC) as IEC 61966-2-1. The sRGB color space roughly corresponds to 2.2 gamma correction.

This extension adds a framebuffer capability for sRGB framebuffer update and blending. When blending is disabled but the new sRGB updated mode is enabled (assume the framebuffer supports the capability), high-precision linear color component values for red, green, and blue generated by fragment coloring are encoded for sRGB prior to being written into the framebuffer. When blending is enabled along with the new sRGB update mode, red, green, and blue framebuffer color components are treated as sRGB values that are converted to linear color values, blended with the high-precision color values generated by fragment coloring, and then the blend result is encoded for sRGB just prior to being written into the framebuffer.

The primary motivation for this extension is that it allows OpenGL applications to render into a framebuffer that is scanned to a monitor configured to assume framebuffer color values are sRGB encoded. This assumption is roughly true of most PC monitors with default gamma correction. This allows applications to achieve faithful color reproduction for OpenGL rendering without adjusting the monitor's gamma correction.

New Procedures and Functions

None

New Tokens

Accepted by the <attribList> parameter of glXChooseVisual, and by the <attrib> parameter of glXGetConfig:

```
    GLX_FRAMEBUFFER_SRGB_CAPABLE_EXT             0x20B2
```

Accepted by the <piAttributes> parameter of wglGetPixelFormatAttribivEXT, wglGetPixelFormatAttribfvEXT, and the <piAttribIList> and <pfAttribIList> of wglChoosePixelFormatEXT:

```
    WGL_FRAMEBUFFER_SRGB_CAPABLE_EXT             0x20A9
    Accepted by the <cap> parameter of Enable, Disable, and IsEnabled,
    and by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv,
    and GetDoublev:

        FRAMEBUFFER_SRGB_EXT                        0x8DB9

    Accepted by the <pname> parameter of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

        FRAMEBUFFER_SRGB_CAPABLE_EXT                0x8DBA
```

None

Additions to Chapter 3 of the 2.0 Specification (Rasterization)

None

Additions to Chapter 4 of the 2.0 Specification (Per-Fragment Operations and the Frame Buffer)

DELETE the following sentence from section 4.1.8 (Blending) because it is moved to the new "sRGB Conversion" section:

"Each of these floating-point values is clamped to [0,1] and converted back to a fixed-point value in the manner described in section 2.14.9."

If ARB_color_buffer_float is supported, the following paragraph is modified to eliminate the fixed-point clamping and conversion because this behavior is moved to the new "sRGB Conversion" section.

"If the color buffer is fixed-point, the components of the source and destination values and blend factors are clamped to [0, 1] prior to evaluating the blend equation, the components of the blending result are clamped to [0,1] and converted to fixed-point values in the manner described in section 2.14.9. If the color buffer is floating-point, no clamping occurs. The resulting four values are sent to the next operation."

The modified ARB_color_buffer_float paragraph should read:

"If the color buffer is fixed-point, the components of the source and destination values and blend factors are clamped to [0, 1] prior to evaluating the blend equation. If the color buffer is floating-point, no clamping occurs. The resulting four values are sent to the next operation."

```
    Replace the following sentence:

    "Destination (framebuffer) components are taken to be fixed-point
    values represented according to the scheme in section 2.14.9 (Final
    Color Processing), as are source (fragment) components."

    with the following sentences:

    "Destination (framebuffer) components are taken to be fixed-point
    values represented according to the scheme in section 2.14.9 (Final
    Color Processing).  If FRAMEBUFFER_SRGB_EXT is enabled and the boolean
    FRAMEBUFFER_SRGB_CAPABLE_EXT state for the drawable is true, the R,
    G, and B destination color values (after conversion from fixed-point
    to floating-point) are considered to be encoded for the sRGB color
    space and hence need to be linearized prior to their use in blending.
    Each R, G, and B component is linearized by some approximation of
    the following:

            {  cs / 12.92,                 cs <= 0.04045
       cl = {
            {  ((cs + 0.055)/1.055)^2.4,   cs >  0.04045

    where cs is the component value prior to linearization and cl is
    the result.  Otherwise if FRAMEBUFFER_SRGB_EXT is disabled, or the
    drawable is not sRGB capable, or the value corresponds to the A
    component, then cs = cl for such components.  The corresponding cs
    values for R, G, B, and A are recombined as the destination color
    used subsequently by blending."

    ADD new section 4.1.X "sRGB Conversion" after section 4.1.8 (Blending)
    and before section 4.1.9 (Dithering).  With this new section added,
    understand the "next operation" referred to in the section 4.1.8
    (Blending) to now be "sRGB Conversion" (instead of "Dithering").

    "If FRAMEBUFFER_SRGB_EXT is enabled and the boolean
    FRAMEBUFFER_SRGB_CAPABLE_EXT state for the drawable is true, the R,
    G, and B values after blending are converted into the non-linear
    sRGB color space by some approximation of the following:

             {  0.0,                          0         <= cl
             {  12.92 * c,                    0         <  cl < 0.0031308
        cs = {  1.055 * cl^0.41666 - 0.055,   0.0031308 <= cl < 1
             {  1.0,                                       cl >= 1

    where cl is the R, G, or B element and cs is the result
    (effectively converted into an sRGB color space).  Otherwise if
    FRAMEBUFFER_SRGB_EXT is disabled, or the drawable is not sRGB
    capable, or the value corresponds to the A element, then cs = cl
    for such elements.

    The resulting cs values form a new RGBA color value.  If the color
    buffer is fixed-point, the components of this RGBA color value are
    clamped to [0,1] and then converted to a fixed-point value in the
    manner described in section 2.14.9.  The resulting four values are
    sent to the subsequent dithering operation."
```

Dependencies on ARB_color_buffer_float

If ARB_color_buffer_float is not supported, ignore the edits to ARB_color_buffer_float language.

Dependencies on EXT_texture_sRGB and EXT_framebuffer_object

If EXT_texture_sRGB and EXT_framebuffer_object are both supported, the implementation should set FRAMEBUFFER_SRGB_CAPABLE_EXT to false when rendering to a color texture that is not one of the EXT_texture_sRGB introduced internal formats. An implementation can determine whether or not it will set FRAMEBUFFER_SRGB_CAPABLE_EXT to true for the EXT_texture_sRGB introduced internal formats. Implementations are encouraged to allow sRGB update and blending when rendering to sRGB textures using EXT_framebuffer_object but this is not required. In any case, FRAMEBUFFER_SRGB_CAPABLE_EXT should indicate whether or not sRGB update and blending is supported.

Dependencies on ARB_draw_buffers, EXT_texture_sRGB, and EXT_framebuffer_object

If ARB_draw_buffers, EXT_texture_sRGB, and EXT_framebuffer_object are supported and an application attempts to render to a set of color buffers where some but not all of the color buffers are FRAMEBUFFER_SRGB_CAPABLE_EXT individually, the query of FRAMEBUFFER_SRGB_CAPABLE_EXT should return true.

However sRGB update and blending only apply to the color buffers that are actually sRGB-capable.

GLX Protocol

None.

Errors

Relaxation of INVALID_ENUM errors

Enable, Disable, IsEnabled, GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev now accept the new token as allowed in the "New Tokens" section.

New State

    Add to table 6.20 (Pixel Operations)

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
FRAMEBUFFER_SRGB_EXT	B	IsEnabled	False	sRGB update and blending enable	4.1.X	color-buffer/enable

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
FRAMEBUFFER_SRGB_CAPABLE_EXT	B	IsEnabled	-	true if drawable supports sRGB update and blending	4.1.X	-

New Implementation Dependent State

    None

Issues

    1) *What should this extension be called?*

        RESOLVED: EXT_framebuffer_sRGB.

        The "EXT_framebuffer" part indicates the extension is in
        the framebuffer domain and "sRGB" indicates the extension is
        adding a set of sRGB formats. This mimics the naming of the
        EXT_texture_sRGB extension that adds sRGB texture formats.

        The mixed-case spelling of sRGB is the established usage so
        "_sRGB" is preferred to "_srgb". The "s" stands for standard
        (color space).

        For token names, we use "SRGB" since token names are uniformly
        capitalized.

    2) *Should alpha be sRGB encoded?*

        RESOLVED: No. Alpha remains linear.

        A rationale for this resolution is found in Alvy Ray's "Should
        Alpha Be Nonlinear If RGB Is?" Tech Memo 17 (December 14, 1998).
        See: ftp://ftp.alvyray.com/Acrobat/17_Nonln.pdf

    3) *Should the ability to support sRGB framebuffer update and blending
        be an attribute of the framebuffer?*

        RESOLVED: Yes. It should be a capability of some pixel formats
        (mostly likely just RGB8 and RGBA8) that says sRGB blending can
        be enabled.

        This allows an implementation to simply mark the existing RGB8
        and RGBA8 pixel formats as supporting sRGB blending and then

    just provide the functionality for sRGB update and blending for
    such formats.

    sRGB support for floating-point formats makes little sense
    (because floating-point already provide a non-linear distribution
    of precision and typically have considerably more precision
    than 8-bit fixed-point framebuffer components allow) and would
    be expensive to support.

    Requiring sRGB support for all fixed-point buffers means that
    support for 16-bit components or very small 5-bit or 6-bit
    components would require special sRGB conversion hardware.
    Typically sRGB is well-suited for 8-bit fixed-point components
    so we do not want this extension to require expensive tables
    for other component sizes that are unlikely to ever be used.
    Implementations could support sRGB conversion for any color
    framebuffer format but implementations are not required to
    (honestly nor are implementations like to support sRGB on anything
    but 8-bit fixed-point color formats).

4) *Should there be an enable for sRGB update and blending?*

    RESOLVED: Yes, and it is disabled by default. The enable only
    applies if the framebuffer's underlying pixel format is capable
    of sRGB update and blending. Otherwise, the enable is silently
    ignored (similar to how the multisample enables are ignored when
    the pixel format lacks multisample supports).

5) How is sRGB blending done?

    RESOLVED: Blending is a linear operation so should be performed
    on values in linear spaces. sRGB-encoded values are in a
    non-linear space so sRGB blending should convert sRGB-encoded
    values from the framebuffer to linear values, blend, and then
    sRGB-encode the result to store it in the framebuffer.

    The destination color RGB components are each converted
    from sRGB to a linear value. Blending is then performed.
    The source color and constant color are simply assumed to be
    treated as linear color components. Then the result of blending
    is converted to an sRGB encoding and stored in the framebuffer.

6) *What happens if GL_FRAMEBUFFER_SRGB_EXT is enabled (and
    GL_FRAMEBUFFER_SRGB_CAPABLE_EXT is true for the drawable) but
    GL_BLEND is not enabled?*

    RESOLVED: The color result from fragment coloring (the source
    color) is converted to an sRGB encoding and stored in the
    framebuffer.

7) *How are multiple render targets handled?*

    RESOLVED: Render targets that are not
    GL_FRAMEBUFFER_SRGB_CAPABLE_EXT ignore the state of the
    GL_FRAMEBUFFER_SRGB_EXT enable for sRGB update and blending.
    So only the render targets that are sRGB-capable perform sRGB
    blending and update when GL_FRAMEBUFFER_SRGB_EXT is enabled.

```
    8)  Should sRGB framebuffer support affect the pixel path?

        RESOLVED:  No.

        sRGB conversion only applies to color reads for blending and
        color writes.  Color reads for glReadPixels, glCopyPixels,
        or glAccum have no sRGB conversion applied.

        For pixel path operations, an application could use pixel maps
        or color tables to perform an sRGB-to-linear conversion with
        these lookup tables.

    9)  Can luminance (single color component) framebuffer formats
        support sRGB blending?

        RESOLVED:  Yes, if an implementation chooses to advertise such
        a format and set the sRGB attribute for the format too.

        Implementations are not obliged to provide such formats.

    10) Should all component sizes be supported for sRGB components or
        just 8-bit?

        RESOLVED:  This is at the implementation's discretion since
        the implementation decides what pixel formats such support sRGB
        update and blending.

        It likely implementations will only provide sRGB-capable
        framebuffer configurations for configurations with 8-bit
        components.

    11) What must be specified as far as how do you convert to and from
        sRGB and linear RGB color spaces?

        RESOLVED:  The specification language needs to only supply the
        linear RGB to sRGB conversion (see section 4.9.X above).

        The sRGB to linear RGB conversion is documented in the
        EXT_texture_sRGB specification.

        For completeness, the accepted linear RGB to sRGB conversion
        (the inverse of the function specified in section 3.8.x) is as
        follows:
```

Given a linear RGB component, cl, convert it to an sRGB component, cs, in the range [0,1], with this pseudo-code:

```
if (isnan(cl)) {
    /* Map IEEE-754 Not-a-number to zero. */
    cs = 0.0;
} else if (cl > 1.0) {
    cs = 1.0;
} else if (cl < 0.0) {
    cs = 0.0;
} else if (cl < 0.0031308) {
    cs = 12.92 * cl;
} else {
    cs = 1.055 * pow(cl, 0.41666) - 0.055;
}
```

The NaN behavior in the pseudo-code is recommended but not specified in the actual specification language.

sRGB components are typically stored as unsigned 8-bit fixed-point values. If cs is computed with the above pseudo-code, cs can be converted to a [0,255] integer with this formula:

```
csi = floor(255.0 * cs + 0.5)
```

12) *Does this extension guarantee images rendered with sRGB textures will "look good" when output to a device supporting an sRGB color space?*

RESOLVED: No.

Whether the displayed framebuffer is displayed to a monitor that faithfully reproduces the sRGB color space is beyond the scope of this extension. This involves the gamma correction and color calibration of the physical display device.

13) *How does this extension interact with EXT_framebuffer_object?*

RESOLVED: When rendering to a color texture, an application can query GL_FRAMEBUFFER_SRGB_CAPABLE_EXT to determine if the color texture image is capable of sRGB rendering.

This boolean should be false for all texture internal formats except may be true (but are not required to be true) for the sRGB internal formats introduced by EXT_texture_sRGB. The expectation is that implementations of this extension will be able to support sRGB update and blending of sRGB textures.

14) *How is the constant blend color handled for sRGB framebuffers?*

RESOLVED: The constant blend color is specified as four floating-point values. Given that the texture border color can be specified at such high precision, it is always treated as a linear RGBA value.

15) *How does glCopyTex[Sub]Image work with sRGB? Suppose we're rendering to a floating point pbuffer or framebuffer object and do CopyTexImage. Are the linear framebuffer values converted to sRGB during the copy?*

RESOLVED: No, linear framebuffer values will NOT be automatically converted to the sRGB encoding during the copy. If such a conversion is desired, as explained in issue 12, the red, green, and blue pixel map functionality can be used to implement a linear-to-sRGB encoding translation.

16) *Should this extension explicitly specify the particular sRGB-to-linear and linear-to-sRGB conversions it uses?*

RESOLVED: The conversions are explicitly specified but allowance for approximations is provided. The expectation is that the implementation is likely to use a table to implement the conversions the conversion is necessarily then an approximation.

17) How does this extension interact with multisampling?

RESOLVED: There are no explicit interactions. However, arguably if the color samples for multisampling are sRGB encoded, the samples should be linearized before being "resolved" for display and then recoverted to sRGB if the output device expects sRGB encoded color components.

This is really a video scan-out issue and beyond the scope of this extension which is focused on the rendering issues. However some implementation advice is provided:

The implementation sufficiently aware of the gamma correction configured for the display device could decide to perform an sRGB-correct multisample resolve. Whether this occurs or not could be determined by a control panel setting or inferred by the application's use of this extension.

18) Why is the sRGB framebuffer GL_FRAMEBUFFER_SRGB_EXT enable disabled by default?

RESOLVED: This extension could have a boolean sRGB-versus-non-sRGB pixel format configuration mode that determined whether or not sRGB framebuffer update and blending occurs. The problem with this approach is 1) it creates may more pixel formation configurations because sRGB and non-sRGB versions of lots of existing configurations must be advertised, and 2) applicaitons unaware of sRGB might unknowingly select an sRGB configuration and then generate over-bright rendering.

It seems more appropriate to have a capability for sRGB framebuffer update and blending that is disabled by default. This allows existing RGB8 and RGBA8 framebuffer configurations to be marked as sRGB capable (so no additional configurations need be enumerated). Applications that desire sRGB rendering should identify an sRGB-capable framebuffer configuration and then enable sRGB rendering.

This is different from how EXT_texture_sRGB handles sRGB support for texture formats. In the EXT_texture_sRGB extension, textures are either sRGB or non-sRGB and there is no texture parameter to switch textures between the two modes. This makes sense for EXT_texture_sRGB because it allows implementations to fake sRGB textures with higher-precision linear textures that simply convert sRGB-encoded texels to sufficiently precise linear RGB values.

Texture formats also don't have the problem enumerated pixel format descriptions have where a naive application could stumble upon an sRGB-capable pixel format. sRGB textures require explicit use of one of the new EXT_texture_sRGB-introduced internal formats.

19) How does sRGB and this extension interact with digital video output standards, in particular DVI?

RESOLVED: The DVI 1.0 specification recommends "as a default position that digital moniotrs of all types support a color transfer function similar to analog CRT monitors (gamma=2.2) which makes up the majority of the compute display market." This means DVI output devices should benefit from blending in the sRGB color space just like analog monitors.

    GL_EXT_fog_coord

Status

    Shipping (version 1.6)

Version

    $Date: 1999/06/21 19:57:19 $ $Revision: 1.11 $

Number

    149

Dependencies

    OpenGL 1.1 is required.
    The extension is written against the OpenGL 1.2 Specification.

Overview

    This extension allows specifying an explicit per-vertex fog
    coordinate to be used in fog computations, rather than using a
    fragment depth-based fog equation.

Issues

```
  * Should the specified value be used directly as the fog weighting
    factor, or in place of the z input to the fog equations?

        As the z input; more flexible and meets ISV requests.

  * Do we want vertex array entry points? Interleaved array formats?

        Yes for entry points, no for interleaved formats, following the
        argument for secondary_color.

  * Which scalar types should FogCoord accept? The full range, or just
    the unsigned and float versions? At the moment it follows Index(),
    which takes unsigned byte, signed short, signed int, float, and
    double.

        Since we're now specifying a number which behaves like an
        eye-space distance, rather than a [0,1] quantity, integer types
        are less useful. However, restricting the commands to floating
        point forms only introduces some nonorthogonality.

        Restrict to only float and double, for now.
  * Interpolation of the fog coordinate may be perspective-correct or
    not. Should this be affected by PERSPECTIVE_CORRECTION_HINT,
    FOG_HINT, or another to-be-defined hint?

        PERSPECTIVE_CORRECTION_HINT; this is already defined to affect
        all interpolated parameters. Admittedly this is a loss of
        orthogonality.

  * Should the current fog coordinate be queryable?

        Yes, but it's not returned by feedback.

  * Control the fog coordinate source via an Enable instead of a fog
    parameter?

        No. We might want to add more sources later.

  * Should the fog coordinate be restricted to non-negative values?

        Perhaps. Eye-coordinate distance of fragments will be
        non-negative due to clipping. Specifying explicit negative
        coordinates may result in very large computed f values, although
        they are defined to be clipped after computation.

  * Use existing DEPTH enum instead of FRAGMENT_DEPTH? Change name of
    FRAGMENT_DEPTH_EXT to FOG_FRAGMENT_DEPTH_EXT?

        Use FRAGMENT_DEPTH_EXT; FOG_FRAGMENT_DEPTH_EXT is somewhat
        misleading, since fragment depth itself has no dependence on
        fog.
```

New Procedures and Functions

```
    void FogCoord[fd]EXT(T coord)
    void FogCoord[fd]vEXT(T coord)
    void FogCoordPointerEXT(enum type, sizei stride, void *pointer)
```

New Tokens

```
    Accepted by the <pname> parameter of Fogi and Fogf:

        FOG_COORDINATE_SOURCE_EXT           0x8450

    Accepted by the <param> parameter of Fogi and Fogf:

        FOG_COORDINATE_EXT                  0x8451
        FRAGMENT_DEPTH_EXT                  0x8452

    Accepted by the <pname> parameter of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

        CURRENT_FOG_COORDINATE_EXT          0x8453
        FOG_COORDINATE_ARRAY_TYPE_EXT       0x8454
        FOG_COORDINATE_ARRAY_STRIDE_EXT     0x8455
    Accepted by the <pname> parameter of GetPointerv:

        FOG_COORDINATE_ARRAY_POINTER_EXT    0x8456

    Accepted by the <array> parameter of EnableClientState and
    DisableClientState:

        FOG_COORDINATE_ARRAY_EXT            0x8457
```

Additions to Chapter 2 of the OpenGL 1.2 Specification (OpenGL Operation)

```
  These changes describe a new current state type, the fog coordinate,
  and the commands to specify it:

  - (2.6, p. 12) Second paragraph changed to:

        "Each vertex is specified with two, three, or four coordinates.
        In addition, a current normal, current texture coordinates,
        current color, and current fog coordinate may be used in
        processing each vertex."

  - 2.6.3, p. 19) First paragraph changed to

        "The only GL commands that are allowed within any Begin/End
        pairs are the commands for specifying vertex coordinates, vertex
        colors, normal coordinates, texture coordinates, and fog
        coordinates (Vertex, Color, Index, Normal, TexCoord,
        FogCoord)..."

  - (2.7, p. 20) Insert the following paragraph following the third
        paragraph describing current normals:

        "   The current fog coodinate is set using
                void FogCoord[fd]EXT(T coord)
                void FogCoord[fd]vEXT(T coord)."

    The last paragraph is changed to read:

        "The state required to support vertex specification consists of
        four floating-point numbers to store the current texture
        coordinates s, t, r, and q, one floating-point value to store
        the current fog coordinate, four floating-point values to store
        the current RGBA color, and one floating-point value to store
        the current color index. There is no notion of a current vertex,
        so no state is devoted to vertex coordinates. The initial values
        of s, t, and r of the current texture coordinates are zero; the
        initial value of q is one. The initial fog coordinate is zero.
        The initial current normal has coordinates (0,0,1). The initial
        RGBA color is (R,G,B,A) = (1,1,1,1). The initial color index is
        1."

  - (2.8, p. 21) Added fog coordinate command for vertex arrays:

    Change first paragraph to read:

        "The vertex specification commands described in section 2.7
        accept data in almost any format, but their use requires many
        command executions to specify even simple geometry. Vertex data
        may also be placed into arrays that are stored in the client's
        address space. Blocks of data in these arrays may then be used
        to specify multiple geometric primitives through the execution
        of a single GL command. The client may specify up to seven
        arrays: one each to store edge flags, texture coordinates, fog
        coordinates, colors, color indices, normals, and vertices. The
        commands"

    Add to functions listed following first paragraph:

        void FogCoordPointerEXT(enum type, sizei stride, void *pointer)

    Add to table 2.4 (p. 22):

        Command                     Sizes   Types
        -------                     -----   -----
        FogCoordPointerEXT          1       float,double

    Starting with the second paragraph on p. 23, change to add
    FOG_COORDINATE_ARRAY_EXT:

        "An individual array is enabled or disabled by calling one of

            void EnableClientState(enum array)
            void DisableClientState(enum array)

        with array set to EDGE_FLAG_ARRAY, TEXTURE_COORD_ARRAY,
        FOG_COORDINATE_ARRAY_EXT, COLOR_ARRAY, INDEX_ARRAY,
        NORMAL_ARRAY, or VERTEX_ARRAY, for the edge flag, texture
        coordinate, fog coordinate, color, color index, normal, or
        vertex array, respectively.

        The ith element of every enabled array is transferred to the GL
        by calling

            void ArrayElement(int i)

        For each enabled array, it is as though the corresponding
        command from section 2.7 or section 2.6.2 were called with a
        pointer to element i. For the vertex array, the corresponding
        command is Vertex<size><type>v, where <size> is one of [2,3,4],
        and <type> is one of [s,i,f,d], corresponding to array types
        short, int, float, and double respectively. The corresponding
        commands for the edge flag, texture coordinate, fog coordinate,
        color, color, color index, and normal arrays are EdgeFlagv,
        TexCoord<size><type>v, FogCoord<type>v, Color<size><type>v,
        Index<type>v, and Normal<type>v, respectively..."
```

```
   Change pseudocode on p. 27 to disable fog coordinate array for
   canned interleaved array formats. After the lines

           DisableClientState(EDGE_FLAG_ARRAY);
           DisableClientState(INDEX_ARRAY);

       insert the line

           DisableClientState(FOG_COORDINATE_ARRAY_EXT);

   Substitute "seven" for every occurence of "six" in the final
   paragraph on p. 27.

 - (2.12, p. 41) Add fog coordinate to the current rasterpos state.

   Change the first sentence of the first paragraph to read

       "The state required for the current raster position consists of
       three window coordinates x_w, y_w, and z_w, a clip coordinate
       w_c value, an eye coordinate distance, a fog coordinate, a valid
       bit, and associated data consisting of a color and texture
       coordinates."

   Change the last paragraph to read

       "The current raster position requires six single-precision
       floating-point values for its x_w, y_w, and z_w window
       coordinates, its w_c clip coordinate, its eye coordinate
       distance, and its fog coordinate, a single valid bit, a color
       (RGBA color and color index), and texture coordinates for
       associated data. In the initial state, the coordinates and
       texture coordinates are both (0,0,0,1), the fog coordinate is 0,
       the eye coordinate distance is 0, the valid bit is set, the
       associated RGBA color is (1,1,1,1), and the associated color
       index color is 1. In RGBA mode, the associated color index
       always has its initial value; in color index mode, the RGBA
       color always maintains its initial value."

 - (3.10, p. 139) Change the second and third paragraphs to read

       "This factor f may be computed according to one of three
       equations:"

           f = exp(-d*c)       (3.24)
           f = exp(-(d*c)^2)   (3.25)
           f = (e-c)/(e-s)     (3.26)

       If the fog source (as defined below) is FRAGMENT_DEPTH_EXT, then
       c is the eye-coordinate distance from the eye, (0 0 0 1) in eye
       coordinates, to the fragment center. If the fog source is
       FOG_COORDINATE_EXT, then c is the interpolated value of the fog
       coordinate for this fragment. The equation and the fog source,
       along with either d or e and s, is specified with

           void Fog{if}(enum pname, T param);
           void Fog{if}v(enum pname, T params);
```

```
        If <pname> is FOG_MODE, then <param> must be, or <param> must
        point to an integer that is one of the symbolic constants EXP,
        EXP2, or LINEAR, in which case equation 3.24, 3.25, or 3.26,,
        respectively, is selected for the fog calculation (if, when 3.26
        is selected, e = s, results are undefined). If <pname> is
        FOG_COORDINATE_SOURCE_EXT, then <param> is or <params> points to
        an integer that is one of the symbolic constants
        FRAGMENT_DEPTH_EXT or FOG_COORDINATE_EXT. If <pname> is
        FOG_DENSITY, FOG_START, or FOG_END, then <param> is or <params>
        points to a value that is d, s, or e, respectively. If d is
        specified less than zero, the error INVALID_VALUE results."

  - (3.10, p. 140) Change the last paragraph preceding section 3.11
    to read

        "The state required for fog consists of a three valued integer
        to select the fog equation, three floating-point values d, e,
        and s, an RGBA fog color and a fog color index, a two-valued
        integer to select the fog coordinate source, and a single bit to
        indicate whether or not fog is enabled. In the initial state,
        fog is disabled, FOG_COORDINATE_SOURCE_EXT is
        FRAGMENT_DEPTH_EXT, FOG_MODE is EXP, d = 1.0, e = 1.0, and s =
        0.0; C_f = (0,0,0,0) and i_f=0."

GLX Protocol

    Two new GL rendering commands are added. The following commands are
    sent to the server as part of a glXRender request:

```
        FogCoordfvEXT
            2           8               rendering command length
            2           4124            rendering command opcode
            4           FLOAT32         v[0]

        FogCoorddvEXT
            2           12              rendering command length

Revision History

* Revision 1.6 - Functionality complete

* Revision 1.7-1.9 - Fix typos and add fields to bring up to date with
  the new extension template. No functionality changes.

Name

    EXT_geometry_shader4

Name String

    GL_EXT_geometry_shader4

Contact

    Pat Brown, NVIDIA (pbrown 'at' nvidia.com)
    Barthold Lichtenbelt, NVIDIA (blichtenbelt 'at' nvidia.com)

Status

    Multi-vendor extension

    Shipping for GeForce 8 Series (November 2006)

Version

    Last Modified Date: 05/22/2007
    NVIDIA Revision: 17

Number

    324

Dependencies

    OpenGL 1.1 is required.

    This extension is written against the OpenGL 2.0 specification.

    EXT_framebuffer_object interacts with this extension.

    EXT_framebuffer_blit interacts with this extension.

    EXT_texture_array interacts with this extension.

    ARB_texture_rectangle trivially affects the definition of this
    extension.

    EXT_texture_buffer_object trivially affects the definition of this
    extension.

    NV_primitive_restart trivially affects the definition of this
    extension.

    This extension interacts with EXT_tranform_feedback.

Overview

    EXT_geometry_shader4 defines a new shader type available to be run on the
    GPU, called a geometry shader. Geometry shaders are run after vertices are
    transformed, but prior to color clamping, flat shading and clipping.

A geometry shader begins with a single primitive (point, line, triangle). It can read the attributes of any of the vertices in the primitive and use them to generate new primitives. A geometry shader has a fixed output primitive type (point, line strip, or triangle strip) and emits vertices to define a new primitive. A geometry shader can emit multiple disconnected primitives. The primitives emitted by the geometry shader are clipped and then processed like an equivalent OpenGL primitive specified by the application.

Furthermore, EXT_geometry_shader4 provides four additional primitive types: lines with adjacency, line strips with adjacency, separate triangles with adjacency, and triangle strips with adjacency. Some of the vertices specified in these new primitive types are not part of the ordinary primitives, instead they represent neighboring vertices that are adjacent to the two line segment end points (lines/strips) or the three triangle edges (triangles/tstrips). These vertices can be accessed by geometry shaders and used to match up the vertices emitted by the geometry shader with those of neighboring primitives.

Since geometry shaders expect a specific input primitive type, an error will occur if the application presents primitives of a different type. For example, if a geometry shader expects points, an error will occur at Begin() time, if a primitive mode of TRIANGLES is specified.

New Procedures and Functions

```
void ProgramParameteriEXT(uint program, enum pname, int value);
void FramebufferTextureEXT(enum target, enum attachment,
                           uint texture, int level);
void FramebufferTextureLayerEXT(enum target, enum attachment,
                                uint texture, int level, int layer);
void FramebufferTextureFaceEXT(enum target, enum attachment,
                               uint texture, int level, enum face);
```

New Tokens

Accepted by the <type> parameter of CreateShader and returned by the <params> parameter of GetShaderiv:

```
    GEOMETRY_SHADER_EXT                             0x8DD9
```

Accepted by the <pname> parameter of ProgramParameteriEXT and GetProgramiv:

```
    GEOMETRY_VERTICES_OUT_EXT                       0x8DDA
    GEOMETRY_INPUT_TYPE_EXT                         0x8DDB
    GEOMETRY_OUTPUT_TYPE_EXT                        0x8DDC
Accepted by the <pname> parameter of GetBooleanv, GetIntegerv,
GetFloatv, and GetDoublev:

    MAX_GEOMETRY_TEXTURE_IMAGE_UNITS_EXT             0x8C29
    MAX_GEOMETRY_VARYING_COMPONENTS_EXT              0x8DDD
    MAX_VERTEX_VARYING_COMPONENTS_EXT                0x8DDE
    MAX_VARYING_COMPONENTS_EXT                       0x8B4B
    MAX_GEOMETRY_UNIFORM_COMPONENTS_EXT              0x8DDF
    MAX_GEOMETRY_OUTPUT_VERTICES_EXT                 0x8DE0
    MAX_GEOMETRY_TOTAL_OUTPUT_COMPONENTS_EXT         0x8DE1

Accepted by the <mode> parameter of Begin, DrawArrays,
MultiDrawArrays, DrawElements, MultiDrawElements, and
DrawRangeElements:

    LINES_ADJACENCY_EXT                              0xA
    LINE_STRIP_ADJACENCY_EXT                         0xB
    TRIANGLES_ADJACENCY_EXT                          0xC
    TRIANGLE_STRIP_ADJACENCY_EXT                     0xD

Returned by CheckFramebufferStatusEXT:

    FRAMEBUFFER_INCOMPLETE_LAYER_TARGETS_EXT         0x8DA8
    FRAMEBUFFER_INCOMPLETE_LAYER_COUNT_EXT           0x8DA9

Accepted by the <pname> parameter of GetFramebufferAttachment-
ParameterivEXT:

    FRAMEBUFFER_ATTACHMENT_LAYERED_EXT               0x8DA7
    FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER_EXT         0x8CD4

Accepted by the <cap> parameter of Enable, Disable, and IsEnabled,
and by the <pname> parameter of GetIntegerv, GetFloatv, GetDoublev,
and GetBooleanv:

    PROGRAM_POINT_SIZE_EXT                           0x8642

(Note: FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER_EXT is simply an alias for the
FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET_EXT token provided in
EXT_framebuffer_object.  This extension generalizes the notion of
"<zoffset>" to include layers of an array texture.)

(Note:  PROGRAM_POINT_SIZE_EXT is simply an alias for the
VERTEX_PROGRAM_POINT_SIZE token provided in OpenGL 2.0, which is itself an
alias for VERTEX_PROGRAM_POINT_SIZE_ARB provided by
ARB_vertex_program. Program-computed point sizes can be enabled if
geometry shaders are enabled.)
```

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

Modify Section 2.6.1 (Begin and End Objects), p. 13

(Add to end of section, p. 18)

(add figure)

```
    1 - - - 2----->3 - - - 4     1 - - - 2--->3--->4--->5 - - - 6

    5 - - - 6----->7 - - - 8

           (a)                              (b)
```

Figure 2.X1 (a) Lines with adjacency, (b) Line strip with adjacency. The vertices connected with solid lines belong to the main primitives; the vertices connected by dashed lines are the adjacent vertices that may be used in a geometry shader.

Lines with Adjacency

Lines with adjacency are independent line segments where each endpoint has a corresponding "adjacent" vertex that can be accessed by a geometry shader (Section 2.16). If a geometry shader is not active, the "adjacent" vertices are ignored.

A line segment is drawn from the 4i + 2nd vertex to the 4i + 3rd vertex for each i = 0, 1, ... , n-1, where there are 4n+k vertices between the Begin and End. k is either 0, 1, 2, or 3; if k is not zero, the final k vertices are ignored. For line segment i, the 4i + 1st and 4i + 4th vertices are considered adjacent to the 4i + 2nd and 4i + 3rd vertices, respectively. See Figure 2.X1.

Lines with adjacency are generated by calling Begin with the argument value LINES_ADJACENCY_EXT.

Line Strips with Adjacency

Line strips with adjacency are similar to line strips, except that each line segment has a pair of adjacent vertices that can be accessed by a geometry shader (Section 2.15). If a geometry shader is not active, the "adjacent" vertices are ignored.

A line segment is drawn from the i + 2nd vertex to the i + 3rd vertex for each i = 0, 1, ..., n-1, where there are n+3 vertices between the Begin and End. If there are fewer than four vertices between a Begin and End, all vertices are ignored. For line segment i, the i + 1st and i + 4th vertex are considered adjacent to the i + 2nd and i + 3rd vertices, respectively. See Figure 2.X1.

Line strips with adjacency are generated by calling Begin with the argument value LINE_STRIP_ADJACENCY_EXT.

                           \   |                 \   |

                             \ |                   \ |

                               6                     12
```

Figure 2.X2 Triangles with adjacency. The vertices connected with solid lines belong to the main primitive; the vertices connected by dashed lines are the adjacent vertices that may be used in a geometry shader.

Triangles with Adjacency

Triangles with adjacency are similar to separate triangles, except that each triangle edge has an adjacent vertex that can be accessed by a geometry shader (Section 2.15). If a geometry shader is not active, the "adjacent" vertices are ignored.

The 6i + 1st, 6i + 3rd, and 6i + 5th vertices (in that order) determine a triangle for each i = 0, 1, ..., n-1, where there are 6n+k vertices between the Begin and End. k is either 0, 1, 2, 3, 4, or 5; if k is non-zero, the final k vertices are ignored. For triangle i, the i + 2nd, i + 4th, and i + 6th vertices are considered adjacent to edges from the i + 1st to the i + 3rd, from the i + 3rd to the i + 5th, and from the i + 5th to the i + 1st vertices, respectively. See Figure 2.X2.

Triangles with adjacency are generated by calling Begin with the argument value TRIANGLES_ADJACENCY_EXT.

```

Figure 2.X3 Triangle strips with adjacency. The vertices connected with solid lines belong to the main primitives; the vertices connected by dashed lines are the adjacent vertices that may be used in a geometry shader.

Triangle Strips with Adjacency

Triangle strips with adjacency are similar to triangle strips, except that each line triangle edge has an adjacent vertex that can be accessed by a geometry shader (Section 2.15). If a geometry shader is not active, the "adjacent" vertices are ignored.

In triangle strips with adjacency, n triangles are drawn using 2 * (n+2) + k vertices between the Begin and End. k is either 0 or 1; if k is 1, the final vertex is ignored. If fewer than 6 vertices are specified between the Begin and End, the entire primitive is ignored. Table 2.X1 describes the vertices and order used to draw each triangle, and which vertices are considered adjacent to each edge of the triangle. See Figure 2.X3.

(add table)

	primitive vertices			adjacent vertices		
primitive	1st	2nd	3rd	1/2	2/3	3/1
only (i==0, n==1)	1	3	5	2	6	4
first (i==0)	1	3	5	2	7	4
middle (i odd)	2i+3	2i+1	2i+5	2i-1	2i+4	2i+7
middle (i even)	2i+1	2i+3	2i+5	2i-1	2i+7	2i+4
last (i==n-1, i odd)	2i+3	2i+1	2i+5	2i-1	2i+4	2i+6
last (i==n-1, i even)	2i+1	2i+3	2i+5	2i-1	2i+6	2i+4

Table 2.X1: Triangles generated by triangle strips with adjacency. Each triangle is drawn using the vertices in the "1st", "2nd", and "3rd" columns under "primitive vertices", in that order. The vertices in the "1/2", "2/3", and "3/1" columns under "adjacent vertices" are considered adjacent to the edges from the first to the second, from the second to the third, and from the third to the first vertex of the triangle, respectively. The six rows correspond to the six cases: the first and only triangle (i=0, n=1), the first triangle of several (i=0, n>0), "odd" middle triangles (i=1,3,5...), "even" middle triangles (i=2,4,6,...), and special cases for the last triangle inside the Begin/End, when i is either even or odd. For the purposes of this table, the first vertex specified after Begin is numbered "1" and the first triangle is numbered "0".

Triangle strips with adjacency are generated by calling Begin with the argument value TRIANGLE_STRIP_ADJACENCY_EXT.

Modify Section 2.14.1, Lighting (p. 59)

(modify fourth paragraph, p. 63) Additionally, vertex and geometry shaders can operate in two-sided color mode, which is enabled and disabled by calling Enable or Disable with the symbolic value VERTEX_PROGRAM_TWO_SIDE. When a vertex or geometry shader is active, the shaders can write front and back color values to the gl_FrontColor, gl_BackColor, gl_FrontSecondaryColor and gl_BackSecondaryColor outputs. When a vertex or geometry shader is active and two-sided color mode is enabled, the GL chooses between front and back colors, as described below. If two-sided color mode is disabled, the front color output is always selected.

Modify Section 2.15.2 Program Objects, p. 73

Change the first paragraph on p. 74 as follows:

Program objects are empty when they are created. Default values for program object parameters are discussed in section 2.15.5, Required State. A non-zero name that can be used to reference the program object is returned.

Change the language below the LinkProgram command on p. 74 as follows:

... Linking can fail for a variety of reasons as specified in the OpenGL Shading Language Specification. Linking will also fail if one or more of the shader objects, attached to <program> are not compiled successfully, or if more active uniform or active sampler variables are used in <program> than allowed (see sections 2.15.3 and 2.16.3). Linking will also fail if the program object contains objects to form a geometry shader (see section 2.16), but no objects to form a vertex shader or if the program object contains objects to form a geometry shader, and the value of GEOMETRY_VERTICES_OUT_EXT is zero. If LinkProgram failed, ..

Add the following paragraphs above the description of DeleteProgram, p. 75:

To set a program object parameter, call

```
    void ProgramParameteriEXT(uint program, enum pname, int value)
```

<param> identifies which parameter to set for <program>. <value> holds the value being set. Legal values for <param> and <value> are discussed in section 2.16.

Modify Section 2.15.3, Shader Variables, p. 75

Modify the first paragraph of section 'Varying Variables' p. 83 as follows:

A vertex shader may define one or more varying variables (see the OpenGL Shading Language specification). Varying variables are outputs of a vertex shader. They are either used as the mechanism to communicate values to a geometry shader, if one is active, or to communicate values to the fragment shader. The OpenGL Shading Language specification also defines a set of built-in varying variables that vertex shaders can write to (see section 7.6 of the OpenGL Shading Language Specification). These variables can also be used to communicate values to a geometry shader, if one is active, or to communicate values to the fragment shader and to the fixed-function processing that occurs after vertex shading.

If a geometry shader is not active, the values of all varying variables, including built-in variables, are expected to be interpolated across the primitive being rendered, unless flat shaded. The number of interpolators available for processing varying variables is given by the implementation-dependent constant MAX_VARYING_COMPONENTS_EXT. This value represents the number of individual components that can be interpolated; varying variables declared as vectors, matrices, and arrays will all consume multiple interpolators. When a program is linked, all components of any varying variable written by a vertex shader, or read by a fragment shader, will count against this limit. The transformed vertex position (gl_Position) does not count against this limit. A program whose vertex and/or fragment shaders access more than MAX_VARYING_COMPONENTS_EXT components worth of varying variables may fail to link, unless device-dependent optimizations are able to make the program fit within available hardware resources.

Note that the two values MAX_VARYING_FLOATS and MAX_VARYING_COMPONENTS_EXT are aliases of each other. The use of MAX_VARYING_FLOATS however is discouraged; varying variables can be declared as integers as well.

If a geometry shader is active, the values of varying variables are collected by the primitive assembly stage and passed on to the geometry shader once enough data for one primitive has been collected (see also section 2.16). The OpenGL Shading Language specification also defines a set of built-in varying and built-in special variables that vertex shaders can write to (see sections 7.1 and 7.6 of the OpenGL Shading Language Specification). These variables are also collected and passed on to the geometry shader once enough data has been collected. The number of components of varying and special variables that can be collected per vertex by the primitive assembly stage is given by the implementation dependent constant MAX_VERTEX_VARYING_COMPONENTS_EXT. This value represents the number of individual components that can be collected; varying variables declared as vectors, matrices, and arrays will all consume multiple components. When a program is linked, all components of any varying variable written by a vertex shader, or read by a geometry shader, will count against this limit. A program whose vertex and/or geometry shaders access more than MAX_VERTEX_VARYING_COMPONENTS_EXT components worth of varying variables may fail to link, unless device-dependent optimizations are able to make the program fit within available hardware resources.

Modify Section 2.15.4 Shader Execution, p. 84

Change the following sentence:

"The following operations are applied to vertex values that are the result of executing the vertex shader:"

As follows:

If no geometry shader (see section 2.16) is present in the program object, the following operations are applied to vertex values that are the result of executing the vertex shader:

[bulleted list of operations]

On page 85, below the list of bullets, add the following:

If a geometry shader is present in the program object, geometry shading (section 2.16) is applied to vertex values that are the result of executing the vertex shader.

Modify the first paragraph of the section 'Texture Access', p. 85, as follows:

Vertex shaders have the ability to do a lookup into a texture map, if supported by the GL implementation. The maximum number of texture image units available to a vertex shader is MAX_VERTEX_TEXTURE_IMAGE_UNITS; a maximum number of zero indicates that the GL implementation does not support texture accesses in vertex shaders. The vertex shader, geometry shader, if exists, and fragment processing combined cannot use more than MAX_COMBINED_TEXTURE_IMAGE_UNITS texture image units. If the vertex shader, geometry shader and the fragment processing stage access the same texture image unit, then that counts as using three texture image units against the MAX_COMBINED_TEXTURE_IMAGE_UNITS limit.

Modify Section 2.15.5, Required State, p. 88

Add the following bullets to the state required per program object:

* One integer to store the value of GEOMETRY_VERTICES_OUT_EXT, initially zero.

* One integer to store the value of GEOMETRY_INPUT_TYPE_EXT, initially set to TRIANGLES.

* One integer to store the value of GEOMETRY_OUTPUT_TYPE_EXT, initially set to TRIANGLE_STRIP.

Insert New Section 2.16, Geometry Shaders after p. 89

After vertices are processed, they are arranged into primitives, as described in section 2.6.1 (Begin/End Objects). This section described a new pipeline stage that processes those primitives. A geometry shader defines the operations that are performed in this new pipeline stage. A geometry shader is an array of strings containing source code. The source code language used is described in the OpenGL Shading Language specification. A geometry shader operates on a single primitive at a time and emits one or more output primitives, all of the same type, which are then processed like an equivalent OpenGL primitive specified by the application. The original primitive is discarded after the geometry shader completes. The inputs available to a geometry shader are the transformed attributes of all the vertices that belong to the primitive. Additional "adjacency" primitives are available which also make the transformed attributes of neighboring vertices available to the shader. The results of the shader are a new set of transformed vertices, arranged into primitives by the shader.

This new geometry shader pipeline stage is inserted after primitive assembly, right before color clamping (section 2.14.6), flat shading (section 2.14.7) and clipping (sections 2.12 and 2.14.8).

A geometry shader only applies when the GL is in RGB mode. Its operation in color index mode is undefined.

Geometry shaders are created as described in section 2.15.1 using a type parameter of GEOMETRY_SHADER_EXT. They are attached to and used in program objects as described in section 2.15.2. When the program object currently in use includes a geometry shader, its geometry shader is considered active, and is used to process primitives. If the program object has no geometry shader, or no program object is in use, this new primitive processing pipeline stage is bypassed.

A program object that includes a geometry shader must also include a vertex shader; otherwise a link error will occur.

Section 2.16.1, Geometry shader Input Primitives

A geometry shader can operate on one of five input primitive types. Depending on the input primitive type, one to six input vertices are available when the shader is executed. Each input primitive type supports a subset of the primitives provided by the GL. If a geometry shader is active, Begin, or any function that implicitly calls Begin, will produce an INVALID_OPERATION error if the <mode> parameter is incompatible with the input primitive type of the currently active program object, as discussed below.

The input primitive type is a parameter of the program object, and must be set before linking by calling ProgramParameteriEXT with <pname> set to GEOMETRY_INPUT_TYPE_EXT and <value> set to one of POINTS, LINES, LINES_ADJACENCY_EXT, TRIANGLES or TRIANGLES_ADJACENCY_EXT. This setting will not be in effect until the next time LinkProgram has been called successfully. Note that queries of GEOMETRY_INPUT_TYPE_EXT will return the last value set. This is not necessarily the value used to generate the executable code in the program object. After a program object has been created it will have a default value for GEOMETRY_INPUT_TYPE_EXT, as discussed in section 2.15.5, Required State.

Note that a geometry shader that accesses more input vertices than are available for a given input primitive type can be successfully compiled, because the input primitive type is not part of the shader object. However, a program object, containing a shader object that access more input vertices than are available for the input primitive type of the program object, will not link.

The supported input primitive types are:

Points (POINTS)

Geometry shaders that operate on points are valid only for the POINTS primitive type. There is only a single vertex available for each geometry shader invocation.

Lines (LINES)

Geometry shaders that operate on line segments are valid only for the LINES, LINE_STRIP, and LINE_LOOP primitive types. There are two vertices available for each geometry shader invocation. The first vertex refers to the vertex at the beginning of the line segment and the second vertex refers to the vertex at the end of the line segment. See also section 2.16.4.

Lines with Adjacency (LINES_ADJACENCY_EXT)

Geometry shaders that operate on line segments with adjacent vertices are valid only for the LINES_ADJACENCY_EXT and LINE_STRIP_ADJACENCY_EXT primitive types. There are four vertices available for each program invocation. The second vertex refers to attributes of the vertex at the beginning of the line segment and the third vertex refers to the vertex at the end of the line segment. The first and fourth vertices refer to the vertices adjacent to the beginning and end of the line segment, respectively.

Triangles (TRIANGLES)

Geometry shaders that operate on triangles are valid for the TRIANGLES, TRIANGLE_STRIP and TRIANGLE_FAN primitive types.

There are three vertices available for each program invocation. The first, second and third vertices refer to attributes of the first, second and third vertex of the triangle, respectively.

Triangles with Adjacency (TRIANGLES_ADJACENCY_EXT)

Geometry shaders that operate on triangles with adjacent vertices are valid for the TRIANGLES_ADJACENCY_EXT and TRIANGLE_STRIP_ADJACENCY_EXT primitive types. There are six vertices available for each program invocation. The first, third and fifth vertices refer to attributes of the first, second and third vertex of the triangle, respectively. The second, fourth and sixth vertices refer to attributes of the vertices adjacent to the edges from the first to the second vertex, from the second to the third vertex, and from the third to the first vertex, respectively.

Section 2.16.2, Geometry Shader Output Primitives

A geometry shader can generate primitives of one of three types. The supported output primitive types are points (POINTS), line strips (LINE_STRIP), and triangle strips (TRIANGLE_STRIP). The vertices output by the geometry shader are decomposed into points, lines, or triangles based on the output primitive type in the manner described in section 2.6.1. The resulting primitives are then further processed as shown in figure 2.16.xxx. If the number of vertices emitted by the geometry shader is not sufficient to produce a single primitive, nothing is drawn.

The output primitive type is a parameter of the program object, and can be set by calling ProgramParameteriEXT with <pname> set to GEOMETRY_OUTPUT_TYPE_EXT and <value> set to one of POINTS, LINE_STRIP or TRIANGLE_STRIP. This setting will not be in effect until the next time LinkProgram has been called successfully. Note that queries of GEOMETRY_OUTPUT_TYPE_EXT will return the last value set; which is not necessarily the value used to generate the executable code in the program object. After a program object has been created it will have a default value for GEOMETRY_OUTPUT_TYPE_EXT, as discussed in section 2.15.5, Required State. .

Section 2.16.3 Geometry Shader Variables

Geometry shaders can access uniforms belonging to the current program object. The amount of storage available for geometry shader uniform variables is specified by the implementation dependent constant MAX_GEOMETRY_UNIFORM_COMPONENTS_EXT. This value represents the number of individual floating-point, integer, or Boolean values that can be held in uniform variable storage for a geometry shader. A link error will be generated if an attempt is made to utilize more than the space available for geometry shader uniform variables. Uniforms are manipulated as described in section 2.15.3. Geometry shaders also have access to samplers, to perform texturing operations, as described in sections 2.15.3 and 3.8.

Geometry shaders can access the transformed attributes of all vertices for its input primitive type through input varying variables. A vertex shader, writing to output varying variables, generates the values of these input varying variables. This includes values for built-in as well as user-defined varying variables. Values for any varying variables that are not written by a vertex shader are undefined. Additionally, a geometry shader has access to a built-in variable that holds the ID of the current primitive. This ID is generated by the primitive assembly stage that sits in between the vertex and geometry shader.

Additionally, geometry shaders can write to one, or more, varying variables for each primitive it outputs. These values are optionally flat shaded (using the OpenGL Shading Language varying qualifier "flat") and clipped, then the clipped values interpolated across the primitive (if not flat shaded). The results of these interpolations are available to a fragment shader, if one is active. Furthermore, geometry shaders can write to a set of built- in varying variables, defined in the OpenGL Shading Language, that correspond to the values required for the fixed-function processing that occurs after geometry processing.

Section 2.16.4, Geometry Shader Execution Environment

If a successfully linked program object that contains a geometry shader is made current by calling UseProgram, the executable version of the geometry shader is used to process primitives resulting from the primitive assembly stage.

The following operations are applied to the primitives that are the result of executing a geometry shader:

* color clamping or masking (section 2.14.6),
* flat shading (section 2.14.7),
* clipping, including client-defined clip planes (section 2.12),
* front face determination (section 2.14.1),
* color and associated data clipping (section 2.14.8),
* perspective division on clip coordinates (section 2.11),
* final color processing (section 2.14.9), and
* viewport transformation, including depth-range scaling (section 2.11.1).

There are several special considerations for geometry shader execution described in the following sections.

Texture Access

Geometry shaders have the ability to do a lookup into a texture map, if supported by the GL implementation. The maximum number of texture image units available to a geometry shader is MAX_GEOMETRY_TEXTURE_IMAGE_UNITS_EXT; a maximum number of zero indicates that the GL implementation does not support texture accesses in geometry shaders.

The vertex shader, geometry shader and fragment processing combined cannot use more than MAX_COMBINED_TEXTURE_IMAGE_UNITS texture image units. If the vertex shader, geometry shader and the fragment processing stage access the same texture image unit, then that counts as using three texture image units against the MAX_COMBINED_TEXTURE_IMAGE_UNITS limit.

When a texture lookup is performed in a geometry shader, the filtered texture value tau is computed in the manner described in sections 3.8.8 and 3.8.9, and converted to a texture source color Cs according to table 3.21 (section 3.8.13). A four component vector (Rs,Gs,Bs,As) is returned to the geometry shader. In a geometry shader it is not possible to perform automatic level-of- detail calculations using partial derivatives of the texture coordinates with respect to window coordinates as described in section 3.8.8. Hence, there is no automatic selection of an image array level. Minification or magnification of a texture map is controlled by a level-of-detail value optionally passed as an argument in the texture lookup functions. If the texture lookup function supplies an explicit level-of-detail value lambda, then the pre-bias level-of-detail value LAMBDAbase(x, y) = lambda (replacing equation 3.18). If the texture lookup function does not supply an explicit level-of-detail value, then LAMBDAbase(x, y) = 0. The scale factor Rho(x, y) and its approximation function f(x, y) (see equation 3.21) are ignored.

Texture lookups involving textures with depth component data can either return the depth data directly or return the results of a comparison with the R value (see section 3.8.14) used to perform the lookup. The comparison operation is requested in the shader by using any of the shadow sampler and in the texture using the TEXTURE COMPARE MODE parameter. These requests must be consistent; the results of a texture lookup are undefined if:

* the sampler used in a texture lookup function is not one of the shadow sampler types, and the texture object's internal format is DEPTH COMPONENT, and the TEXTURE COMPARE MODE is not NONE;

* the sampler used in a texture lookup function is one of the shadow sampler types, and the texture object's internal format is DEPTH COMPONENT, and the TEXTURE COMPARE MODE is NONE; or

* the sampler used in a texture lookup function is one of the shadow sampler types, and the texture object's internal format is not DEPTH COMPONENT.

If a geometry shader uses a sampler where the associated texture object is not complete as defined in section 3.8.10, the texture image unit will return (R,G,B,A) = (0, 0, 0, 1).

Geometry Shader Inputs

The OpenGL Shading Language specification describes the set of built-in variables that are available as inputs to the geometry shader. This set receives the values from the equivalent built-in output variables written by the vertex shader. These built-in variables are arrays; each element in the array holds the value for a specific vertex of the input primitive. The length of each array depends on the value of the input primitive type, as determined by the program object value GEOMETRY_INPUT_TYPE_EXT, and is set by the GL during link. Each built-in variable is a one-dimensional array, except for the built-in texture coordinate variable, which is a two- dimensional array. The vertex shader built-in output gl_TexCoord[] is a one-dimensional array. Therefore, the geometry shader equivalent input variable gl_TexCoordIn[][] becomes a two-dimensional array. See the OpenGL Shading Language Specification, sections 4.3.6 and 7.6 for more information.

The built-in varying variables gl_FrontColorIn[], gl_BackColorIn[], gl_FrontSecondaryColorIn[] and gl_BackSecondaryColorIn[] hold the per-vertex front and back colors of the primary and secondary colors, as written by the vertex shader to its equivalent built-in output variables.

The built-in varying variable gl_TexCoordIn[][] holds the per- vertex values of the array of texture coordinates, as written by the vertex shader to its built-in output array gl_TexCoord[].

The built-in varying variable gl_FogFragCoordIn[] holds the per- vertex fog coordinate, as written by the vertex shader to its built- in output variable gl_FogFragCoord.

The built-in varying variable gl_PositionIn[] holds the per-vertex position, as written by the vertex shader to its output variable gl_Position. Note that writing to gl_Position from either the vertex or fragment shader is optional. See also section 7.1 "Vertex and Geometry Shader Special Variables" of the OpenGL Shading Language specification.

The built-in varying variable gl_ClipVertexIn[] holds the per-vertex position in clip coordinates, as written by the vertex shader to its output variable gl_ClipVertex.

The built-in varying variable gl_PointSizeIn[] holds the per-vertex point size written by the vertex shader to its built-in output varying variable gl_PointSize. If the vertex shader does not write gl_PointSize, the value of gl_PointSizeIn[] is undefined, regardless of the value of the enable VERTEX_PROGRAM_POINT_SIZE.

The built-in special variable gl_PrimitiveIDIn is not an array and has no vertex shader equivalent. It is filled with the number of primitives processed since the last time Begin was called (directly or indirectly via vertex array functions). The first primitive generated after a Begin is numbered zero, and the primitive ID counter is incremented after every individual point, line, or triangle primitive is processed. For triangles drawn in point or line mode, the primitive ID counter is incremented only once, even though multiple points or lines may be drawn. Restarting a primitive topology using the primitive restart index has no effect on the primitive ID counter.

Similarly to the built-in varying variables, user-defined input varying variables need to be declared as arrays. Declaring a size is optional. If no size is specified, it will be inferred by the linker from the input primitive type. If a size is specified, it has to be of the size matching the number of vertices of the input primitive type, otherwise a link error will occur. The built-in variable gl_VerticesIn, if so desired, can be used to size the array correctly for each input primitive type. User-defined varying variables can be declared as arrays in the vertex shader. This means that those, on input to the geometry shader, must be declared as two-dimensional arrays. See sections 4.3.6 and 7.6 of the OpenGL Shading Language Specification for more information.

Using any of the built-in or user-defined input varying variables can count against the limit MAX_VERTEX_VARYING_COMPONENTS_EXT as discussed in section 2.15.3.

Geometry Shader outputs

A geometry shader is limited in the number of vertices it may emit per invocation. The maximum number of vertices a geometry shader can possibly emit needs to be set as a parameter of the program object that contains the geometry shader. To do so, call ProgramParameteriEXT with <pname> set to GEOMETRY_VERTICES_OUT_EXT and <value> set to the maximum number of vertices the geometry shader will emit in one invocation. This setting will not be guaranteed to be in effect until the next time LinkProgram has been called successfully. If a geometry shader, in one invocation, emits more vertices than the value GEOMETRY_VERTICES_OUT_EXT, these emits may have no effect.

There are two implementation-dependent limits on the value of GEOMETRY_VERTICES_OUT_EXT. First, the error INVALID_VALUE will be generated by ProgramParameteriEXT if the number of vertices specified exceeds the value of MAX_GEOMETRY_OUTPUT_VERTICES_EXT. Second, the product of the total number of vertices and the sum of all components of all active varying variables may not exceed the value of MAX_GEOMETRY_TOTAL_OUTPUT_COMPONENTS_EXT. LinkProgram will fail if it determines that the total component limit would be violated.

A geometry shader can write to built-in as well as user-defined varying variables. These values are expected to be interpolated across the primitive it outputs, unless they are specified to be flat shaded. In order to seamlessly be able to insert or remove a geometry shader from a program object, the rules, names and types of the output built-in varying variables and user-defined varying variables are the same as for the vertex shader. Refer to section 2.15.3 and the OpenGL Shading Language specification sections 4.3.6, 7.1 and 7.6 for more detail.

The built-in output variables gl_FrontColor, gl_BackColor, gl_FrontSecondaryColor, and gl_BackSecondaryColor hold the front and back colors for the primary and secondary colors for the current vertex.

The built-in output variable gl_TexCoord[] is an array and holds the set of texture coordinates for the current vertex.

The built-in output variable gl_FogFragCoord is used as the "c" value, as described in section 3.10 "Fog" of the OpenGL 2.0 specification.

The built-in special variable gl_Position is intended to hold the homogeneous vertex position. Writing gl_Position is optional.

The built-in special variable gl_ClipVertex holds the vertex coordinate used in the clipping stage, as described in section 2.12 "Clipping" of the OpenGL 2.0 specification.

The built-in special variable gl_PointSize, if written, holds the size of the point to be rasterized, measured in pixels.

Additionally, a geometry shader can write to the built-in special variables gl_PrimitiveID and gl_Layer, whereas a vertex shader cannot. The built-in gl_PrimitiveID provides a single integer that serves as a primitive identifier. This written primitive ID is available to fragment shaders. If a fragment shader using primitive IDs is active and a geometry shader is also active, the geometry shader must write to gl_PrimitiveID or the primitive ID number is undefined. The built-in variable gl_Layer is used in layered rendering, and discussed in the next section.

The number of components available for varying variables is given by the implementation-dependent constant MAX_GEOMETRY_VARYING_COMPONENTS_EXT. This value represents the number of individual components of a varying variable; varying variables declared as vectors, matrices, and arrays will all consume multiple components. When a program is linked, all components of any varying variable written by a geometry shader, or read by a fragment shader, will count against this limit. The transformed vertex position (gl_Position) does not count against this limit. A program whose geometry and/or fragment shaders access more than MAX_GEOMETRY_VARYING_COMPONENTS_EXT worth of varying variable components may fail to link, unless device-dependent optimizations are able to make the program fit within available hardware resources.

Layered rendering

Geometry shaders can be used to render to one of several different layers of cube map textures, three-dimensional textures, plus one- dimensional and two-dimensional texture arrays. This functionality allows an application to bind an entire "complex" texture to a framebuffer object, and render primitives to arbitrary layers computed at run time. For example, this mechanism can be used to project and render a scene onto all six faces of a cubemap texture in one pass. The layer to render to is specified by writing to the built-in output variable gl_layer. Layered rendering requires the use of framebuffer objects. Refer to the section 'Dependencies on EXT_framebuffer_object' for details.

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

Modify Section 3.3, Points (p. 95)

(replace all Section 3.3 text on p. 95)

A point is drawn by generating a set of fragments in the shape of a square or circle centered around the vertex of the point. Each vertex has an associated point size that controls the size of that square or circle.

If no vertex or geometry shader is active, the size of the point is controlled by

```
      void PointSize(float size);
```

<size> specifies the requested size of a point. The default value is 1.0. A value less than or equal to zero results in the error INVALID_VALUE.

The requested point size is multiplied with a distance attenuation factor, clamped to a specified point size range, and further clamped to the implementation-dependent point size range to produce the derived point size:

```
       derived size = clamp(size * sqrt(1/(a+b*d+c*d^2)))
```

where d is the eye-coordinate distance from the eye, (0,0,0,1) in eye coordinates, to the vertex, and a, b, and c are distance attenuation function coefficients.

If a vertex or geometry shader is active, the derived size depends on the per-vertex point size mode enable. Per-vertex point size mode is enabled or disabled by calling Enable or Disable with the symbolic value PROGRAM_POINT_SIZE_EXT. If per-vertex point size is enabled and a geometry shader is active, the derived point size is taken from the (potentially clipped) point size variable gl_PointSize written by the geometry shader. If per-vertex point size is enabled and no geometry shader is active, the derived point size is taken from the (potentially clipped) point size variable gl_PointSize written by the vertex shader. If per-vertex point size is disabled and a geometry and/or vertex shader is active, the derived point size is taken from the <size> value provided to PointSize, with no distance attenuation applied. In all cases, the derived point size is clamped to the implementation-dependent point size range.

If multisampling is not enabled, the derived size is passed on to rasterization as the point width. ...

Modify section 3.10 "Fog", p. 191

Modify the third paragraph of this section as follows.

If a vertex or geometry shader is active, or if the fog source, as defined below, is FOG_COORD, then c is the interpolated value of the fog coordinate for this fragment. Otherwise, ...

Additions to Chapter 4 of the OpenGL 2.0 Specification (Per-Fragment Operations and the Frame Buffer)

None.

Additions to Chapter 5 of the OpenGL 2.0 Specification (Special Functions)

Change section 5.4 Display Lists, p. 237

Add the command ProgramParameteriEXT to the list of commands that are not compiled into a display list, but executed immediately, under "Program and Shader Objects", p. 241

Additions to Chapter 6 of the OpenGL 2.0 Specification (State and State Requests)

Modify section 6.1.14, Shader and Program Objects, p. 256

Add to the second paragraph on p. 257:

... if <shader> is a fragment shader object, and GEOMETRY_SHADER_EXT is returned if <shader> is a geometry shader object.

Add to the end of the description of GetProgramiv, p. 257:

If <pname> is GEOMETRY_VERTICES_OUT_EXT, the current value of the maximum number of vertices the geometry shader will output is returned. If <pname> is GEOMETRY_INPUT_TYPE_EXT, the current geometry shader input type is returned and can be one of POINTS, LINES, LINES_ADJACENCY_EXT, TRIANGLES or TRIANGLES_ADJACENCY_EXT. If <pname> is GEOMETRY_OUTPUT_TYPE_EXT, the current geometry shader output type is returned and can be one of POINTS, LINE_STRIP or TRIANGLE_STRIP.

Additions to Appendix A of the OpenGL 2.0 Specification (Invariance)

None.

Additions to the AGL/GLX/WGL Specifications

None.

Dependencies on NV_primitive_restart

The spec describes the behavior that primitive restart does not affect the primitive ID counter gl_PrimitiveIDIn. If NV_primitive_restart is not supported, references to that extension in the discussion of the primitive ID should be removed.

Dependencies on EXT_framebuffer_object

If EXT_framebuffer_object (or similar functionality) is not supported, the gl_Layer output has no effect. "FramebufferTextureEXT" and "FramebufferTextureLayerEXT" should be removed from "New Procedures and Functions", and FRAMEBUFFER_ATTACHMENT_LAYERED_EXT, FRAMEBUFFER_INCOMPLETE_LAYER_TARGETS_EXT, and FRAMEBUFFER_INCOMPLETE_LAYER_COUNT_EXT should be removed from "New Tokens".

Otherwise, this extension modifies EXT_framebuffer_object to add the notion of layered framebuffer attachments and framebuffers that can be used in conjunction with geometry shaders to allow programs to direct primitives to a face of a cube map or layer of a three-dimensional texture or one- or two-dimensional array texture. The layer used for rendering can be selected by the geometry shader at run time.

(insert before the end of Section 4.4.2, Attaching Images to Framebuffer Objects)

There are several types of framebuffer-attachable images:

* the image of a renderbuffer object, which is always two-dimensional,

* a single level of a one-dimensional texture, which is treated as a two-dimensional image with a height of one,

* a single level of a two-dimensional or rectangle texture,

* a single face of a cube map texture level, which is treated as a two-dimensional image, or

* a single layer of a one- or two-dimensional array texture or three-dimensional texture, which is treated as a two-dimensional image.

Additionally, an entire level of a three-dimensional texture, cube map texture, or one- or two-dimensional array texture can be attached to an attachment point. Such attachments are treated as an array of two-dimensional images, arranged in layers, and the corresponding attachment point is considered to be layered.

(replace section 4.4.2.3, "Attaching Texture Images to a Framebuffer")

GL supports copying the rendered contents of the framebuffer into the images of a texture object through the use of the routines CopyTexImage{1D|2D}, and CopyTexSubImage{1D|2D|3D}. Additionally, GL supports rendering directly into the images of a texture object.

To render directly into a texture image, a specified level of a texture object can be attached as one of the logical buffers of the currently bound framebuffer object by calling:

```
  void FramebufferTextureEXT(enum target, enum attachment,
                             uint texture, int level);
```

<target> must be FRAMEBUFFER_EXT. <attachment> must be one of the attachment points of the framebuffer listed in table 1.nnn.

If <texture> is zero, any image or array of images attached to the attachment point named by <attachment> is detached, and the state of the attachment point is reset to its initial values. <level> is ignored if <texture> is zero.

If <texture> is non-zero, FramebufferTextureEXT attaches level <level> of the texture object named <texture> to the framebuffer attachment point named by <attachment>. The error INVALID_VALUE is generated if <texture> is not the name of a texture object, or if <level> is not a supported texture level number for textures of the type corresponding to <target>.

The error INVALID_OPERATION is generated if <texture> is the name of a buffer texture.

If <texture> is the name of a three-dimensional texture, cube map texture, or one- or two-dimensional array texture, the texture level attached to the framebuffer attachment point is an array of images, and the framebuffer attachment is considered layered.

The command

```
  void FramebufferTextureLayerEXT(enum target, enum attachment,
                                  uint texture, int level, int layer);
```

operates like FramebufferTextureEXT, except that only a single layer of the texture level, numbered <layer>, is attached to the attachment point. If <texture> is non-zero, the error INVALID_VALUE is generated if <layer> is negative, or if <texture> is not the name of a texture object. The error INVALID_OPERATION is generated unless <texture> is zero or the name of a three-dimensional or one- or two-dimensional array texture.

The command

```
  void FramebufferTextureFaceEXT(enum target, enum attachment,
                                 uint texture, int level, enum face);
```

operates like FramebufferTextureEXT, except that only a single face of a cube map texture, given by <face>, is attached to the attachment point. <face> is one of TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_Z. If <texture> is non-zero, the error INVALID_VALUE is generated if <texture> is not the name of a texture object. The error INVALID_OPERATION is generated unless <texture> is zero or the name of a cube map texture.

The command

```
  void FramebufferTexture1DEXT(enum target, enum attachment,
                               enum textarget, uint texture, int level);
```

operates identically to FramebufferTextureEXT, except for two additional restrictions. If <texture> is non-zero, the error INVALID_ENUM is generated if <textarget> is not TEXTURE_1D and the error INVALID_OPERATION is generated unless <texture> is the name of a one-dimensional texture.

The command

```
  void FramebufferTexture2DEXT(enum target, enum attachment,
                               enum textarget, uint texture, int level);
```

operates similarly to FramebufferTextureEXT. If <textarget> is TEXTURE_2D or TEXTURE_RECTANGLE_ARB, <texture> must be zero or the name of a two-dimensional or rectangle texture. If <textarget> is TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, or TEXTURE_CUBE_MAP_NEGATIVE_Z, <texture> must be zero or the name of a cube map texture. For cube map textures, only the single face of the cube map texture level given by <textarget> is attached. The error INVALID_ENUM is generated if <texture> is not zero and <textarget> is not one of the values enumerated above. The error INVALID_OPERATION is generated if <texture> is the name of a texture whose type does not match the texture type required by <textarget>.

The command

```
  void FramebufferTexture3DEXT(enum target, enum attachment,
                               enum textarget, uint texture,
                               int level, int zoffset);
```

behaves identically to FramebufferTextureLayerEXT, with the <layer> parameter set to the value of <zoffset>. The error INVALID_ENUM is generated if <textarget> is not TEXTURE_3D. The error INVALID_OPERATION is generated unless <texture> is zero or the name of a three-dimensional texture.

For all FramebufferTexture commands, if <texture> is non-zero and the command does not result in an error, the framebuffer attachment state corresponding to <attachment> is updated based on the new attachment. FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT is set to TEXTURE, FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT is set to <texture>, and FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL is set to <level>. FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_FACE is set to <textarget> if FramebufferTexture2DEXT is called and <texture> is the name of a cubemap texture; otherwise, it is set to TEXTURE_CUBE_MAP_POSITIVE_X. FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER_EXT is set to <layer> or <zoffset> if FramebufferTextureLayerEXT or FramebufferTexture3DEXT is called; otherwise, it is set to zero. FRAMEBUFFER_ATTACHMENT_LAYERED_EXT is set to TRUE if FramebufferTextureEXT is called and <texture> is the name of a three-dimensional texture, cube map texture, or one- or two-dimensional array texture; otherwise it is set to FALSE.

(modify Section 4.4.4.1, Framebuffer Attachment Completeness -- add to the conditions necessary for attachment completeness)

The framebuffer attachment point <attachment> is said to be "framebuffer attachment complete" if ...:

* If FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT is TEXTURE and FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT names a three-dimensional texture, FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER_EXT must be smaller than the depth of the texture.

* If FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT is TEXTURE and FRAMEBUFFER_ATTACHMENT_OBJECT_NAME_EXT names a one- or two-dimensional array texture, FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER_EXT must be smaller than the number of layers in the texture.

(modify section 4.4.4.2, Framebuffer Completeness -- add to the list of conditions necessary for completeness)

* If any framebuffer attachment is layered, all populated attachments must be layered. Additionally, all populated color attachments must be from textures of the same target (i.e., three-dimensional, cube map, or one- or two-dimensional array textures).
  { FRAMEBUFFER_INCOMPLETE_LAYER_TARGETS_EXT }

* If any framebuffer attachment is layered, all attachments must have the same layer count. For three-dimensional textures, the layer count is the depth of the attached volume. For cube map textures, the layer count is always six. For one- and two-dimensional array textures, the layer count is simply the number of layers in the array texture. { FRAMEBUFFER_INCOMPLETE_LAYER_COUNT_EXT }

The enum in { brackets } after each clause of the framebuffer completeness rules specifies the return value of CheckFramebufferStatusEXT (see below) that is generated when that clause is violated. ...

(add section 4.4.7, Layered Framebuffers)

A framebuffer is considered to be layered if it is complete and all of its populated attachments are layered. When rendering to a layered framebuffer, each fragment generated by the GL is assigned a layer number. The layer number for a fragment is zero if

* the fragment is generated by DrawPixels, CopyPixels, or Bitmap,

* geometry shaders are disabled, or

* the current geometry shader does not contain an instruction that statically assigns a value to the built-in output variable gl_Layer.

Otherwise, the layer for each point, line, or triangle emitted by the geometry shader is taken from the layer output of one of the vertices of the primitive. The vertex used is implementation-dependent. To get defined results, all vertices of each primitive emitted should set the same value for gl_Layer. Since the EndPrimitive() built-in function starts a new output primitive, defined results can be achieved if EndPrimitive() is called between two vertices emitted with different layer numbers. A layer number written by a geometry shader has no effect if the framebuffer is not layered.

When fragments are written to a layered framebuffer, the fragment's layer number selects an image from the array of images at each attachment point from which to obtain the destination R, G, B, A values for blending (Section 4.1.8) and to which to write the final color values for that attachment. If the fragment's layer number is negative or greater than the number of layers attached, the effects of the fragment on the framebuffer contents are undefined.

When the Clear command is used to clear a layered framebuffer attachment, all layers of the attachment are cleared.

When commands such as ReadPixels or CopyPixels read from a layered framebuffer, the image at layer zero of the selected attachment is always used to obtain pixel values.

When cube map texture levels are attached to a layered framebuffer, there are six layers attached, numbered zero through five. Each layer number is mapped to a cube map face, as indicated in Table X.4.

layer number	cube map face
0	TEXTURE_CUBE_MAP_POSITIVE_X
1	TEXTURE_CUBE_MAP_NEGATIVE_X
2	TEXTURE_CUBE_MAP_POSITIVE_Y
3	TEXTURE_CUBE_MAP_NEGATIVE_Y
4	TEXTURE_CUBE_MAP_POSITIVE_Z
5	TEXTURE_CUBE_MAP_NEGATIVE_Z

Table X.4, Layer numbers for cube map texture faces. The layers are numbered in the same sequence as the cube map face token values.

(modify Section 6.1.3, Enumerated Queries -- Modify/add to list of <pname> values for GetFramebufferAttachmentParameterivEXT if FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE_EXT is TEXTURE)

If <pname> is FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER_EXT and the attached image is a layer of a three-dimensional texture or one- or two-dimensional array texture, then <params> will contain the specified layer number. Otherwise, <params> will contain the value zero.

If <pname> is FRAMEBUFFER_ATTACHMENT_LAYERED_EXT, then <params> will contain TRUE if an entire level of a three-dimesional texture, cube map texture, or one- or two-dimensional array texture is attached to the <attachment>. Otherwise, <params> will contain FALSE.

(Modify the Additions to Chapter 5, section 5.4)

Add the commands FramebufferTextureEXT, FramebufferTextureLayerEXT, and FramebufferTextureFaceEXT to the list of commands that are not compiled into a display list, but executed immediately.

Dependencies on EXT_framebuffer_blit

If EXT_framebuffer_blit is supported, the EXT_framebuffer_object language should be further amended so that <target> values passed to FramebufferTextureEXT and FramebufferTextureLayerEXT can be DRAW_FRAMEBUFFER_EXT or READ_FRAMEBUFFER_EXT, and that those functions set/query state for the draw framebuffer if <target> is FRAMEBUFFER_EXT.

Dependencies on EXT_texture_array

If EXT_texture_array is not supported, the discussion array textures the layered rendering edits to EXT_framebuffer_object should be removed. Layered rendering to cube map and 3D textures would still be supported.

If EXT_texture_array is supported, the edits to EXT_framebuffer_object supersede those made in EXT_texture_array, except for language pertaining to mipmap generation of array textures.

There are no functional incompatibilities between the FBO support in these two specifications. The only differences are that this extension supports layered rendering and also rewrites certain sections of the core FBO specification more aggressively.

Dependencies on ARB_texture_rectangle

    If ARB_texture_rectangle is not supported, all references to rectangle
    textures in the EXT_framebuffer_object spec language should be removed.

Dependencies on EXT_texture_buffer_object

    If EXT_buffer_object is not supported, the reference to an
    INVALID_OPERATION error if a buffer texture is passed to
    FramebufferTextureEXT should be removed.

GLX protocol

    TBD

Errors

    The error INVALID_VALUE is generated by ProgramParameteriEXT if <pname> is
    GEOMETRY_INPUT_TYPE_EXT and <value> is not one of POINTS, LINES,
    LINES_ADJACENCY_EXT, TRIANGLES or TRIANGLES_ADJACENCY_EXT.

    The error INVALID_VALUE is generated by ProgramParameteriEXT if <pname> is
    GEOMETRY_OUTPUT_TYPE_EXT and <value> is not one of POINTS, LINE_STRIP or
    TRIANGLE_STRIP.

    The error INVALID_VALUE is generated by ProgramParameteriEXT if <pname> is
    GEOMETRY_VERTICES_OUT_EXT and <value> is negative.

    The error INVALID_VALUE is generated by ProgramParameteriEXT if <pname> is
    GEOMETRY_VERTICES_OUT_EXT and <value> exceeds
    MAX_GEOMETRY_OUTPUT_VERTICES_EXT.

    The error INVALID_VALUE is generated by ProgramParameteriEXT if <pname> is
    set to GEOMETRY_VERTICES_OUT_EXT and the product of <value> and the sum of
    all components of all active varying variables exceeds
    MAX_GEOMETRY_TOTAL_OUTPUT_COMPONENTS_EXT.

    The error INVALID_OPERATION is generated if Begin, or any command that
    implicitly calls Begin, is called when a geometry shader is active and:

      * the input primitive type of the current geometry shader is
        POINTS and <mode> is not POINTS,

      * the input primitive type of the current geometry shader is
        LINES and <mode> is not LINES, LINE_STRIP, or LINE_LOOP,

      * the input primitive type of the current geometry shader is
        TRIANGLES and <mode> is not TRIANGLES, TRIANGLE_STRIP or
        TRIANGLE_FAN,

      * the input primitive type of the current geometry shader is
        LINES_ADJACENCY_EXT and <mode> is not LINES_ADJACENCY_EXT or
        LINE_STRIP_ADJACENCY_EXT, or

      * the input primitive type of the current geometry shader is
        TRIANGLES_ADJACENCY_EXT and <mode> is not
        TRIANGLES_ADJACENCY_EXT or TRIANGLE_STRIP_ADJACENCY_EXT.

Modifications to the OpenGL Shading Language Specification version 1.10.59

Including the following line in a shader can be used to control the language features described in this extension:

```
  #extension GL_EXT_geometry_shader4 : <behavior>
```

where <behavior> is as specified in section 3.3.

A new preprocessor #define is added to the OpenGL Shading Language:

```
  #define GL_EXT_geometry_shader4 1
```

Change the introduction to Chapter 2 "Overview of OpenGL Shading" as follows:

The OpenGL Shading Language is actually three closely related languages. These languages are used to create shaders for the programmable processors contained in the OpenGL processing pipeline. The precise definition of these programmable units is left to separate specifications. In this document, we define them only well enough to provide a context for defining these languages. Unless otherwise noted in this paper, a language feature applies to all languages, and common usage will refer to these languages as a single language. The specific languages will be referred to by the name of the processor they target: vertex, geometry or fragment.

Change the last sentence of the first paragraph of section 3.2 "Source Strings" to:

Multiple shaders of the same language (vertex, geometry or fragment) can be linked together to form a single program.

Change the first paragraph of section 4.1.3, "Integers" as follows:

... integers are limited to 16 bits of precision, plus a sign representation in the vertex, geometry and fragment languages..

Change the first paragraph of section 4.1.9, "Arrays", as follows:

Variables of the same type can be aggregated into one- and two-dimensional arrays by declaring a name followed by brackets ([ ] for one-dimensional arrays and [][] for two-dimensional arrays) enclosing an optional size. When an array size is specified in a declaration, it must be an integral constant expression (see Section 4.3.3 "Integral Constant Expressions") greater than zero. If an array is indexed with an expression that is not an integral constant expression or passed as an argument to a function, then its size must be declared before any such use. It is legal to declare an array without a size and then later re-declare the same name as an array of the same type and specify a size. It is illegal to declare an array with a size, and then later (in the same shader) index the same array with an integral constant expression greater than or equal to the declared size. It is also illegal to index an array with a negative constant expression. Arrays declared as formal parameters in a function declaration must specify a size. Undefined behavior results from indexing an array with a non-constant expression that's greater than or equal to the array's size or less than 0. All basic types and structures can be formed into arrays.

Two-dimensional arrays can only be declared as "varying in" variables in a geometry shader. See section 4.3.6 for details. All other declarations of two-dimensional arrays are illegal.

Change the fourth paragraph of section 4.2 "Scoping", as follows:

Shared globals are global variables declared with the same name in independently compiled units (shaders) of the same language (vertex, geometry or fragment) that are linked together .

Change section 4.3 "Type Qualifiers"

Change the "varying", "in" and "out" qualifiers as follows:

varying - linkage between a vertex shader and geometry shader, or between a geometry shader and a fragment shader, or between a vertex shader and a fragment shader.

in - for function parameters passed into a function or for input varying variables (geometry only)

out - for function parameters passed back out of a function, but not initialized for use when passed in. Also for output varying variables (geometry only).

Change section 4.3.6 "Varying" as follows:

Varying variables provide the interface between the vertex shader and geometry shader and also between the geometry shader and fragment shader and the fixed functionality between them. If no geometry shader is present, varying variables also provide the interface between the vertex shader and fragment shader.

The vertex, or geometry shader will compute values per vertex (such as color, texture coordinates, etc) and write them to output variables declared with the "varying" qualifier (vertex or geometry) or "varying out" qualifiers (geometry only). A vertex or geometry shader may also read these output varying variables, getting back the same values it has written. Reading an output varying variable in a vertex or geometry shader returns undefined results if it is read before being written.

A geometry shader may also read from an input varying variable declared with the "varying in" qualifiers. The value read will be the same value as written by the vertex shader for that varying variable. Since a geometry shader operates on primitives, each input varying variable needs to be declared as an array. Each element of such an array corresponds to a vertex of the primitive being processed. If the varying variable is declared as a scalar or matrix in the vertex shader, it will be a one-dimensional array in the geometry shader. Each array can optionally have a size declared. If a size is not specified, it inferred by the linker and depends on the value of the input primitive type. See table 4.3.xxx to determine the exact size. The read-only built-in constant gl_VerticesIn will be set to this value by the linker. If a size is specified, it has to be the size as given by table 4.3.xxx, otherwise a link error will occur. The built-in constant gl_VerticesIn, if so desired, can be used to size the array correctly for each input primitive type. Varying variables can also be declared as arrays in the vertex shader. This means that those, on input to the geometry shader, must be declared as two- dimensional arrays. The first index to the two-dimensional array holds the vertex number. Declaring a size for the first range of the array is optional, just as it is for one-dimensional arrays. The second index holds the per-vertex array data. Declaring a size for the second range of the array is not optional, and has to match the declaration in the vertex shader.

Input primitive type	Value of built-in gl_VerticesIn
POINTS	1
LINES	2
LINES_ADJACENCY_EXT	4
TRIANGLES	3
TRIANGLES_ADJACENCY_EXT	6

Table 4.3.xxxx The value of the built-in variable gl_VerticesIn is determined at link time, based on the input primitive type.

It is illegal to index these varying arrays, or in the case of two-dimensional arrays, the first range of the array, with a negative integral constant expression or an integral constant expression greater than or equal to gl_VerticesIn. A link error will occur in these cases.

Varying variables that are part of the interface to the fragment shader are set per vertex and interpolated in a perspective correct manner, unless flat shaded, over the primitive being rendered. If single-sampling, the interpolated value is for the fragment center. If multi-sampling, the interpolated value can be anywhere within the pixel, including the fragment center or one of the fragment samples.

A fragment shader may read from varying variables and the value read will be the interpolated value, as a function of the fragment's position within the primitive, unless the varying variable is flat shaded. A fragment shader cannot write to a varying variable.

If a geometry shader is present, the type of the varying variables with the same name declared in the vertex shader and the input varying variables in the geometry shader must match, otherwise the link command will fail. Likewise, the type of the output varying variables with the same name declared in the geometry shader and the varying variables in the fragment shader must match.

If a geometry shader is not present, the type of the varying variables with the same name declared in both the vertex and fragment shaders must match, otherwise the link command will fail.

Only those varying variables used (i.e. read) in the geometry or fragment shader must be written to by the vertex or geometry shader; declaring superfluous varying variables in the vertex shader or declaring superfluous output varying variables in the geometry shader is permissible.

Varying variables are declared as in the following example:

```
  varying in float foo[];    // geometry shader input. Size of the
                             // array set as a result of link, based
                             // on the input primitive type.

  varying in float foo[gl_VerticesIn]; // geometry shader input

  varying in float foo[3];   // geometry shader input. Only legal for
                             // the TRIANGLES input primitive type

  varying in float foo[][5]; // Size of the first range set as a
                             // result of link. Each vertex holds an
                             // array of 5 floats.

  varying out vec4 bar;      // geometry output
  varying vec3 normal;       // vertex shader output or fragment
                             // shader input
```

The varying qualifier can be used only with the data types float, vec2, vec3, vec4, mat2, mat3 and mat4 or arrays of these. Structures cannot be varying. Additionally, the "varying in" and "varying out" qualifiers can only be used in a geometry shader.

If no vertex shader is active, the fixed functionality pipeline of OpenGL will compute values for the built-in varying variables that will be consumed by the fragment shader. Similarly, if no fragment shader is active, the vertex shader or geometry shader is responsible for computing and writing to the built-in varying variables that are needed for OpenGL's fixed functionality fragment pipeline.

Varying variables are required to have global scope, and must be declared outside of function bodies, before their first use.

Change section 7.1 "Vertex Shader Special Variables"

Rename this section to "Vertex and Geometry Shader Special Variables"

Anywhere in this section where it reads "vertex language" replace it with "vertex and geometry language".

Anywhere in this section where it reads "vertex shader" replace it with "vertex shader or geometry shader".

Change the second paragraph to:

The variable gl_Position is available only in the vertex and geometry language and is intended for writing the homogeneous vertex position. It can be written at any time during shader execution. It may also be read back by the shader after being written. This value will be used by primitive assembly, clipping, culling, and other fixed functionality operations that operate on primitives after vertex or geometry processing has occurred. Compilers may generate a diagnostic message if they detect gl_Position is read before being written, but not all such cases are detectable. Writing to gl_Position is optional. If gl_Position is not written but subsequent stages of the OpenGL pipeline consume gl_Position, then results are undefined.

Change the last sentence of this section into the following:

The read-only built-in gl_PrimitiveIDIn is available only in the geometry language and is filled with the number of primitives processed by the geometry shader since the last time Begin was called (directly or indirectly via vertex array functions). See section 2.16.4 for more information.

This variable is intrinsically declared as:

```
    int gl_PrimitiveIDIn; // read only
```

The built-in output variable gl_PrimitiveID is available only in the geometry language and provides a single integer that serves as a primitive identifier. This written primitive ID is available to fragment shaders. If a fragment shader using primitive IDs is active and a geometry shader is also active, the geometry shader must write to gl_PrimitiveID or the primitive ID in the fragment shader number is undefined.

The built-in output variable gl_Layer is available only in the geometry language, and provides the number of the layer of textures attached to a FBO to direct rendering to. If a shader statically assigns a value to gl_Layer, layered rendering mode is enabled. See section 2.16.4 for a detailed explanation. If a shader statically assigns a value to gl_Layer, and there is an execution path through the shader that does not set gl_Layer, then the value of gl_Layer may be undefined for executions of the shader that take that path.

These variables area intrinsically declared as:

```
    int gl_PrimitiveID;
    int gl_Layer;
```

These variables can be read back by the shader after writing to them, to retrieve what was written. Reading the variable before writing it results in undefined behavior. If it is written more than once, the last value written is consumed by the subsequent operations.

All built-in variables discussed in this section have global scope.

Change section 7.2 "Fragment Shader Special Variables"

Change the first paragraph on p. 44 as follows:

The fragment shader has access to the read-only built-in variable gl_FrontFacing whose value is true if the fragment belongs to a front-facing primitive. One use of this is to emulate two-sided lighting by selecting one of two colors calculated by the vertex shader or geometry shader.

Change the first sentence of section 7.4 "Built-in Constants"

The following built-in constant is provided to geometry shaders.

```
  const int gl_VerticesIn; // Value set at link time
```

The following built-in constants are provided to the vertex, geometry and fragment shaders:

Change section 7.6 "Varing Variables"

Unlike user-defined varying variables, the built-in varying variables don't have a strict one-to-one correspondence between the vertex language, geometry language and the fragment language. Four sets are provided, one set for the vertex language output, one set for the geometry language output, one set for the fragment language input and another set for the geometry language input. Their relationship is described below.

The following built-in varying variables are available to write to in a vertex shader or geometry shader. A particular one should be written to if any functionality in a corresponding geometry shader or fragment shader or fixed pipeline uses it or state derived from it. Otherwise, behavior is undefined.

Vertex language built-in outputs:

```
  varying vec4 gl_FrontColor;
  varying vec4 gl_BackColor;
  varying vec4 gl_FrontSecondaryColor;
  varying vec4 gl_BackSecondaryColor;
  varying vec4 gl_TexCoord[]; // at most will be gl_MaxTextureCoords
  varying float gl_FogFragCoord;
```

Geometry language built-in outputs:

```
  varying out vec4 gl_FrontColor;
  varying out vec4 gl_BackColor;
  varying out vec4 gl_FrontSecondaryColor;
  varying out vec4 gl_BackSecondaryColor;
  varying out vec4 gl_TexCoord[]; // at most gl_MaxTextureCoords
  varying out float gl_FogFragCoord;
```

For gl_FogFragCoord, the value written will be used as the "c" value on page 160 of the OpenGL 1.4 Specification by the fixed functionality pipeline. For example, if the z-coordinate of the fragment in eye space is desired as "c", then that's what the vertex or geometry shader should write into gl_FogFragCoord.

Indices used to subscript gl_TexCoord must either be an integral constant expressions, or this array must be re-declared by the shader with a size. The size can be at most gl_MaxTextureCoords. Using indexes close to 0 may aid the implementation in preserving varying resources.

The following input varying variables are available to read from in a geometry shader.

```
  varying in vec4 gl_FrontColorIn[gl_VerticesIn];
  varying in vec4 gl_BackColorIn[gl_VerticesIn];
  varying in vec4 gl_FrontSecondaryColorIn[gl_VerticesIn];
  varying in vec4 gl_BackSecondaryColorIn[gl_VerticesIn];
  varying in vec4 gl_TexCoordIn[gl_VerticesIn][]; // at most will be
                                                  // gl_MaxTextureCoords
  varying in float gl_FogFragCoordIn[gl_VerticesIn];
  varying in vec4 gl_PositionIn[gl_VerticesIn];
  varying in float gl_PointSizeIn[gl_VerticesIn];
  varying in vec4 gl_ClipVertexIn[gl_VerticesIn];
```

All built-in variables are one-dimensional arrays, except for gl_TexCoordIn, which is a two-dimensional array. Each element of a one-dimensional array, or the first index of a two-dimensional array, corresponds to a vertex of the primitive being processed and receives their value from the equivalent vertex output varying variables. See also section 4.3.6.

The following varying variables are available to read from in a fragment shader. The gl_Color and gl_SecondaryColor names are the same names as attributes passed to the vertex shader. However, there is no name conflict, because attributes are visible only in vertex shaders and the following are only visible in a fragment shader.

```
  varying vec4 gl_Color;
  varying vec4 gl_SecondaryColor;
  varying vec4 gl_TexCoord[]; // at most will be gl_MaxTextureCoords
  varying float gl_FogFragCoord;
```

The values in gl_Color and gl_SecondaryColor will be derived automatically by the system from gl_FrontColor, gl_BackColor, gl_FrontSecondaryColor, and gl_BackSecondaryColor. This selection process is described in section 2.14.1 of the OpenGL 2.0 Specification. If fixed functionality is used for vertex processing, then gl_FogFragCoord will either be the z-coordinate of the fragment in eye space, or the interpolation of the fog coordinate, as described in section 3.10 of the OpenGL 1.4 Specification. The gl_TexCoord[] values are the interpolated gl_TexCoord[] values from a vertex or geometry shader or the texture coordinates of any fixed pipeline based vertex functionality.

Indices to the fragment shader gl_TexCoord array are as described above in the vertex and geometry shader text.

Change section 8.7 "Texture Lookup Functions"

Change the first paragraph to:

Texture lookup functions are available to vertex, geometry and fragment shaders. However, level of detail is not computed by fixed functionality for vertex or geometry shaders, so there are some differences in operation between texture lookups. The functions.

Change the third and fourth paragraphs to:

In all functions below, the bias parameter is optional for fragment shaders. The bias parameter is not accepted in a vertex or geometry shader. For a fragment shader, if bias is present, it is added to the calculated level of detail prior to performing the texture access operation. If the bias parameter is not provided, then the implementation automatically selects level of detail: For a texture that is not mip-mapped, the texture is used directly. If it is mip- mapped and running in a fragment shader, the LOD computed by the implementation is used to do the texture lookup. If it is mip- mapped and running on the vertex or geometry shader, then the base LOD of the texture is used.

The built-ins suffixed with "Lod" are allowed only in a vertex or geometry shader. For the "Lod" functions, lod is directly used as the level of detail.

Change section 8.9 Noise Functions

Change the first paragraph to:

Noise functions are available to the vertex, geometry and fragment shaders. They are...

Add a section 8.10 Geometry Shader Functions

This section contains functions that are geometry language specific.

Syntax:

```
    void EmitVertex();   // Geometry only
    void EndPrimitive(); // Geometry only
```

Description:

The function EmitVertex() specifies that a vertex is completed. A vertex is added to the current output primitive using the current values of the varying output variables and the current values of the special built-in output variables gl_PointSize, gl_ClipVertex, gl_Layer, gl_Position and gl_PrimitiveID. The values of any unwritten output variables are undefined. The values of all varying output variables and the special built-in output variables are undefined after a call to EmitVertex(). If a geometry shader, in one invocation, emits more vertices than the value GEOMETRY_VERTICES_OUT_EXT, these emits may have no effect.

The function EndPrimitive() specifies that the current output primitive is completed and a new output primitive (of the same type) should be started. This function does not emit a vertex. The effect of EndPrimitive() is roughly equivalent to calling End followed by a new Begin, where the primitive mode is taken from the program object parameter GEOMETRY_OUTPUT_TYPE_EXT. If the output primitive type is POINTS, calling EndPrimitive() is optional.

A geometry shader starts with an output primitive containing no vertices. When a geometry shader terminates, the current output primitive is automatically completed. It is not necessary to call EndPrimitive() if the geometry shader writes only a single primitive.

Add/Change section 9 (Shading language grammar):

```
  init_declarator_list:
    single_declaration
    init_declarator_list COMMA IDENTIFIER
    init_declarator_list COMMA IDENTIFIER array_declarator_suffix
    init_declarator_list COMMA IDENTIFIER EQUAL initializer

  single_declaration:
    fully_specified_type
    fully_specified_type IDENTIFIER
    fully_specified_type IDENTIFIER array_declarator_suffix
    fully_specified_type IDENTIFIER EQUAL initializer

NVIDIA Implementation Details

Because of a hardware limitation, some GeForce 8 series chips use the odd vertex of an incomplete TRIANGLE_STRIP_ADJACENCY_EXT primitive as a replacement adjacency vertex rather than ignoring it.

Issues

1. *How do geometry shaders fit into the existing GL pipeline?*

   RESOLVED: The following diagram illustrates how geometry shaders fit into the "vertex processing" portion of the GL (Chapter 2 of the OpenGL 2.0 Specification).

   First, vertex attributes are specified via immediate-mode commands or through vertex arrays. They can be conventional attributes (e.g., glVertex, glColor, glTexCoord) or generic (numbered) attributes.

   Vertices are then transformed, either using a vertex shader or fixed-function vertex processing. Fixed-function vertex processing includes position transformation (modelview and projection matrices), lighting, texture coordinate generation, and other calculations. The results of either method are a "transformed vertex", which has a position (in clip coordinates), front and back colors, texture coordinates, generic attributes (vertex shader only), and so on. Note that on many current GL implementations, vertex processing is performed by executing a "fixed function vertex shader" generated by the driver.

After vertex transformation, vertices are assembled into primitives, according to the topology (e.g., TRIANGLES, QUAD_STRIP) provided by the call to glBegin(). Primitives are points, lines, triangles, quads, or polygons. Many GL implementations do not directly support quads or polygons, but instead decompose them into triangles as permitted by the spec.

After initial primitive assembly, a geometry shader is executed on each individual point, line, or triangle primitive, if one is active. It can read the attributes of each transformed vertex, perform arbitrary computations, and emit new transformed vertices. These emitted vertices are themselves assembled into primitives according to the output primitive type of the geometry shader.

Then, the colors of the vertices of each primitive are clamped to [0,1] (if color clamping is enabled), and flat shading may be performed by taking the color from the provoking vertex of the primitive.

Each primitive is clipped to the view volume, and to any enabled user-defined clip planes. Color, texture coordinate, and other attribute values are computed for each new vertex introduced by clipping.

After clipping, the position of each vertex (in clip coordinates) is converted to normalized device coordinates in the perspective division (divide by w) step, and to window coordinates in the viewport transformation step.

At the same time, color values may be converted to normalized fixed-point values according to the "Final Color Processing" portion of the specification.

After the vertices of the primitive are transformed to window coordinate, the GL determines if the primitive is front- or back-facing. That information is used for two-sided color selection, where a single set of colors is selected from either the front or back colors associated with each transformed vertex.

When all this is done, the final transformed position, colors (primary and secondary), and other attributes are used for rasterization (Chapter 3 in the OpenGL 2.0 Specification).

When the raster position is specified (via glRasterPos), it goes through the entire vertex processing pipeline as though it were a point. However, geometry shaders are never run on the raster position.

```

```

2. *Why is this called GL_EXT_geometry_shader4? There aren't any previous versions of this extension, let alone three?*

   RESOLVED: To match its sibling, EXT_gpu_shader4 and the assembly version NV_gpu_program4. This is the fourth generation of shading functionality, hence the "4" in the name.

3. *Should the GL produce errors at Begin time if an application specifies a primitive mode that is "incompatible" with the geometry shader? For example, if the geometry shader operates on triangles and the application sends a POINTS primitive?*

   RESOLVED: Yes. Mismatches of app-specified primitive types and geometry shader input primitive types appear to be errors and would produce weird and wonderful effects.

4. *Can the input primitive type of a geometry shader be determined at run time?*

   RESOLVED: No. Each geometry shader has a single input primitive type, and vertices are presented to the shader in a specific order based on that type.

5. *Can the input primitive type of a geometry shader be changed?*

   DISCUSSION: The input primitive type is a property of the program object. A change of the input primitive type means the program object will need to be re-linked. It would be nice if the input primitive type was known at compile time, so that the compiler can do error checking of the type and the number of vertices being accessed by the shader. Since we allow multiple compilation units to form one geometry shader, it is not clear how to achieve that. Therefore, the input primitive type is a property of the program object, and not of a shader object.

   RESOLVED: Yes, but each change means the program object will have to be re-linked.

6. *Can the output primitive type of a geometry shader be determined at run time?*

   RESOLVED: Not in this extension.

7. *Can the output primitive type of a program object be changed?*

   RESOLVED: Yes, but the program object will have to be re-linked in order for the change to have effect on program execution.

8. *Must the output primitive type of a geometry shader match the input primitive type in any way?*

   RESOLVED: No, you can have a geometry shader generate points out of triangles or triangles out of points. Some combinations are analogous to existing OpenGL operations: reading triangles and writing points or line strips can be used to emulate a subset of PolygonMode functionality. Reading points and writing triangle strips can be used to emulate point sprites.

9. *Are primitives emitted by a geometry shader processed like any other OpenGL primitive?*

   RESOLVED: Yes. Antialiasing, stippling, polygon offset, polygon mode, culling, two-sided lighting and color selection, point sprite operations, and fragment processing all work as expected.

   One limitation is that the only output primitive types supported are points, line strips, and triangle strips, none of which meaningfully support edge flags that are sometimes used in conjunction with the POINT and LINE polygon modes. Edge flags are always ignored for line-mode triangle strips.

10. *Should geometry shaders support additional input primitive types?*

    RESOLVED: Possibly in a future extension. It should be straightforward to build a future extension to support geometry shaders that operate on quads. Other primitive types might be more demanding on hardware. Quads with adjacency would require 12 vertices per shader execution. General polygons may require even more, since there is no fixed bound on the number of vertices in a polygon.

11. *Should geometry shaders support additional output primitive types?*

    RESOLVED: Possibly in a future extension. Additional output types (e.g., independent lines, line loops, triangle fans, polygons) may be useful in the future; triangle fans/polygons seem particularly useful.

12. *How are adjacency primitives processed by the GL?*

    RESOLVED: The primitive type of an adjacent primitive is set as a Begin mode parameter. Any vertex of an adjacency primitive will be treated as a regular vertex, and processed by a vertex shader as well as the geometry shader. The geometry shader cannot output adjacency primitives, thus processing stops with the geometry shader. If a geometry shader is not active, the GL ignores the "adjacent" vertices in the adjacency primitive.

13. *Should we provide additional adjacency primitive types that can be used inside a Begin/End?*

    RESOLVED: Not in this extension. It may be desirable to add new primitive types (e.g., TRIANGLE_FAN_ADJACENCY) in a future extension.

14. *How do geometry shaders interact with RasterPos?*

    RESOLVED: Geometry shaders are ignored when specifying the raster position.

15. *How do geometry shaders interact with pixel primitives (DrawPixels, Bitmap)?*

    RESOLVED: They do not.

16. *Is there a limit on the number of vertices that can be emitted by* a geometry shader?

    RESOLVED: Unfortunately, yes. Besides practical hardware limits, there may also be practical performance advantages when applications guarantee a tight upper bound on the number of vertices a geometry shader will emit. GPUs frequently excecute programs in parallel, and there are substantial implementation challenges to parallel execution of geometry threads that can write an unbounded number of results, particular given that all the primitives generated by the first geometry shader invocation must be consumed before any of the primitives generated by the second program invocation. Limiting the amount of data a geometry shader can write substantially eases the implementation burden.

    A program object, holding a geometry shader, must declare a maximum number of vertices that can be emitted. There is an implementation-dependent limit on the total number of vertices a program object can emit (256 minimum) and the product of the number of vertices emitted and the number of components of all active varying variables (1024 minimum).

    It would be ideal if the limit could be inferred from the instructions in the shader itself, and that would be possible for many shaders, particularly ones with straight-line flow control. For shaders with more complicated flow control (subroutines, data- dependent looping, and so on), it would be impossible to make such an inference and a "safe" limit would have to be used with adverse and possibly unexpected performance consequences.

    The limit on the number of EmitVertex() calls that can be issued can not always be enforced at compile time, or even at Begin time. We specify that if a shader tries to emit more vertices than allowed, emits that exceed the limit may or may not have any effect.

17. *Should it be possible to change the limit GEOMETRY_VERTICES_OUT_EXT, the number of vertices emitted by a geometry shader, after the program object, containing the shader, is linked?*

    RESOLVED: NO. See also issue 31. Changing this limit might require a re-compile and/or re-link of the shaders and program object on certain implementations. Pretending that this limit can be changed without re-linking does not reflect reality.

18. *How do user clipping and geometry shaders interact?*

    RESOLVED: Just like vertex shaders and user clipping interact. The geometry shader needs to provide the (eye) position gl_ClipVertex. Primitives are clipped after geometry shader execution, not before.

19. *How do edge flags interact with adjacency primitives?*

    RESOLVED: If geometry programs are disabled, adjacency primitives are still supported. For TRIANGLES_ADJACENCY_EXT, edge flags will apply as they do for TRIANGLES. Such primitives are rendered as independent triangles as though the adjacency vertices were not provided. Edge flags for the "real" vertices are supported. For all other adjacency primitive types, edge flags are irrelevant.

20. *Now that a third shader object type is added, what combinations of GLSL, assembly (ARB or NV) low level and fixed-function do we want to support?*

    DISCUSSION: With the addition of the geometry shader, the number of combinations the GL pipeline could support doubled (there is no fixed-function geometry shading). Possible combinations now are:

vertex	geometry	fragment
ff/ASM/GLSL	none/ASM/GLSL	ff/ASM/GLSL

    for a total of 3 x 3 x 3 is 27 combinations. Before the geometry shader was added, the number of combinations was 9, and those we need to support. We have a choice on the other 18.

    RESOLUTION: It makes sense to draw a line at raster in the GL pipeline. The 'north' side of this line covers vertex and geometry shaders, the 'south' side fragment shaders. We now add a simple rule that states that if a program object contains anything north of this line, the north side will be 100% GLSL. This means that:

    a) GLSL program objects with a vertex shader can only use a geometry shader and not an assembly geometry program. If an assembly geometry program is enabled, it is bypassed. This also avoids a tricky case -- a GLSL program object with a vertex and a fragment program linked together. Injecting an assembly geometry shader in the middle at run time won't work well.

    b) GLSL program objects with a geometry shader must have a vertex shader (cannot be ARB/NV or fixed-function vertex shading).

    The 'south' side in this program object still can be any of ff/ARB/NV/GLSL.

21. *How do geometry shaders interact with color clamping?*

    RESOLVED: Geometry shader execution occurs prior to color clamping in the pipeline. This means the colors written by vertex shaders are not clamped to [0,1] before they are read by geometry shaders. If color clamping is enabled, any vertex colors written by the geometry shader will have their components clamped to [0,1].

22. *What is a primitive ID and a vertex ID? I am confused.*

    DISCUSSION: A vertex shader can read a built-in attribute that holds the ID of the current vertex it is processing. See the EXT_gpu_shader4 spec for more information on vertex ID. If the geometry shader needs access to a vertex ID as well, it can be passed as a user-defined varying variable. A geometry shader can read a built-in varying variable that holds the ID of the current primitive it is processing. It also has the ability to write to a built-in output primitive ID variable, to communicate the primitive ID to a fragment shader. A fragment shader can read a built-in attribute that holds the ID of the current primitive it is processing. A primitive ID will be generated even if no geometry shader is active.

23. After a call to EmitVertex(), should the values of the output varying variables be retained or be undefined?

DISCUSSION: There is not a clear answer to this question .The underlying HW mechanism is as follows. An array of output registers is set aside to store vertices that make up primitives. After each EmitVertex() a pointer into that array is incremented. The shader no longer has access to the previous set of values. This argues that the values of output varying variables should be undefined after an EmitVertex() call. The shader is responsible for writing values to all varying variables it wants to emit, for each emit. The counter argument to this is that this is not a nice model for GLSL to program in. The compiler can store varying outputs in a temp register and preserve their values across EmitVertex() calls, at the cost of increased register pressure.

RESOLUTION: For now, without being a clear winner, we've decided to go with the undefined option. The shader is responsible for writng values to all varying variabvles it wants to emit, for each emit.

24. How to distinguish between input and output "varying" variables?

DISCUSSION: Geometry shader outputs are varying variables consistent with the existing definition of varying (used to communicate to the fragment processing stage). Geometry inputs are received from a vertex shader writing to its varying variable outputs. The inputs could be called "varying", to match with the vertex shader, or could be called "attributes" to match the vertex shader inputs (which are called attributes).

RESOLUTION: We'll call input variables "varying", and not "attributes". To distinguish between input and output, they will be further qualified with the words "in" and "out" resulting in, for example:

```
varying in float foo;
varying out vec4 bar[];
```

25. What is the syntax for declaring varying input variables?

DISCUSSION: We need a way to distinguish between the vertices of the input primitive. Suggestions:

1. Declare each input varying variable as an unsized array. Its size is inferred by the linker based on the output primitive type.

2. Declare each input varying variable as a sized array. If the size does not match the output primitive type, a link error occurs.

3. Have an array of structures, where the structure contains the attributes for each vertex.

RESOLUTION: Option 1 seems simple and solves the problem, but it is not a clear winner over the other two. To aid the shader writer in figuring out the size of each array, a new built-in constant, gl_VerticesIn, is defined that holds the number of vertices for the current input primitive type.

26. *Does gl_PointSize, gl_Layer, gl_ClipVertex count agains the MAX_GEOMETRY_VARYING_COMPONENTS limit?*

    RESOLUTION: Core OpenGL 2.0 makes a distinction between varying variables, output from a vertex shader and interpolated over a primitive, and 'special built-in variables' that are outputs, but not interpolated across a primitive. Only varying variables do count against the MAX_VERTEX_VARYING_COMPONENTS limit. gl_PointSize, gl_Layer, gl_ClipVertex and gl_Position are 'special built-in' variables, and therefore should not count against the limit. If HW does need to take components away to support those, that is ok. The actual spec language does mention possible implementation dependencies.

27. *Should writing to gl_Position be optional?*

    DISCUSSION: Before this extensions, the OpenGL Shading Language required that gl_Position be written to in a vertex shader. With the addition of geometry shaders, it is not necessary anymore for a vertex shader to output gl_Position. The geometry shader can do so. With the addition of transform-feedback (see the transform feedback specification) it is not necessary useful for the geometry shader to write out gl_Position either.

    RESOLUTION: Yes, this should be optional.

28. *Should geometry shaders be able to select a layer of a 3D texture, cube map texture, or array texture at run time? If so, how?*

    RESOLVED: See also issue 32. This extension provides a per-vertex output called "gl_Layer", which is an integer specifying the layer to render to. In order to get defined results, the value of gl_Layer needs to be constant for each primitive (point, line or triangle) being emitted by a geometry shader. This layer value is used for all fragments generated by that primitive.

    The EXT_framebuffer_object (FBO) extension is used for rendering to textures, but for cube maps and 3D textures, it only provides the ability to attach a single face or layer of such textures.

    This extension generalizes FBO by creates new entry points to bind an entire texture level (FramebufferTextureEXT) or a single layer of a texture level (FramebufferTextureLayerEXT) or a single face of a level of a cube map texture (FramebufferTextureFaceEXT) to an attachment point. The existing FBO binding functions, FramebufferTexture[123]DEXT are retained, and are defined in terms of the more general new functions.

    The new functions do not have a dimension in the function name or a <textarget> parameter, which can be inferred from the provided texture.

    When an entire texel level of a cube map, 3D, or array texture is attached, that attachment is considered layered. The framebuffer is considered layered if any attachment is layered. When the framebuffer is layered, there are three additional completeness requirements:

  * all attachments must be layered
  * all color attachments must be from textures of identical type
  * all attachments must have the same number of layers

We expect subsequent versions of the FBO spec to relax the requirement that all attachments must have the same width and height, and plan to relax the similar requirement for layer count at that time.

When rendering to a layered framebuffer, layer zero is used unless a geometry shader that writes (statically assings, to be precise) to gl_Layer. When rendering to a non-layered framebuffer, the value of gl_Layer is ignored and the set of single-image attachments are used. When reading from a layered framebuffer (e.g., ReadPixels), layer zero is always used. When clearing a layered framebuffer, all layers are cleared to the corresponding clear values.

Several other approaches were considered, including leveraging existing FBO attachment functions and requiring the use of FramebufferTexture3D with a <zoffset> of zero to make a framebuffer attachment "layerable" (attaching layer zero means that the attachment could be used for either layered- or non- layered rendering). Whether rendering was layered or not could either be inferred from the active geometry shader, or set as a new property of the framebuffer object. There is presently no FramebufferParameter API to set a property of a framebuffer, so it would have been necessary to create new set/query APIs if this approach were chosen.

29. *How should per-vertex point size work with geometry shaders?*

RESOLVED: The value of the existing VERTEX_PROGRAM_POINT_SIZE enable, to control the point size behavior of a vertex shader, does not affect geometry shaders. Specifically, If a geometry shader is active, the point size is taken from the point size output gl_PointSize of the vertex shader, regardless of the value of VERTEX_PROGRAM_POINT_SIZE.

30. *Geometry shaders don't provide a QUADS or generic POLYGON input primitive type. In this extension, what happens if an application provides QUADS, QUAD_STRIP, or POLYGON primitives?*

RESOLVED: Not all vendors supporting this extension were able to accept quads and polygon primitives as input, so such functionality was not provided in this extension. This extension requires that primitives provided to the GL must match the input primitive type of the active geometry shader (if any). QUADS, QUAD_STRIP, and POLYGON primitives are considered not to match any input primitive type, so an INVALID_OPERATION error will result.

The NV_geometry_shader4 extension (built on top of this one) allows applications to provide quads or general polygon primitives to a geometry shader with an input primitive type of TRIANGLES. Such primitives are decomposed into triangles, and a geometry shader is run on each triangle independently.

31. *Geometry shaders provide a limit on the number of vertices that can be emitted. Can this limit be changed at dynamically?*

    RESOLVED: See also issue 17. Not in this extension. This functionality was not provided because it would be an expensive operation on some implementations of this extension. The NV_geometry_shader4 extension (layered on top of this one) does allow applications to change this limit dynamically.

    An application can change the vertex output limit at any time. To allow for the possibility of dynamic changes (as in NV_geometry_shader4) but not require it, a limit change is not guaranteed to take effect unless the program object is re-linked. However, there is no guarantee that such limit changes will not take effect immediately.

32. *See also issue 28. Each vertex emitted by a geometry shader can specify a layer to render to using the output variable "gl_Layer". For LINE_STRIP and TRIANGLE_STRIP output primitive types, which vertex's layer is used?*

    RESOLVED: The vertex from which the layer is extracted is unfortunately undefined. In practice, some implementations of this extension will extract the layer number from the first vertex of the output primitive; others will extract it from the last (provoking) vertex. A future geometry shader extension may choose to define this behavior one way or the other.

    To get portable results, the layer number should be the same for all vertices in any single primitive emitted by the geometry shader. The EndPrimitive() built-in function available in a geometry shader starts a new primitive, and the layer number emitted can be safely changed after EndPrimitive() is called.

33. The grammar allows "varying", "varying out", and "varying in" as type-qualifiers for geometry shaders. What does "varying" without "in" or "out" mean for a geometry shader?

    RESOLVED: The "varying" type qualifier in a geometry shader not followed by "in" or "out" means the same as "varying out".

    This is consistent with the specification saying: "In order to seamlessly be able to insert or remove a geometry shader from a program object, the rules, names and types of the output built-in varying variables and user-defined varying variables are the same as for the vertex shader."

Revision History

```
    Rev.    Date    Author    Changes
    ----  --------  --------  -----------------------------------------
     17   05/22/07  mjk       Clarify that "varying" means the same as
                              "varying out" in a geometry shader.

     16   01/10/07  pbrown    Specify that the total component limit is
                              enforced at LinkProgram time.
     15   12/15/06  pbrown    Documented that the '#extension' token
                              for this extension should begin with "GL_",
                              as apparently called for per convention.

Dependencies

    ARB_vertex_program or ARB_fragment_program is required.

    This specification is written against the spec language from the
    ARB_vertex_program extension.

Overview

    This extension provides a new set of procedures to load multiple
    consecutive program environment parameters more efficiently, via a single
    GL call instead of multiple calls. This will reduce the amount of CPU
    overhead involved in loading parameters.

    With the existing ARB_vertex_program and ARB_fragment_program APIs,
    program parameters must be loaded one at a time, via separate calls.
    While the NV_vertex_program extension provides a set of similar functions
    that can be used to load program environment parameters (which are
    equivalent to "program parameters" in NV_vertex_program), no such function
    exists for program local parameters.

New Procedures and Functions

```
    void ProgramEnvParameters4fvEXT(enum target, uint index, sizei count,
                                   const float *params);

    void ProgramLocalParameters4fvEXT(enum target, uint index, sizei count,
                                     const float *params);
```

New Tokens

    None.

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

(modify ARB_vertex_program and ARB_fragment_program, add paragraph after introduction of ProgramEnvParameter* calls)

The command

```
      void ProgramEnvParameters4fvEXT(enum target, uint index, sizei count,
                                      const float *params);
```

updates the values of the program environment parameters numbered <index> through <index> + <count> - 1 for the given program target <target>. <params> points to an array of 4*<count> values, where the first four are used to update the program environment parameter numbered <index> and the last four update the program environment parameter numbered <index> + <count> - 1. The error INVALID_VALUE is generated if <count> is less than zero or if the sum of <index> and <count> is greater than the number of program environment parameters supported by <target>.

(modify ARB_vertex_program and ARB_fragment_program, add paragraph after introduction of ProgramLocalParameter* calls)

The command

```
      void ProgramLocalParameters4fvEXT(enum target, uint index, sizei count,
                                        const float *params);
```

updates the values of the program local parameters numbered <index> through <index> + <count> - 1 belonging to the program object currently bound to <target>. <params> points to an array of 4*<count> values, where the first four are used to update the program local parameter numbered <index> and the last four update the program local parameter numbered <index> + <count> - 1. The error INVALID_VALUE is generated if <count> is less than zero or if the sum of <index> and <count> is greater than the number of program local parameters supported by <target>.

GLX Protocol

Four new GL commands are added. The following commands are sent to the server as part of a glXRender request:

```
    ProgramEnvParameters4fvEXT
        2           16+16*n         rendering command length
        2           4281            rendering command opcode
        4           ENUM            target
        4           CARD32          index
        4           CARD32          n
        16*n        FLOAT32         params

    ProgramLocalParameters4fvEXT
        2           16+16*n         rendering command length
        2           4282            rendering command opcode
        4           ENUM            target
        4           CARD32          index
        4           CARD32          n
        16*n        FLOAT32         params
```

Errors

INVALID_VALUE is generated by ProgramEnvParameters4fvEXT or ProgramLocalParameters4fvEXT if <count> is less than zero.

INVALID_VALUE is generated by ProgramEnvParameters4fvEXT if <index> plus <count> is greater than the number of program environment parameters supported by <target>.

INVALID_VALUE is generated by ProgramLocalParameters4fvEXT if <index> plus <count> is greater than the number of program local parameters supported by <target>.

New State

None.

Issues

*(1) Should a set of ProgramEnvParameters*EXT() calls be added, or is using NV_vertex_program's ProgramParameters*NV() sufficient?*

RESOLVED: We should add an ARB-style ProgramEnvParameters*() call for naming consistency. Also ProgramParameters*NV() are not available on all platforms.

(2) Should an equivalent set of calls be added to query multiple program parameters at once?

RESOLVED: No.

(3) Should double-precision versions be supported?

RESOLVED: No. Double-precision parameter values will be converted to single-precision in current driver implementations, anyway.

(4) Why is this spec called "EXT_gpu_program_parameters"?

RESOLVED: The functionality provided by this spec applies to more than one program type. The term "GPU" was used in the extension name to indicate functionality common to all supported program types, which are commonly executed on a GPU.

(5) Is it an error to load multiple parameters with a <count> of zero?

RESOLVED: No. However, it was illegal in versions of the spec prior to 9/27/07. The spec was changed to resolve differences between the shipping implementations from NVIDIA (which did enforce the error) and Apple (which did not). The new behavior is more consistent with the standard OpenGL practice of allowing zero to be passed to GLsizei parameters, and avoids the need for special-case behavior to handle/avoid zero counts in both drivers and applications. Since loading zero program parameters has no actual effect, the only difference between the two behaviors is the update of the GL error state.

Revision History

```
Rev.    Date     Author    Changes
----  --------  --------  -----------------------------------------
6     09/27/07  pbrown    Change the spec to indicate that it's not
                          illegal to load zero parameters, just
                          pointless.

5     11/06/06  mjk       Indicate shipping

4     06/28/06  barthold  Make clear that this spec modifies both
                          ARB_vertex_program and ARB_fragment_program.

3     06/27/06  pbrown    Fix incorrect error language in checking the
                          sum of <index> and <count>, added an issue
                          about the spec name.

2     06/02/06  haroon    Changed to EXT. Added contributors.

Dependencies

    OpenGL 2.0 is required.

    This extension is written against the OpenGL 2.0 specification and version
    1.10.59 of the OpenGL Shading Language specification.

    This extension trivially interacts with ARB_texture_rectangle.

    This extension trivially interacts with GL_EXT_texture_array.

    This extension trivially interacts with GL_EXT_texture_integer.

    This extension trivially interacts with GL_EXT_geometry_shader4

    This extension trivially interacts with GL_EXT_texture_buffer_object.

    NV_primitive_restart trivially affects the definition of this extension.

    ARB_color_buffer_float affects the definition of this extension.
    EXT_draw_instanced affects the definition of this extension.

Overview

    This extension provides a set of new features to the OpenGL Shading
    Language and related APIs to support capabilities of new hardware. In
    particular, this extension provides the following functionality:

       * New texture lookup functions are provided that allow shaders to

access individual texels using integer coordinates referring to the texel location and level of detail. No filtering is performed. These functions allow applications to use textures as one-, two-, and three-dimensional arrays.

* New texture lookup functions are provided that allow shaders to query the dimensions of a specific level-of-detail image of a texture object.

* New texture lookup functions variants are provided that allow shaders to pass a constant integer vector used to offset the texel locations used during the lookup to assist in custom texture filtering operations.

* New texture lookup functions are provided that allow shaders to access one- and two-dimensional array textures. The second, or third, coordinate is used to select the layer of the array to access.

* New "Grad" texture lookup functions are provided that allow shaders to explicitely pass in derivative values which are used by the GL to compute the level-of-detail when performing a texture lookup.

* A new texture lookup function is provided to access a buffer texture.

* The existing absolute LOD texture lookup functions are no longer restricted to the vertex shader only.

* The ability to specify and use cubemap textures with a DEPTH_COMPONENT internal format. This also enables shadow mapping on cubemaps. The 'q' coordinate is used as the reference value for comparisons. A set of new texture lookup functions is provided to lookup into shadow cubemaps.

* The ability to specify if varying variables are interpolated in a non-perspective correct manner, if they are flat shaded or, if multi-sampling, if centroid sampling should be performed.

* Full signed integer and unsigned integer support in the OpenGL Shading Language:

    - Integers are defined as 32 bit values using two's complement.

    - Unsigned integers and vectors thereof are added.

    - New texture lookup functions are provided that return integer values. These functions are to be used in conjunction with new texture formats whose components are actual integers, rather than integers that encode a floating-point value. To support these lookup functions, new integer and unsigned-integer sampler types are introduced.

    - Integer bitwise operators are now enabled.

    - Several built-in functions and operators now operate on integers or vectors of integers.

```
            - New vertex attribute functions are added that load integer
              attribute data and can be referenced in a vertex shader as
              integer data.

            - New uniform loading commands are added to load unsigned integer
              data.

            - Varying variables can now be (unsigned) integers. If declared
              as such, they have to be flat shaded.

            - Fragment shaders can define their own output variables, and
              declare them to be of type floating-point, integer or unsigned
              integer. These variables are bound to a fragment color index
              with the new API command BindFragDataLocationEXT(), and directed
              to buffers using the existing DrawBuffer or DrawBuffers API
              commands.

        * Added new built-in functions truncate() and round() to the shading
          language.

        * A new built-in variable accessible from within vertex shaders that
          holds the index <i> implicitly passed to ArrayElement to specify the
          vertex. This is called the vertex ID.

        * A new built-in variable accessible from within fragment and geometry
          shaders that hold the index of the currently processed
          primitive. This is called the primitive ID.

    This extension also briefly mentions a new shader type, called a geometry
    shader. A geometry shader is run after vertices are transformed, but
    before clipping. A geometry shader begins with a single primitive (point,
    line, triangle. It can read the attributes of any of the vertices in the
    primitive and use them to generate new primitives. A geometry shader has a
    fixed output primitive type (point, line strip, or triangle strip) and
    emits vertices to define a new primitive. Geometry shaders are discussed
    in detail in the GL_EXT_geometry_shader4 specification.
```

New Procedures and Functions

```
    void VertexAttribI1iEXT(uint index, int x);
    void VertexAttribI2iEXT(uint index, int x, int y);
    void VertexAttribI3iEXT(uint index, int x, int y, int z);
    void VertexAttribI4iEXT(uint index, int x, int y, int z, int w);

    void VertexAttribI1uiEXT(uint index, uint x);
    void VertexAttribI2uiEXT(uint index, uint x, uint y);
    void VertexAttribI3uiEXT(uint index, uint x, uint y, uint z);
    void VertexAttribI4uiEXT(uint index, uint x, uint y, uint z,
                             uint w);

    void VertexAttribI1ivEXT(uint index, const int *v);
    void VertexAttribI2ivEXT(uint index, const int *v);
    void VertexAttribI3ivEXT(uint index, const int *v);
    void VertexAttribI4ivEXT(uint index, const int *v);
    void VertexAttribI1uivEXT(uint index, const uint *v);
    void VertexAttribI2uivEXT(uint index, const uint *v);
    void VertexAttribI3uivEXT(uint index, const uint *v);
    void VertexAttribI4uivEXT(uint index, const uint *v);

    void VertexAttribI4bvEXT(uint index, const byte *v);
    void VertexAttribI4svEXT(uint index, const short *v);
    void VertexAttribI4ubvEXT(uint index, const ubyte *v);
    void VertexAttribI4usvEXT(uint index, const ushort *v);

    void VertexAttribIPointerEXT(uint index, int size, enum type,
                                 sizei stride, const void *pointer);

    void GetVertexAttribIivEXT(uint index, enum pname, int *params);
    void GetVertexAttribIuivEXT(uint index, enum pname,
                                uint *params);

    void Uniform1uiEXT(int location, uint v0);
    void Uniform2uiEXT(int location, uint v0, uint v1);
    void Uniform3uiEXT(int location, uint v0, uint v1, uint v2);
    void Uniform4uiEXT(int location, uint v0, uint v1, uint v2,
                       uint v3);

    void Uniform1uivEXT(int location, sizei count, const uint *value);
    void Uniform2uivEXT(int location, sizei count, const uint *value);
    void Uniform3uivEXT(int location, sizei count, const uint *value);
    void Uniform4uivEXT(int location, sizei count, const uint *value);

    void GetUniformuivEXT(uint program, int location, uint *params);

    void BindFragDataLocationEXT(uint program, uint colorNumber,
                                 const char *name);
    int GetFragDataLocationEXT(uint program, const char *name);
```

New Tokens

    Accepted by the <pname> parameters of GetVertexAttribdv,
    GetVertexAttribfv, GetVertexAttribiv, GetVertexAttribIuivEXT and
    GetVertexAttribIivEXT:

```
      VERTEX_ATTRIB_ARRAY_INTEGER_EXT                    0x88FD
```

Returned by the <type> parameter of GetActiveUniform:

SAMPLER_1D_ARRAY_EXT	0x8DC0
SAMPLER_2D_ARRAY_EXT	0x8DC1
SAMPLER_BUFFER_EXT	0x8DC2
SAMPLER_1D_ARRAY_SHADOW_EXT	0x8DC3
SAMPLER_2D_ARRAY_SHADOW_EXT	0x8DC4
SAMPLER_CUBE_SHADOW_EXT	0x8DC5
UNSIGNED_INT	0x1405
UNSIGNED_INT_VEC2_EXT	0x8DC6
UNSIGNED_INT_VEC3_EXT	0x8DC7
UNSIGNED_INT_VEC4_EXT	0x8DC8
INT_SAMPLER_1D_EXT	0x8DC9
INT_SAMPLER_2D_EXT	0x8DCA
INT_SAMPLER_3D_EXT	0x8DCB
INT_SAMPLER_CUBE_EXT	0x8DCC
INT_SAMPLER_2D_RECT_EXT	0x8DCD
INT_SAMPLER_1D_ARRAY_EXT	0x8DCE
INT_SAMPLER_2D_ARRAY_EXT	0x8DCF
INT_SAMPLER_BUFFER_EXT	0x8DD0
UNSIGNED_INT_SAMPLER_1D_EXT	0x8DD1
UNSIGNED_INT_SAMPLER_2D_EXT	0x8DD2
UNSIGNED_INT_SAMPLER_3D_EXT	0x8DD3
UNSIGNED_INT_SAMPLER_CUBE_EXT	0x8DD4
UNSIGNED_INT_SAMPLER_2D_RECT_EXT	0x8DD5
UNSIGNED_INT_SAMPLER_1D_ARRAY_EXT	0x8DD6
UNSIGNED_INT_SAMPLER_2D_ARRAY_EXT	0x8DD7
UNSIGNED_INT_SAMPLER_BUFFER_EXT	0x8DD8

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

MIN_PROGRAM_TEXEL_OFFSET_EXT	0x8904
MAX_PROGRAM_TEXEL_OFFSET_EXT	0x8905

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

Modify Section 2.7 "Vertex Specification", p.20

Insert before last paragraph, p.22:

The VertexAttrib* commands described so far should not be used to load data for vertex attributes declared as signed or unsigned integers or vectors thereof in a vertex shader. If they are used to load signed or unsigned integer vertex attributes, the value in those attributes are undefined. Instead use the commands

```
void VertexAttribI[1234]{i,ui}EXT(uint index, T values);
void VertexAttribI[1234]{i,ui}vEXT(uint index, T values);
void VertexAttribI4{b,s,ub,us}vEXT(uint index, T values);
```

to specify fixed-point attributes that are not converted to floating-point. These attributes can be accessed in vertex shaders that declare attributes as signed or unsigned integers or vectors. The VertexAttribI4* commands extend the data passed in to a full signed or unsigned integer. If a VertexAttribI* command is used that does not match the type of the attribute declared in a vertex shader, the values in the attributes are undefined. This means that the unsigned versions of the VertexAttribI* commands need to be used to load data for unsigned integer vertex attributes or vectors, and the signed versions of the VertexAttribI* commands for signed integer vertex attributes or vectors. Note that this also means that the VertexAttribI* commands should not be used to load data for a vertex attribute declared as a float, float vector or matrix, otherwise their values are undefined.

Insert at end of function list, p.24:

```
void VertexAttribIPointerEXT(uint index, int size, enum type,
                             sizei stride, const void *pointer);
```

(modify last paragraph, p.24) The <index> parameter in the VertexAttribPointer and VertexAttribIPointerEXT commands identify the generic vertex attribute array being described. The error INVALID_VALUE is generated if <index> is greater than or equal to MAX_VERTEX_ATTRIBS. Generic attribute arrays with integer <type> arguments can be handled in one of three ways: converted to float by normalizing to [0,1] or [-1,1] as specified in table 2.9, converted directly to float, or left as integers. Data for an array specified by VertexAttribPointer will be converted to floating-point by normalizing if the <normalized> parameter is TRUE, and converted directly to floating-point otherwise. Data for an array specified by VertexAttribIPointerEXT will always be left as integer values.

(modify Table 2.4, p. 25)

Command	Sizes	Integer Handling	Types
VertexPointer	2,3,4	cast	...
NormalPointer	3	normalize	...
ColorPointer	3,4	normalize	...
SecondaryColorPointer	3	normalize	...
IndexPointer	1	cast	...
FogCoordPointer	1	n/a	...
TexCoordPointer	1,2,3,4	cast	...
EdgeFlagPointer	1	integer	...
VertexAttribPointer	1,2,3,4	flag	...
VertexAttribIPointerEXT	1,2,3,4	integer	byte, ubyte, short, ushort, int, uint

Table 2.4: Vertex array sizes (values per vertex) and data types. The "integer handling" column indicates how fixed-point data types are handled: "cast" means that they converted to floating-point directly, "normalize" means that they are converted to floating-point by normalizing to [0,1] (for unsigned types) or [-1,1] (for signed types), "integer" means that they remain as integer values, and "flag" means that either "cast" or "normalized" applies, depending on the setting of the <normalized> flag in VertexAttribPointer.

(modify end of pseudo-code, pp. 27-28)

```
  for (j = 1; j < genericAttributes; j++) {
    if (generic vertex attribute j array enabled) {
      if (generic vertex attribute j array is a pure integer array)
      {
        VertexAttribI[size][type]vEXT(j, generic vertex attribute j
                                         array element i);
      } else if (generic vertex attribute j array normalization
                 flag is set and <type> is not FLOAT or DOUBLE) {
        VertexAttrib[size]N[type]v(j, generic verex attribute j
                                      array element i);
      } else {
        VertexAttrib[size][type]v(j, generic verex attribute j
                                     array element i);
      }
    }
  }

  if (generic vertex attribute 0 array enabled) {
    if (generic vertex attribute 0 array is a pure integer array) {
      VertexAttribI[size][type]vEXT(0, generic verex attribute 0
                                       array element i);
    } else if (generic vertex attribute 0 array normalization flag
               is set and <type> is not FLOAT or DOUBLE) {
     VertexAttrib[size]N[type]v(0, generic verex attribute 0
                                   array element i);
    } else {
      VertexAttrib[size][type]v(0, generic verex attribute 0
                                   array element i);
    }
  }
```

Modify section 2.14.7, "Flatshading", p. 69

Add a new paragraph at the end of the section on p. 70 as follows:

If a vertex or geometry shader is active, the flat shading control described so far applies to the built-in varying variables gl_FrontColor, gl_BackColor, gl_FrontSecondaryColor and gl_BackSecondaryColor. Through the OpenGL Shading Language varying qualifier flat any vertex attribute can be flagged to be flat-shaded. See the OpenGL Shading Language Specification section 4.3.6 for more information.

Modify section 2.14.8, "Color and Associated Data Clipping", p. 71

Add to the end of this section:

For vertex shader varying variables specified to be interpolated without perspective correction (using the noperspective keyword), the value of t used to obtain the varying value associated with P will be adjusted to produce results that vary linearly in screen space.

Modify section 2.15.3, "Shader Variables", page 75

Add the following new return types to the description of GetActiveUniform on p. 81.

```
  SAMPLER_1D_ARRAY_EXT,
  SAMPLER_2D_ARRAY_EXT,
  SAMPLER_1D_ARRAY_SHADOW_EXT,
  SAMPLER_2D_ARRAY_SHADOW_EXT,
  SAMPLER_CUBE_SHADOW_EXT,
  SAMPLER_BUFFER_EXT,

  INT_SAMPLER_1D_EXT,
  INT_SAMPLER_2D_EXT,
  INT_SAMPLER_3D_EXT,
  INT_SAMPLER_CUBE_EXT,
  INT_SAMPLER_2D_RECT_EXT,
  INT_SAMPLER_1D_ARRAY_EXT,
  INT_SAMPLER_2D_ARRAY_EXT,
  INT_SAMPLER_BUFFER_EXT,

  UNSIGNED_INT,
  UNSIGNED_INT_VEC2_EXT,
  UNSIGNED_INT_VEC3_EXT,
  UNSIGNED_INT_VEC4_EXT,
  UNSIGNED_INT_SAMPLER_1D_EXT,
  UNSIGNED_INT_SAMPLER_2D_EXT,
  UNSIGNED_INT_SAMPLER_3D_EXT,
  UNSIGNED_INT_SAMPLER_CUBE_EXT,
  UNSIGNED_INT_SAMPLER_2D_RECT_EXT,
  UNSIGNED_INT_SAMPLER_1D_ARRAY_EXT,
  UNSIGNED_INT_SAMPLER_2D_ARRAY_EXT,
  UNSIGNED_INT_SAMPLER_BUFFER_EXT.
```

Add the following uniform loading command prototypes on p. 81 as follows:

```
  void Uniform{1234}uiEXT(int location, T value);
  void Uniform{1234}uivEXT(int location, sizei count, T value);
```

(add the following paragraph to the description of the above commands)

The Uniform*ui{v} commands will load count sets of one to four unsigned integer values into a uniform location defined as a unsigned integer, an unsigned integer vector, an array of unsigned integers or an array of unsigned integer vectors.

(change the first sentence of the last paragraph as follows)

When loading values for a uniform declared as a Boolean, the Uniform*i{v}, Uniform*ui{v} and Uniform*f{v} set of commands can be used to load boolean values.

Modify section 2.15.4 Shader execution, p. 84.

Add a new section "2.15.4.1 Shader Only Texturing" before the sub-section "Texture Access" on p. 85

This section describes texture functionality that is only accessible through vertex, geometry or fragment shaders. Also refer to the OpenGL Shading Language Specification, section 8.7 and Section 3.8 of the OpenGL 2.0 specification.

Note: For unextended OpenGL 2.0 and the OpenGL Shading Language version 1.20, all supported texture internal formats store unsigned integer values but return floating-point results in the range [0, 1] and are considered unsigned "normalized" integers. The ARB_texture_float extension introduces floating-point internal format where components are both stored and returned as floating-point values, and are not clamped. The EXT_texture_integer extension introduces formats that store either signed or unsigned integer values.

This extension defines additional OpenGL Shading Language texture lookup functions, see section 8.7 of the OpenGL Shading Language, that return either signed or unsigned integer values if the internal format of the texture is signed or unsigned, respectively.

Texel Fetches

The OpenGL Shading Language texel fetch functions provide the ability to extract a single texel from a specified texture image. The integer coordinates passed to the texel fetch functions are used directly as the texel coordinates (i, j, k) into the texture image. This in turn means the texture image is point-sampled (no filtering is performed).

The level of detail accessed is computed by adding the specified level-of-detail parameter <lod> to the base level of the texture, level_base.

The texel fetch functions can not perform depth comparisons or access cube maps. Unlike filtered texel accesses, texel fetches do not support LOD clamping or any texture wrap mode, and require a mipmapped minification filter to access any level of detail other than the base level.

The results of the texel fetch are undefined:

* if the computed LOD is less than the texture's base level (level_base) or greater than the maximum level (level_max),

* if the computed LOD is not the texture's base level and the texture's minification filter is NEAREST or LINEAR,

* if the layer specified for array textures is negative or greater than the number of layers in the array texture,

* if the texel at (i,j,k) coordinates refer to a border texel outside the defined extents of the specified LOD, where

```
        i < -b_s, j < -b_s, k < -b_s,
        i >= w_s - b_s, j >= h_s - b_s, or k >= d_s - b_s,
```

  where the size parameters (w_s, h_s, d_s, and b_s) refer to the width, height, depth, and border size of the image, as in equations 3.15, 3.16, and 3.17, or

. if the texture being accessed is not complete (or cube complete for cubemaps).

Texture Size Query

The OpenGL Shading Language texture size functions provide the ability to query the size of a texture image. The LOD value <lod> passed in as an argument to the texture size functions is added to the level_base of the texture to determine a texture image level. The dimensions of that image level, excluding a possible border, are then returned. If the computed texture image level is outside the range [level_base, level_max], the results are undefined. When querying the size of an array texture, both the dimensions and the layer index are returned. Note that buffer textures do not support mipmapping, therefore the previous lod discussion does not apply to buffer textures

Make the section "Texture Access" a subsection of 2.15.4.1

Modify the first paragraph on p. 86 as follows:

Texture lookups involving textures with depth component data can either return the depth data directly or return the results of a comparison with the R value (see section 3.8.14) used to perform the lookup. The comparison operation is requested in the shader by using any of the shadow sampler and in the texture using the TEXTURE COMPARE MODE parameter. These requests must be consistent; the results of a texture lookup are undefined if:

* The sampler used in a texture lookup function is not one of the shadow sampler types, and the texture object's internal format is DEPTH COMPONENT, and the TEXTURE COMPARE MODE is not NONE.

* The sampler used in a texture lookup function is one of the shadow sampler types, and the texture object's internal format is DEPTH COMPONENT, and the TEXTURE COMPARE MODE is NONE.

* The sampler used in a texture lookup function is one of the shadow sampler types, and the texture object's internal format is not DEPTH COMPONENT.

Add a new section "2.15.4.2 Shader Inputs" before "Position Invariance" on p. 86

Besides having access to vertex attributes and uniform variables, vertex shaders can access the read-only built-in variables gl_VertexID and gl_InstanceID. The gl_VertexID variable holds the integer index <i> implicitly passed to ArrayElement() to specify the vertex. The variable gl_InstanceID holds the integer index of the current primitive in an instanced draw call. See also section 7.1 of the OpenGL Shading Language Specification.

Add a new section "2.15.4.3 Shader Outputs"

A vertex shader can write to built-in as well as user-defined varying variables. These values are expected to be interpolated across the primitive it outputs, unless they are specified to be flat shaded. Refer to section 2.15.3 and the OpenGL Shading Language specification sections 4.3.6, 7.1 and 7.6 for more detail.

The built-in output variables gl_FrontColor, gl_BackColor, gl_FrontSecondaryColor, and gl_BackSecondaryColor hold the front and back colors for the primary and secondary colors for the current vertex.

The built-in output variable gl_TexCoord[] is an array and holds the set of texture coordinates for the current vertex.

The built-in output variable gl_FogFragCoord is used as the "c" value, as described in section 3.10 "Fog" of the OpenGL 2.0 specification.

The built-in special variable gl_Position is intended to hold the homogeneous vertex position. Writing gl_Position is optional.

The built-in special variable gl_ClipVertex holds the vertex coordinate used in the clipping stage, as described in section 2.12 "Clipping" of the OpenGL 2.0 specification.

The built in special variable gl_PointSize, if written, holds the size of the point to be rasterized, measured in pixels.

Number section "Position Invariance", "Validation" and "Undefined Behavior" as sections 2.15.4.4, 2.15.4.5, and 2.15.4.6 respectively.

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

Modify Section 3.8.1, Texture Image Specification, p. 150

(modify 4th paragraph, p. 151 -- add cubemaps to the list of texture targets that can be used with DEPTH_COMPONENT textures)

Textures with a base internal format of DEPTH_COMPONENT are supported by texture image specification commands only if <target> is TEXTURE_1D, TEXTURE_2D, TEXTURE_CUBE_MAP, TEXTURE_RECTANGLE_ARB, PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_CUBE_MAP, or PROXY_TEXTURE_RECTANGLE_ARB. Using this format in conjunction with any other target will result in an INVALID_OPERATION error.

Modify Section 3.8.8, Texture Minification:

(replace the last paragraph, p. 171): Let s(x,y) be the function that associates an s texture coordinate with each set of window coordinates (x,y) that lie within a primitive; define t(x,y) and r(x,y) analogously.

```
    Let

          u(x,y) = w_t * s(x,y)
          v(x,y) = h_t * t(x,y)    (3.20a)
          w(x,y) = d_t * r(x,y)

    where w_t, h_t, and d_t are as defined by equations 3.15, 3.16, and 3.17
    with w_s, h_s, and d_s equal to the width, height, and depth of the image
    array whose level is level_base. For a one-dimensional texture, define
    v(x,y) == 0 and w(x,y) == 0; for two-dimensional textures, define w(x,y)
    == 0.

    (start a new paragraph with "For a polygon, rho is given at a fragment
    with window coordinates...", and then continue with the original spec
    text.)

    (replace text starting with the last paragraph on p. 172,
    continuing to the end of p. 174)

    The (u,v,w) coordinates are then modified, as follows:

          u'(x,y) = u(x,y) + offsetu_shader,
          v'(x,y) = v(x,y) + offsetv_shader,
          w'(x,y) = w(x,y) + offsetw_shader

    where (offsetu_shader, offsetv_shader, offsetw_shader) is the texel offset
    specified in the OpenGL Shading Language texture lookup functions that
    support offsets. If the texture function used does not support offsets, or
    for fixed-function texture accesses, all three shader offsets are taken to
    be zero.

    The (u',v',w') coordinates are then further modified according the texture
    wrap modes, as specified in Table X.19, to generate a new set of
    coordinates (u'',v'',w'').
```

```
  TEXTURE_WRAP_S              Coordinate Transformation
  --------------------------  -------------------------------------
  CLAMP                       u'' = clamp(u', 0, w_t-0.5),
                                     if NEAREST filtering,
                                    clamp(u', 0, w_t),
                                     otherwise
  CLAMP_TO_EDGE               u'' = clamp(u', 0.5, w_t-0.5)
  CLAMP_TO_BORDER             u'' = clamp(u', -0.5, w_t+0.5)
  REPEAT                      u'' = clamp(fmod(u', w_t), 0.5, w_t-0.5)
  MIRROR_CLAMP_EXT            u'' = clamp(fabs(u'), 0.5, w_t-0.5),
                                     if NEAREST filtering, or
                                  = clamp(fabs(u'), 0.5, w_t),
                                     otherwise
  MIRROR_CLAMP_TO_EDGE_EXT    u'' = clamp(fabs(u'), 0.5, w_t-0.5)
  MIRROR_CLAMP_TO_BORDER_EXT  u'' = clamp(fabs(u'), 0.5, w_t+0.5)
  MIRRORED_REPEAT             u'' = w_t -
                                    clamp(fabs(w_t - fmod(u', 2*w_t)),
                                         0.5, w_t-0.5)
```

Table X.19: Texel coordinate wrap mode application. clamp(a,b,c) returns b if a<b, c if a>c, and a otherwise. fmod(a,b) returns a-b*floor(a/b), and fabs(a) returns the absolute value of a. For the v and w coordinates, TEXTURE_WRAP_T and h_t, and TEXTURE_WRAP_R and d_t, respectively, are used.

When lambda indicates minification, the value assigned to TEXTURE_MIN_FILTER is used to determine how the texture value for a fragment is selected.

When TEXTURE_MIN_FILTER is NEAREST the texel in the image array of level level_base that is nearest (in Manhattan distance) to (u'',v'',w'') is obtained. The coordinate (i,j,k) is then computed as (floor(u''), floor(v''), floor(w'')).

For a three-dimensional texture, the texel at location (i,j,k) becomes the texture value. For a two-dimensional texture, k is irrelevant, and the texel at location (i,j) becomes the texture value. For a one-dimensional texture, j and k are irrelevant, and the texel at location i becomes the texture value.

If the selected (i,j,k), (i,j), or i location refers to a border texel that satisfies any of the following conditions:

```
      i < -b_s,
      j < -b_s,
      k < -b_s,
      i >= w_l + b_s,
      j >= h_l + b_s, or
      j >= d_l + b_s,
```

then the border values defined by TEXTURE_BORDER_COLOR are used in place of the non-existent texel. If the texture contains color components, the values of TEXTURE_BORDER_COLOR are interpreted as an RGBA color to match the texture's internal format in a manner consistent with table 3.15. If the texture contains depth components, the first component of TEXTURE_BORDER_COLOR is interpreted as a depth value.

When TEXTURE_MIN_FILTER is LINEAR, a 2x2x2 cube of texels in the image array of level level_base is selected. Let:

```
      i_0   = floor(u'' - 0.5),
      j_0   = floor(v'' - 0.5),
      k_0   = floor(w'' - 0.5),
      i_1   = i_0 + 1,
      j_1   = j_0 + 1,
      k_1   = k_0 + 1,
      alpha = frac(u'' - 0.5),
      beta  = frac(v'' - 0.5), and
      gamma = frac(w'' - 0.5),
```

For a three-dimensional texture, the texture value tau is found as...

(replace last paragraph, p.174) For any texel in the equation above that refers to a border texel outside the defined range of the image, the texel value is taken from the texture border color as with NEAREST filtering.

Rename section 3.8.9 "Texture Magnification" to section 3.8.8

modify the first paragraph of section 3.8.8 "Texture Magnification" as follows:

When lambda indicates magnification, the value assigned to TEXTURE_MAG_FILTER determines how the texture value is obtained. There are two possible values for TEXTURE_MAG_FILTER: NEAREST and LINEAR. NEAREST behaves exactly as NEAREST for TEXTURE_MIN_FILTER and LINEAR behaves exactly as LINEAR for TEXTURE_MIN_FILTER, as described in the previous section, including the wrapping calculations. The level-of-detail level_base texture array is always used for magnification.

modify the last paragraph of section 3.8.8, p. 175, as follows:

The rules for NEAREST or LINEAR filtering are then applied to the selected array. Specifically, the coordinate (u,v,w) is computed as in equation 3.20a, with w_s, h_s, and d_s equal to the width, height, and depth of the image array whose level is 'd'.

Modify the second paragraph on p. 176

The rules for NEAREST or LINEAR filtering are then applied to each of the selected arrays, yielding two corresponding texture valutes Tau1 and Tau2. Specifically, for level d1, the coordinate (u,v,w) is computed as in equation 3.20a, with w_s, h_s, and d_s equal to the width, height, and depth of the image array whose level is 'd1'. For level d2 the coordinate (u', v', w') is computed as in equation 3.20a, with w_s, h_s, and d_s equal to the width, height, and depth of the image array whose level is 'd2'.

Modify Section 3.8.14, Texture Comparison Modes (p. 185)

(modify 2nd paragraph, p. 188, indicating that the Q texture coordinate is used for depth comparisons on cubemap textures)

Let D_t be the depth texture value, in the range [0, 1]. For fixed-function texture lookups, let R be the interpolated <r> texture coordinate, clamped to the range [0, 1]. For texture lookups generated by an OpenGL Shading Language lookup function, let R be the reference value for depth comparisons provided in the lookup function, also clamped to [0, 1]. Then the effective texture value L_t, I_t, or A_t is computed as follows:

Modify section 3.11, Fragment Shaders, p. 193

Modify the third paragraph on p. 194 as follows:

Additionally, when a vertex shader is active, it may define one or more varying variables (see section 2.15.3 and the OpenGL Shading Language Specification). These values are, if not flat shaded, interpolated across the primitive being rendered. The results of these interpolations are available when varying variables of the same name are defined in the fragment shader.

Add the following paragraph to the end of section 3.11.1, p. 194

A fragment shader can also write to varying out variables. Values written to these variables are used in the subsequent per-fragment operations. Varying out variables can be used to write floating-point, integer or unsigned integer values destined for buffers attached to a framebuffer object, or destined for color buffers attached to the default framebuffer. The subsection 'Shader Outputs' of the next section describes API how to direct these values to buffers.

Add a new paragraph at the beginning of the section "Texture Access", p. 194

Section 2.15.4.1 describes texture lookup functionality accessible to a vertex shader. The texel fetch and texture size query functionality described there also applies to fragment shaders.

Modify the second paragraph on p. 195 as follows:

Texture lookups involving textures with depth component data can either return the depth data directly or return the results of a comparison with the R value (see section 3.8.14) used to perform the lookup. The comparison operation is requested in the shader by using any of the shadow sampler and in the texture using the TEXTURE COMPARE MODE parameter. These requests must be consistent; the results of a texture lookup are undefined if:

* The sampler used in a texture lookup function is not one of the shadow sampler types, and the texture object's internal format is DEPTH COMPONENT, and the TEXTURE COMPARE MODE is not NONE.

* The sampler used in a texture lookup function is one of the shadow sampler types, and the texture object's internal format is DEPTH COMPONENT, and the TEXTURE COMPARE MODE is NONE.

* The sampler used in a texture lookup function is one of the shadow sampler types, and the texture object's internal format is not DEPTH COMPONENT.

Add the following paragraph to the section Shader Inputs, p. 196

If a geometry shader is active, the built-in variable gl_PrimitiveID contains the ID value emitted by the geometry shader for the provoking vertex. If no geometry shader is active, gl_PrimitiveID is filled with the number of primitives processed by the rasterizer since the last time Begin was called (directly or indirectly via vertex array functions). The first primitive generated after a Begin is numbered zero, and the primitive ID counter is incremented after every individual point, line, or polygon primitive is processed. For polygons drawn in point or line mode, the primitive ID counter is incremented only once, even though multiple points or lines may be drawn. For QUADS and QUAD_STRIP primitives that are decomposed into triangles, the primitive ID is incremented after each complete quad is processed. For POLYGON primitives, the primitive ID counter is undefined. The primitive ID is undefined for fragments generated by DrawPixels or Bitmap. Restarting a primitive topology using the primitive restart index has no effect on the primitive ID counter.

Modify the first paragraph of the section Shader Outputs, p. 196 as follows

The OpenGL Shading Language specification describes the values that may be output by a fragment shader. These outputs are split into two categories. User-defined varying out variables and built-in variables. The built-in variables are gl_FragColor, gl_FragData[n], and gl_FragDepth. If fragment clamping is enabled, the final fragment color values or the final fragment data values or the final varying out variable values written by a fragment shader are clamped to the range [0,1] and then may be converted to fixed-point as described in section 2.14.9. Only user-defined varying out variables declared as a floating-point type are clamped and may be converted. If fragment clamping is disabled, the final fragment color values or the final fragment data values or the final varying output variable values are not modified. The final fragment depth written...

Modify the second paragraph of the section Shader Outputs, p. 196 as follows

...A fragment shader may not statically assign values to more than one of gl_FragColor, gl_FragData or any user-defined varying output variable. In this case, a compile or link error will result. A shader statically...

Add the following to the end of the section Shader Outputs, p. 197

The values of user-defined varying out variables are directed to a color buffer in a two step process. First the varying out variable is bound to a fragment color by using its number. The GL will assign a number to each varying out variable, unless overridden by the command BindFragDataLocationEXT(). The number of the fragment color assigned for each user-defined varying out variable can be queried with GetFragDataLocationEXT(). Next, the DrawBuffer or DrawBuffers commands (see section 4.2.1) direct each fragment color to a particular buffer.

The binding of a user-defined varying out variable to a fragment color number can be specified explicitly. The command

```
    void BindFragDataLocationEXT(uint program, uint colorNumber,
                                 const char *name);
```

specifies that the varying out variable name in program should be bound to fragment color colorNumber when the program is next linked. If name was bound previously, its assigned binding is replaced with colorNumber. name must be a null terminated string. The error INVALID_VALUE is generated if colorNumber is equal or greater than MAX_DRAW_BUFFERS. BindFragDataLocationEXT has no effect until the program is linked. In particular, it doesn't modify the bindings of varying out variables in a program that has already been linked. The error INVALID OPERATION is generated if name starts with the reserved "gl_" prefix.

When a program is linked, any varying out variables without a binding specified through BindFragDataLocationEXT will automatically be bound to fragment colors by the GL. Such bindings can be queried using the command GetFragDataLocationEXT. LinkProgram will fail if the assigned binding of a varying out variable would cause the GL to reference a non-existant fragment color number (one greater than or equal to MAX DRAW_BUFFERS). LinkProgram will also fail if more than one varying out variable is bound to the same number. This type of aliasing is not allowed.

BindFragDataLocationEXT may be issued before any shader objects are attached to a program object. Hence it is allowed to bind any name (except a name starting with "gl_") to a color number, including a name that is never used as a varying out variable in any fragment shader object. Assigned bindings for variables that do not exist are ignored.

After a program object has been linked successfully, the bindings of varying out variable names to color numbers can be queried. The command

```
int GetFragDataLocationEXT(uint program, const char *name);
```

returns the number of the fragment color that the varying out variable name was bound to when the program object program was last linked. name must be a null terminated string. If program has not been successfully linked, the error INVALID OPERATION is generated. If name is not a varying out variable, or if an error occurs, -1 will be returned.

Additions to Chapter 4 of the OpenGL 2.0 Specification (Per-Fragment Operations and the Frame Buffer)

Modify Section 4.2.1, Selecting a Buffer for Writing (p. 212)

(modify next-to-last paragraph, p. 213) If a fragment shader writes to gl_FragColor, DrawBuffers specifies a set of draw buffers into which the single fragment color defined by gl_FragColor is written. If a fragment shader writes to gl_FragData or a user-defined varying out variable, DrawBuffers specifies a set of draw buffers into which each of the multiple output colors defined by these variables are separately written. If a fragment shader writes to neither gl_FragColor, nor gl FragData, nor any user-defined varying out variables, the values of the fragment colors following shader execution are undefined, and may differ for each fragment color.

Additions to Chapter 5 of the OpenGL 2.0 Specification (Special Functions)

Change section 5.4 Display Lists, p. 237

Add the commands VertexAttribIPointerEXT and BindFragDataLocationEXT to the list of commands that are not compiled into a display list, but executed immediately, under "Program and Shader Objects", p. 241

Additions to Chapter 6 of the OpenGL 2.0 Specification (State and State Requests)

Modify section 6.1.14 "Shader and Program Queries", p. 256

Modify 2nd paragraph, p.259:

Add the following to the list of GetVertexAttrib* commands:

```
  void GetVertexAttribIivEXT(uint index, enum pname, int *params);
  void GetVertexAttribIuivEXT(uint index, enum pname, uint *params);
```

obtain the... <pname> must be one of VERTEX_ATTRIB_ARRAY_ENABLED ,., VERTEX_ATTRIB_ARRAY_NORMALIZED, VERTEX_ATTRIB_ARRAY_INTEGER_EXT, or CURRENT_VERTEX_ATTRIB. ...

Split 3rd paragraph, p.259

... The size, stride, type, normalized flag, and unconverted integer flag are set by the commands VertexAttribPointer and VertexAttribIPointerEXT. The normalized flag is always set to FALSE by by VertexAttribIPointerEXT. The unconverted integer flag is always set to FALSE by VertexAttribPointer and TRUE by VertexAttribIPointerEXT.

The query CURRENT_VERTEX_ATTRIB returns the current value for the generic attribute <index>. GetVertexAttribdv and GetVertexAttribfv read and return the current attribute values as floating-point values; GetVertexAttribiv reads them as floating-point values and converts them to integer values; GetVertexAttribIivEXT reads and returns them as integers; GetVertexAttribIuivEXT reads and returns them as unsigned integers. The results of the query are undefined if the current attribute values are read using one data type but were specified using a different one. The error INVALID_OPERATION is generated if <index> is zero.

Change the prototypes in the first paragraph on page 260 as follows:

```
  void GetUniformfv(uint program, int location, float *params);
  void GetUniformiv(uint program, int location, int *params);
  void GetUniformuivEXT(uint program, int location, uint *params);
```

Additions to Appendix A of the OpenGL 2.0 Specification (Invariance)

None.

Additions to the AGL/GLX/WGL Specifications

None.

Interactions with GL_ARB_color_buffer_float

If the GL_ARB_color_buffer_float extension is not supported then any reference to fragment clamping in section 3.11.2 "Shader Execution" needs to be deleted.

Interactions with GL_ARB_texture_rectangle

If the GL_ARB_texture_rectangle extension is not supported then all references to texture lookup functions with 'Rect' in the name need to be deleted.

Interactions with GL_EXT_texture_array

If the GL_EXT_texture_array extension is not supported, all references to one- and two-dimensional array texture sampler types (e.g., sampler1DArray, sampler2DArray) and the texture lookup functions that use them need to be deleted.

Interactions with GL_EXT_geometry_shader4

If the GL_EXT_geometry_shader4 extension is not supported, all references to a geometry shader need to be deleted.

Interactions with GL_NV_primitive_restart

The spec describes the behavior that primitive restart does not affect the primitive ID counter, including for POLYGON primitives (where one could argue that the restart index starts a new primitive without a new Begin to reset the count). If NV_primitive_restart is not supported, references to that extension in the discussion of the primitive ID counter should be removed.

If NV_primitive_restart is supported, index values causing a primitive restart are not considered as specifying an End command, followed by another Begin. Primitive restart is therefore not guaranteed to immediately update material properties when a vertex shader is active. The spec language on p.64 of the OpenGL 2.0 specification says "changes are not guaranteed to update material parameters, defined in table 2.11, until the following End command."

Interactions with EXT_texture_integer

If the EXT_texture_integer spec is not supported, the discussion about this spec in section 2.15.4.1 needs to be removed. All texture lookup functions that return integers or unsigned integers, as discussed in section 8.7 of the OpenGL Shading Language specification, also need to be removed.

Interactions with EXT_texture_buffer_object

If EXT_texture_buffer_object is not supported, references to buffer textures, as well as the texelFetchBuffer and texelSizeBuffer lookup functions and samplerBuffer types, need to be removed.

Interactions with EXT_draw_instanced

If EXT_draw_instanced is not supported, the value of gl_InstanceID is always zero.

Errors

The error INVALID_VALUE is generated by BindFragDataLocationEXT() if colorNumber is equal or greater than MAX_DRAW_BUFFERS.

The error INVALID OPERATION is generated by BindFragDataLocationEXT() if name starts with the reserved "gl_" prefix.

The error INVALID_OPERATOIN is generated by BindFragDataLocationEXT() or GetFragDataLocationEXT if program is not the name of a program object.

The error INVALID_OPERATION is generated by GetFragDataLocationEXT() if program has not been successfully linked.

New State

(add to table 6.7, p. 268)

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
VERTEX_ATTRIB_ARRAY INTEGER_EXT	16+xB	GetVertexAttrib	FALSE	vertex attrib array has unconverted ints	2.8	vertex-array

New Implementation Dependent State

Get Value	Type	Get Command	Minimum Value	Description	Sec.	Attrib
MIN_PROGRAM_TEXEL_OFFSET_EXT	Z	GetIntegerv	-8	minimum texel offset allowed in lookup	2.x.4.4	-
MAX_PROGRAM_TEXEL_OFFSET_EXT	Z	GetIntegerv	+7	maximum texel offset allowed in lookup	2.x.4.4	-

Modifications to The OpenGL Shading Language Specification, Version 1.10.59

Including the following line in a shader can be used to control the language features described in this extension:

```
  #extension GL_EXT_gpu_shader4 : <behavior>
```

where <behavior> is as specified in section 3.3.

A new preprocessor #define is added to the OpenGL Shading Language:

```
  #define GL_EXT_gpu_shader4 1
```

Add to section 3.6 "Keywords"

Add the following keywords:

```
  noperspective, flat, centroid
```

Remove the unsigned keyword from the list of keywords reserved for future use, and add it to the list of keywords.

The following new vector types are added:

```
uvec2, uvec3, uvec4
```

The following new sampler types are added:

```
sampler1DArray, sampler2DArray, sampler1DArrayShadow,
sampler2DArrayShadow, samplerCubeShadow

isampler1D, isampler2D, isampler3D, isamplerCube, isampler2DRect,
isampler1DArray, isampler2DArray

usampler1D, usampler2D, usampler3D, usamplerCube, usampler2DRect,
usampler1DArray, usampler2DArray

samplerBuffer, isamplerBuffer, usamplerBuffer
```

Add to section 4.1 "Basic Types"

Break the table in this section up in several tables. The first table 4.1.1 is named "scalar, vector and matrix data types". It includes the first row through the 'mat4" row.

Add the following to the first section of this table:

unsigned int	An unsigned integer
uvec2	A two-component unsigned integer vector
uvec3	A three-component unsigned integer vector
uvec4	A four-component unsigned integer vector

Break out the sampler types in a separate table, and name that table 4.1.2 "default sampler types". Add the following sampler types to this new table:

sampler1DArray	handle for accessing a 1D array texture
sampler2DArray	handle for accessing a 2D array texture
sampler1DArrayShadow	handle for accessing a 1D array depth texture with comparison
sampler2DArrayShadow	handle for accessing a 2D array depth texture with comparison
samplerBuffer	handle for accessing a buffer texture

Add a table 4.1.3 called "integer sampler types":

isampler1D	handle for accessing an integer 1D texture
isampler2D	handle for accessing an integer 2D texture
isampler3D	handle for accessing an integer 3D texture
isamplerCube	handle for accessing an integer cube map texture
isampler2DRect	handle for accessing an integer rectangle texture
isampler1DArray	handle for accessing an integer 1D array texture
isampler2DArray	handle for accessing an integer 2D array texture
isamplerBuffer	handle for accessing an integer buffer texture

Add a table 4.1.4 called "unsigned integer sampler types":

usampler1D	handle for accessing an unsigned integer 1D texture
usampler2D	handle for accessing an unsigned integer 2D texture
usampler3D	handle for accessing an unsigned integer 3D texture
usamplerCube	handle for accessing an unsigned integer cube map texture
usampler2DRect	handle for accessing an unsigned integer rectangle texture
usampler1DArray	handle for accessing an unsigned integer 1D array texture
usampler2DArray	handle for accessing an unsigned integer 2D array texture
usamplerBuffer	handle for accessing an unsigned integer buffer texture

Change section 4.1.3 "Integers"

Remove the first two paragraphs and replace with the following:

Signed, as well as unsigned integers, are fully supported. Integers hold whole numbers. Integers have at least 32 bits of precision, including a sign bit. Signed integers are stored using a two's complement representation.

Integers are declared and optionally initialized with integer expressions as in the following example:

```
    int i, j = 42;
    unsigned int k = 3u;
```

Literal integer constants can be expressed in decimal (base 10), octal (base 8), or hexadecimal (base 16) as follows.

```
      integer-constant:
            decimal-constant integer-suffix_opt
            octal-constant integer-suffix_opt
            hexadecimal-constant integer-suffix_opt

      integer-suffix:  one of
            u U
```

Change section 4.3 "Type Qualifiers"

Change the "varying" and "out" qualifier as follows:

varying - linkage between a vertex shader and fragment shader, or between a fragment shader and the back end of the OpenGL pipeline.

out - for function parameters passed back out of a function, but not initialized for use when passed in. Also for output varying variables (fragment only).

In the qualifier table, add the following sub-qualifiers under the varying qualifier:

```
  flat varying
  noperspective varying
  centroid varying
```

Change section 4.3.4 "Attribute"

Change the sentence:

The attribute qualifier can be used only with the data types float, vec2, vec3, vec4, mat2, mat3, and mat4.

To:

The attribute qualifier can be used only with the data types int, ivec2, ivec3, ivec4, unsigned int, uvec2, uvec3, uvec4, float, vec2, vec3, vec4, mat2, mat3, and mat4.

Change the fourth paragraph to:

It is expected that graphics hardware will have a small number of fixed locations for passing vertex attributes. Therefore, the OpenGL Shading language defines each non-matrix attribute variable as having space for up to four integer or floating-point values (i.e., a vec4, ivec4 or uvec4). There is an implementation dependent limit on the number of attribute variables that can be used and if this is exceeded it will cause a link error. (Declared attribute variables that are not used do not count against this limit.) A scalar attribute counts the same amount against this limit as a vector of size four, so applications may want to consider packing groups of four unrelated scalar attributes together into a vector to better utilize the capabilities of the underlying hardware. A mat4 attribute will...

Change section 4.3.6 "Varying"

Change the first paragraph to:

Varying variables provide the interface between the vertex shader, the fragment shader, and the fixed functionality between the vertex and fragment shader, as well as the interface from the fragment shader to the back-end of the OpenGL pipeline.

The vertex shader will compute values per vertex (such as color, texture coordinates, etc.) and write them to variables declared with the varying qualifier. A vertex shader may also read varying variables, getting back the same values it has written. Reading a varying variable in a vertex shader returns undefined values if it is read before being written.

The fragment shader will compute values per fragment and write them to variables declared with the varying out qualifier. A fragment shader may also read varying variables, getting back the same result it has written. Reading a varying variable in a fragment shader returns undefined values if it is read before being written.

Varying variables may be written more than once. If so, the last value assigned is the one used.

Change the second paragraph to:

Varying variables that are set per vertex are interpolated by default in a perspective-correct manner over the primitive being rendered, unless the varying is further qualified with noperspective. Interpolation in a perspective correct manner is specified in equations 3.6 and 3.8 in the OpenGL 2.0 specification. When noperspective is specified, interpolation must be linear in screen space, as described in equation 3.7 and the approximation that follows equation 3.8.

If single-sampling, the value is interpolated to the pixel's center, and the centroid qualifier, if present, is ignored. If multi-sampling, and the varying is not qualified with centroid, then the value must be interpolated to the pixel's center, or anywhere within the pixel, or to one of the pixel's samples. If multi-sampling and the varying is qualified with centroid, then the value must be interpolated to a point that lies in both the pixel and in the primitive being rendered, or to one of the pixel's samples that falls within the primitive.

[NOTE: Language for centroid sampling taken from the GLSL 1.20.4 specification]

Varying variables, set per vertex, can be computed on a per-primitive basis (flat shading), or interpolated over a line or polygon primitive (smooth shading). By default, a varying variable is smooth shaded, unless the varying is further qualified with flat. When smooth shading, the varying is interpolated over the primitive. When flat shading, the varying is constant over the primitive, and is taken from the single provoking vertex of the primitive, as described in Section 2.14.7 of the OpenGL 2.0 specification.

Change the fourth paragraph to:

The type and any qualifications (flat, noperspective, centroid) of varying variables with the same name declared in both the vertex and fragment shaders must match, otherwise the link command will fail. Note that built-in varying variables, which have names starting with "gl_", can not be further qualified with flat, noperspective or centroid. The flat keyword cannot be used together with either the noperspective or centroid keywords to further qualify a single varying variable, otherwise a compile error will occur. When using the keywords centroid, flat or noperspective, it must immediately precede the varying keyword. When using both centroid and noperspective keywords, either one can be specified first. Only those varying variables used (i.e. read) in the fragment shader must be written to by the vertex shader; declaring superfluous varying variables in the vertex shader is permissible. Varying out variables, set per fragment, can not be further qualified with flat, noperspective or centroid.

Fragment shaders output values to the back-end of the OpenGL pipeline using either user-defined varying out variables or built-in variables, as described in section 7.2, unless the discard keyword is executed. If the back-end of the OpenGL pipeline consumes a user-defined varying out variable and an execution of a fragment shader does not write a value to that variable, then the value consumed is undefined. If the back-end of the OpenGL pipeline consumes a varying out variable and a fragment shader either writes values into less components of the variable, or if the variable is declared to have less components, than needed, the values of the missing component(s) are undefined. The OpenGL specification, section 3.x.x, describes API to route varying output variables to color buffers.

Add the following examples:

```
  noperspective varying float temperature;
  flat varying vec3 myColor;
  centroid varying vec2 myTexCoord;
  centroid noperspective varying vec2 myTexCoord;
  varying out ivec3 foo;
```

Change the third paragraph on p. 25 as follows:

The "varying" qualifier can be used only with the data types float, vec2, vec3, vec4, mat2, mat3, and mat4, int, ivec2, ivec3, ivec4, unsigned int, uvec2, uvec3, uvec4 or arrays of these. Structures cannot be varying. If the varying is declared as one of the integer or unsigned integer data type variants, then it has to also be qualified as being flat shaded, otherwise a compile error will occur.

The "varying out" qualifier can be used only with the data types float, vec2, vec3, vec4, int, ivec2, ivec3, ivec4, unsigned int, uvec2, uvec3 or uvec4. Structures or arrays cannot be declared as varying out.

Change section 5.1 "Operators"

Remove the "reserved" qualifications from the following operator precedence table entries:

```
  Precedence          Operator class
  ----------          -----------------------------------
      3               (tilde is reserved)
      4               (modulus reserved)
      6               bit-wise shift (reserved)
      9               bit-wise and (reserved)
     10               bit-wise exclusive or (reserved)
     11               bit-wise inclusive or (reserved)
     16               (modulus, shift, and bit-wise are reserved)
```

Change section 5.8 "Assignments"

Change the first bullet from:

   * The arithmetic assignments add into (+=)..

To:

   * The arithmetic assignments add into (+=), subtract from (-
     =), multiply into (*=), and divide into (/=) as well as the
     assignments modulus into (%=), left shift by (<<=), right
     shift by (>>=), and into (&=), inclusive or into (|=),
     exclusive or into (^=). The expression

Delete the last bullet in this paragraph.

Remove the second bullet in the section starting with: The assignments modulus into..

Change section 5.9 "Expressions"

Change the bullet: The operator modulus (%) is reserved for future use to:

* The arithmetic operator % that operates on signed or unsigned integer typed expressions (including vectors). The two operands must be of the same type, or one can be a signed or unsigned integer scalar and the other a signed or unsigned integer vector. If the second operand is zero, results are undefined. If one operand is scalar and the other is a vector, the scalar is applied component-wise to the vector, resulting in the same type as the vector. If both operands are non-negative, then the remainder is non-negative. Results are undefined if one, or both, operands are negative.

Change the last bullet: "Operators and (&), or (|), exclusive or (^), not (~), right-shift (>>), left shift (<<). These operators are reserved for future use." To the following bullets:

* The one's complement operator ~. The operand must be of type signed or unsigned integer (including vectors), and the result is the one's complement of its operand. If the operand is a vector, the operator is applied component-wise to the vector. If the operand is unsigned, the result is computed by subtracting the value from the largest unsigned integer value. If the operand is signed, the result is computed by converting the operand to an unsigned integer, applying ~, and converting back to a signed integer.

* The shift operators << and >>. For both operators, the operands must be of type signed or unsigned integer (including vectors). If the first operand is a scalar, the second operand has to be a scalar as well. The result is undefined if the right operand is negative, or greater than or equal to the number of bits in the left expression's type. The value of E1 << E2 is E1 (interpreted as a bit pattern) left-shifted by E2 bits. The value of E1 >> E2 is E1 right-shifted by E2 bit positions. If E1 is a signed integer, the right-shift will extend the sign bit. If E1 is an unsigned integer, the right-shift will zero-extend.

* The bitwise AND operator &. The operands must be of type signed or unsigned integer (including vectors). The two operands must be of the same type, or one can be a signed or unsigned integer scalar and the other a signed or unsigned integer vector. If one operand is a scalar and the other a vector, the scalar is applied component-wise to the vector, resulting in the same type as the vector. The result is the bitwise AND function of the operands.

* The bitwise exclusive OR operator ^. The operands must be of type signed or unsigned integer (including vectors). The two operands must be of the same type, or one can be a signed or unsigned integer scalar and the other a signed or unsigned integer vector. If one operand is a scalar and the other a vector, the scalar is applied component-wise to the vector, resulting in the same type as the vector. The result is the bitwise exclusive OR function of the operands.

* The bitwise inclusive OR operator |. The operands must be of type signed or unsigned integer (including vectors). The two operands must be of the same type, or one can be a signed or unsigned integer scalar and the other a signed or unsigned integer vector. If one operand is a scalar and the other a vector, the scalar is applied component-wise to the vector, resulting in the same type as the vector. The result is the bitwise inclusive OR function of the operands.

Change Section 7.1 "Vertex Shader Special Variables"

Add the following definition to the list of built-in variable definitions:

```
      int gl_VertexID   // read-only
      int gl_InstanceID // read-only
```

Add the following paragraph at the end of the section:

The variable gl_VertexID is available as a read-only variable from within vertex shaders and holds the integer index <i> implicitly passed to ArrayElement() to specify the vertex. The value of gl_VertexID is defined if and only if:

* the vertex comes from a vertex array command that specifies a complete primitive (e.g. DrawArrays, DrawElements),

* all enabled vertex arrays have non-zero buffer object bindings, and

* the vertex does not come from a display list, even if the display list was compiled using DrawArrays / DrawElements with data sourced from buffer objects.

The variable gl_InstanceID is availale as a read-only variable from within vertex shaders and holds holds the integer index of the current primitive in an instanced draw call (DrawArraysInstancedEXT, DrawElementsInstancedEXT). If the current primitive does not come from an instanced draw call, the value of gl_InstanceID is zero.

Change Section 7.2 "Fragment Shader Special Variables"

Change the 8th and 9th paragraphs on p. 43 as follows:

If a shader statically assigns a value to gl_FragColor, it may not assign a value to any element of gl_FragData nor to any user-defined varying output variable (section 4.3.6). If a shader statically writes a value to any element of gl_FragData, it may not assign a value to gl_FragColor nor to any user-defined varying output variable. That is, a shader may assign values to either gl_FragColor, gl_FragData, or any user-defined varying output variable, but not to a combination of the three options.

If a shader executes the discard keyword, the fragment is discarded, and the values of gl_FragDepth, gl_FragColor, gl_FragData and any user-defined varying output variables become irrelevant.

Add the following paragraph to the top of p. 44:

The variable gl_PrimitiveID is available as a read-only variable from within fragment shaders and holds the id of the currently processed primitive. Section 3.11, subsection "Shader Inputs" of the OpenGL 2.0 specification describes what value it holds based on the primitive type.

Add the following prototype to the list of built-in variables accessible from a fragment shader:

```
int gl_PrimitiveID;
```

Change Chapter 8, sixth paragraph on page 50:

Change the sentence:

When the built-in functions are specified below, where the input arguments (and corresponding output)can be float, vec2, vec3, or vec4, genType is used as the argument.

To:

When the built-in functions are specified below, where the input arguments (and corresponding output) can be float, vec2, vec3, or vec4, genType is used as the argument. Where the input arguments (and corresponding output) can be int, ivec2, ivec3 or ivec4, genIType is used as the argument. Where the input arguments (and corresponding output) can be unsigned int, uvec2, uvec3, or uvec4, genUType is used as the argument.

Add to section 8.3 "Common functions"

Add integer versions of the abs, sign, min, max and clamp functions, as follows:

Syntax:

```
genIType abs(genIType x)

genIType sign(genIType x)

genIType min(genIType x, genIType y)
genIType min(genIType x, int y)
genUType min(genUType x, genUType y)
genUType min(genUType x, unsigned int y)

genIType max(genIType x, genIType y)
genIType max(genIType x, int y)
genUType max(genUType x, genUType y)
genUType max(genUType x, unsigned int y)

genIType clamp(genIType x, genIType minval, genIType maxval)
genIType clamp(genIType x, int minval, int maxval)
genUType clamp(genUType x, genUType minval, genUType maxval)
genUType clamp(genUType x, unsigned int minval,
               unsigned int maxval)
```

Add the following new functions:

Syntax:

```
genType truncate(genType x)
```

Description:

Returns a value equal to the integer closest to x whose absolute value is not larger than the absolute value of x.

Syntax:

```
genType round(genType x)
```

Description:

Returns a value equal to the closest integer to x. If the fractional portion of the operand is 0.5, the nearest even integer is returned. For example, round (1.0) returns 1.0. round(-1.5) returns -2.0. round(3.5) and round (4.5) both return 4.0.

Add to section 8.6 "Vector Relational Functions"

Change the sentence:

Below, "bvec" is a placeholder for one of bvec2, bvec3, or bvec4, "ivec" is a placeholder for one of ivec2, ivec3, or ivec4, and "vec" is a placeholder for vec2, vec3, or vec4.

To:

Below, "bvec" is a placeholder for one of bvec2, bvec3, or bvec4, "ivec" is a placeholder for one of ivec2, ivec3, or ivec4, "uvec" is a placeholder for one of uvec2, uvec3 or uvec4 and "vec" is a placeholder for vec2, vec3, or vec4.

Add uvec versions of all but the any, all and not functions to the table in this section, as follows:

```
bvec lessThan(uvec x, uvec y)
bvec lessThanEqual(uvec x, uvec y)

bvec greaterThan(uvec x, uvec y)
bvec greaterThanEqual(uvec x, uvec y)

bvec equal(uvec x, uvec y)
bvec notEqual(uvec x, uvec y)
```

Add to section 8.7 "Texture Lookup Functions"

Remove the first sentence in the last paragraph:

"The built-ins suffixed with "Lod" are allowed only in a vertex shader.".

Add to this section:

Texture data can be stored by the GL as floating point, unsigned normalized integer, unsigned integer or signed integer data. This is determined by the type of the internal format of the texture. Texture lookups on unsigned normalized integer and floating point data return floating point values in the range [0, 1]. See also section 2.15.4.1 of the OpenGL specification.

Texture lookup functions are provided that can return their result as floating point, unsigned integer or signed integer, depending on the sampler type passed to the lookup function. Care must be taken to use the right sampler type for texture access. Table 8.xxx lists the supported combinations of sampler types and texture internal formats.

texture internal format	default (float) sampler	integer sampler	unsigned integer sampler
float	vec4	n/a	n/a
normalized	vec4	n/a	n/a
signed int	n/a	ivec4	n/a
unsigned int	n/a	n/a	uvec4

Table 8.xxx Valid combinations of the type of the internal format of a texture and the type of the sampler used to access the texture. Each cell in the table indicates the type of the return value of a texture lookup. N/a means this combination is not supported. A texture lookup using a n/a combination will return undefined values. The exceptions to this table are the "textureSize" lookup functions, which will return an integer or integer vector, regardless of the sampler type.

If a texture with a signed integer internal format is accessed, one of the signed integer sampler types must be used. If a texture with an unsigned integer internal format is accessed, one of the unsigned integer sampler types must be used. Otherwise, one of the default (float) sampler types must be used. If the types of a sampler and the corresponding texture internal format do not match, the result of a texture lookup is undefined.

If an integer sampler type is used, the result of a texture lookup is an ivec4. If an unsigned integer sampler type is used, the result of a texture lookup is a uvec4. If a default sampler type is used, the result of a texture lookup is a vec4, where each component is in the range [0, 1].

Integer and unsigned integer functions of all the texture lookup functions described in this section are also provided, except for the "shadow" versions, using function overloading. Their prototypes, however, are not listed separately. These overloaded functions use the integer or unsigned-integer versions of the sampler types and will return an ivec4 or an uvec4 respectively, except for the "textureSize" functions, which will always return an integer, or integer vector. Refer also to table 8.xxxx for valid combinations of texture internal formats and sampler types. For example, for the texture1D function, the complete set of prototypes is:

```
   vec4 texture1D(sampler1D sampler, float coord
                  [, float bias])
   ivec4 texture1D(isampler1D sampler, float coord
                   [, float bias])
   uvec4 texture1D(usampler1D sampler, float coord
                   [, float bias])
```

Add the following new texture lookup functions:

Syntax:

```
  vec4 texelFetch1D(sampler1D sampler, int coord, int lod)
  vec4 texelFetch2D(sampler2D sampler, ivec2 coord, int lod)
  vec4 texelFetch3D(sampler3D sampler, ivec3 coord, int lod)
  vec4 texelFetch2DRect(sampler2DRect sampler, ivec2 coord)
  vec4 texelFetch1DArray(sampler1DArray sampler, ivec2 coord, int lod)
  vec4 texelFetch2DArray(sampler2DArray sampler, ivec3 coord, int lod)
```

Description:

Use integer texture coordinate <coord> to lookup a single texel from the level-of-detail <lod> on the texture bound to <sampler> as described in section 2.15.4.1 of the OpenGL specification "Texel Fetches". For the "array" versions, the layer of the texture array to access is either coord.t or coord.p, depending on the use of the 1D or 2D texel fetch lookup, respectively. Note that texelFetch2DRect does not take a level-of-detail input.

Syntax:

```
  vec4 texelFetchBuffer(samplerBuffer sampler, int coord)
```

Description:

Use integer texture coordinate <coord> to lookup into the buffer texture bound to <sampler>.

Syntax:

```
  int textureSizeBuffer(samplerBuffer sampler)
  int textureSize1D(sampler1D sampler, int lod)
  ivec2 textureSize2D(sampler2D sampler, int lod)
  ivec3 textureSize3D(sampler3D sampler, int lod)
  ivec2 textureSizeCube(samplerCube sampler, int lod)
  ivec2 textureSize2DRect(sampler2DRect sampler, int lod)
  ivec2 textureSize1DArray(sampler1DArray sampler, int lod)
  ivec3 textureSize2DArray(sampler2DArray sampler, int lod)
```

Description:

Returns the dimensions, width, height, depth, and number of layers, of level <lod> for the texture bound to <sampler>, as described in section 2.15.4.1 of the OpenGL specification section "Texture Size Query". For the textureSize1DArray function, the first (".x") component of the returned vector is filled with the width of the texture image and the second component with the number of layers in the texture array. For the textureSize2DArray function, the first two components (".x" and ".y") of

```
    the returned vector are filled with the width and height of the texture
    image respectively. The third component (".z") is filled with the number
    of layers in the texture array.

    Syntax:

      vec4 texture1DArray(sampler1DArray sampler, vec2 coord
                          [, float bias])
      vec4 texture1DArrayLod(sampler1DArray sampler, vec2 coord,
                             float lod)

    Description:

    Use the first element (coord.s) of texture coordinate coord to do a
    texture lookup in the layer indicated by the second coordinate coord.t of
    the 1D texture array currently bound to sampler. The layer to access is
    computed by layer = max (0, min(d - 1, floor (coord.t + 0.5)) where 'd' is
    the depth of the texture array.

    Syntax:

      vec4 texture2DArray(sampler2DArray sampler, vec3 coord
                            [, float bias])
      vec4 texture2DArrayLod(sampler2DArray sampler, vec3 coord,
                               float lod)
    Description:

    Use the first two elements (coord.s, coord.t) of texture coordinate coord
    to do a texture lookup in the layer indicated by the third coordinate
    coord.p of the 2D texture array currently bound to sampler. The layer to
    access is computed by layer = max (0, min(d - 1, floor (coord.p + 0.5))
    where 'd' is the depth of the texture array.

    Syntax:

      vec4 shadow1DArray(sampler1DArrayShadow sampler, vec3 coord,
                         [float bias])
      vec4 shadow1DArrayLod(sampler1DArrayShadow sampler,
                            vec3 coord, float lod)
    Description:

    Use texture coordinate coord.s to do a depth comparison lookup on an array
    layer of the depth texture bound to sampler, as described in section
    3.8.14 of version 2.0 of the OpenGL specification. The layer to access is
    indicated by the second coordinate coord.t and is computed by layer = max
    (0, min(d - 1, floor (coord.t + 0.5)) where 'd' is the depth of the
    texture array. The third component of coord (coord.p) is used as the R
    value. The texture bound to sampler must be a depth texture, or results
    are undefined.

    Syntax:

      vec4 shadow2DArray(sampler2DArrayShadow sampler, vec4 coord)
    Description:

    Use texture coordinate (coord.s, coord.t) to do a depth comparison lookup
    on an array layer of the depth texture bound to sampler, as described in
    section 3.8.14 of version 2.0 of the OpenGL specification. The layer to
    access is indicated by the third coordinate coord.p and is computed by
    layer = max (0, min(d - 1, floor (coord.p + 0.5)) where 'd' is the depth
    of the texture array. The fourth component of coord (coord.q) is used as
    the R value. The texture bound to sampler must be a depth texture, or
    results are undefined.

    Syntax:

        vec4 shadowCube(samplerCubeShadow sampler, vec4 coord)

    Description:

    Use texture coordinate (coord.s, coord.t, coord.p) to do a depth
    comparison lookup on the depth cubemap bound to sampler, as described in
    section 3.8.14. The direction of the vector (coord.s, coord.t, coord.p) is
    used to select which face to do a two-dimensional texture lookup in, as
    described in section 3.8.6 of the OpenGL 2.0 specification. The fourth
    component of coord (coord.q) is used as the R value. The texture bound to
    sampler must be a depth cubemap, otherwise results are undefined.

    Syntax:

      vec4 texture1DGrad(sampler1D sampler, float coord,
                         float ddx, float ddy);
      vec4 texture1DProjGrad(sampler1D sampler, vec2 coord,
                             float ddx, float ddy);
      vec4 texture1DProjGrad(sampler1D sampler, vec4 coord,
                             float ddx, float ddy);
      vec4 texture1DArrayGrad(sampler1DArray sampler, vec2 coord,
                              float ddx, float ddy);

      vec4 texture2DGrad(sampler2D sampler, vec2 coord,
                         vec2 ddx, vec2 ddy);
      vec4 texture2DProjGrad(sampler2D sampler, vec3 coord,
                             vec2 ddx, vec2 ddy);
      vec4 texture2DProjGrad(sampler2D sampler, vec4 coord,
                             vec2 ddx, vec2 ddy);
      vec4 texture2DArrayGrad(sampler2DArray sampler, vec3 coord,
                              vec2 ddx, vec2 ddy);

      vec4 texture3DGrad(sampler3D sampler, vec3 coord,
                         vec3 ddx, vec3 ddy);
      vec4 texture3DProjGrad(sampler3D sampler, vec4 coord,
                             vec3 ddx, vec3 ddy);

      vec4 textureCubeGrad(samplerCube sampler, vec3 coord,
                           vec3 ddx, vec3 ddy);
      vec4 shadow1DGrad(sampler1DShadow sampler, vec3 coord,
                         float ddx, float ddy);
      vec4 shadow1DProjGrad(sampler1DShadow sampler, vec4 coord,
                             float ddx, float ddy);
      vec4 shadow1DArrayGrad(sampler1DArrayShadow sampler, vec3 coord,
                              float ddx, float ddy);

      vec4 shadow2DGrad(sampler2DShadow sampler, vec3 coord,
                         vec2 ddx, vec2 ddy);
      vec4 shadow2DProjGrad(sampler2DShadow sampler, vec4 coord,
                             vec2 ddx, vec2 ddy);
      vec4 shadow2DArrayGrad(sampler2DArrayShadow sampler, vec4 coord,
                              vec2 ddx, vec2 ddy);

      vec4 texture2DRectGrad(sampler2DRect sampler, vec2 coord,
                              vec2 ddx, vec2 ddy);
      vec4 texture2DRectProjGrad(sampler2DRect sampler, vec3 coord,
                                  vec2 ddx, vec2 ddy);
      vec4 texture2DRectProjGrad(sampler2DRect sampler, vec4 coord,
                                  vec2 ddx, vec2 ddy);

      vec4 shadow2DRectGrad(sampler2DRectShadow sampler, vec3 coord,
                             vec2 ddx, vec2 ddy);
      vec4 shadow2DRectProjGrad(sampler2DRectShadow sampler, vec4 coord,
                                 vec2 ddx, vec2 ddy);

      vec4 shadowCubeGrad(samplerCubeShadow sampler, vec4 coord,
                           vec3 ddx, vec3 ddy);
```

Description:

The "Grad" functions map the partial derivatives ddx and ddy to ds/dx, dt/dx, dr/dx, and ds/dy, dt/dy, dr/dy respectively and use texture coordinate "coord" to do a texture lookup as described for their non "Grad" counterparts. The derivatives ddx and ddy are used as the explicit derivate of "coord" with respect to window x and window y respectively and are used to compute lambda_base(x,y) as in equation 3.18 in the OpenGL 2.0 specification. For the "Proj" versions, it is assumed that the partial derivatives ddx and ddy are already projected. I.e. the GL assumes that ddx and ddy represent d(s/q)/dx, d(t/q)/dx, d(r/q)/dx and d(s/q)/dy, d(t/q)/dy, d(r/q)/dy respectively. For the "Cube" versions, the partial derivatives ddx and ddy are assumed to be in the coordinate system used before texture coordinates are projected onto the appropriate cube face. The partial derivatives of the post-projection texture coordinates, which are used for level-of-detail and anisotropic filtering calculations, are derived from coord, ddx and ddy in an implementation-dependent manner.

NOTE: Except for the "array" and shadowCubeGrad() functions, these functions are taken from the ARB_shader_texture_lod spec and are functionally equivalent.

```
    Syntax:

      vec4 texture1DOffset(sampler1D sampler, float coord,
                           int offset [,float bias])
      vec4 texture1DProjOffset(sampler1D sampler, vec2 coord,
                               int offset [,float bias])
      vec4 texture1DProjOffset(sampler1D sampler, vec4 coord,
                               int offset [,float bias])
      vec4 texture1DLodOffset(sampler1D sampler, float coord,
                              float lod, int offset)
      vec4 texture1DProjLodOffset(sampler1D sampler, vec2 coord,
                                  float lod, int offset)
      vec4 texture1DProjLodOffset(sampler1D sampler, vec4 coord,
                                  float lod, int offset)

      vec4 texture2DOffset(sampler2D sampler, vec2 coord,
                           ivec2 offset [,float bias])
      vec4 texture2DProjOffset(sampler2D sampler, vec3 coord,
                               ivec2 offset [,float bias])

    vec4 texture2DProjGradOffset(sampler2D sampler, vec3 coord,
                                 vec2 ddx, vec2 ddy, ivec2 offset);
    vec4 texture2DProjGradOffset(sampler2D sampler, vec4 coord,
                                 vec2 ddx, vec2 ddy, ivec2 offset);
    vec4 texture2DArrayGradOffset(sampler2DArray sampler, vec3 coord,
                                  vec2 ddx, vec2 ddy, ivec2 offset);

    vec4 texture3DGradOffset(sampler3D sampler, vec3 coord,
                             vec3 ddx, vec3 ddy, ivec3 offset);
    vec4 texture3DProjGradOffset(sampler3D sampler, vec4 coord,
                                 vec3 ddx, vec3 ddy, ivec3 offset);

    vec4 shadow1DGradOffset(sampler1DShadow sampler, vec3 coord,
                            float ddx, float ddy, int offset);
    vec4 shadow1DProjGradOffset(sampler1DShadow sampler,
                                vec4 coord, float ddx, float ddy,
                                int offset);
    vec4 shadow1DArrayGradOffset(sampler1DArrayShadow sampler,
                                 vec3 coord, float ddx, float ddy,
                                 int offset);

    vec4 shadow2DGradOffset(sampler2DShadow sampler, vec3 coord,
                            vec2 ddx, vec2 ddy, ivec2 offset);
    vec4 shadow2DProjGradOffset(sampler2DShadow sampler, vec4 coord,
                                vec2 ddx, vec2 ddy, ivec2 offset);
    vec4 shadow2DArrayGradOffset(sampler2DArrayShadow sampler,
                                 vec4 coord, vec2 ddx, vec2 ddy,
                                 ivec2 offset);

    vec4 texture2DRectGradOffset(sampler2DRect sampler, vec2 coord,
                                 vec2 ddx, vec2 ddy, ivec2 offset);
    vec4 texture2DRectProjGradOffset(sampler2DRect sampler, vec3 coord,
                                     vec2 ddx, vec2 ddy, ivec2 offset);
    vec4 texture2DRectProjGradOffset(sampler2DRect sampler, vec4 coord,
                                     vec2 ddx, vec2 ddy, ivec2 offset);

    vec4 shadow2DRectGradOffset(sampler2DRectShadow sampler,
                                vec3 coord, vec2 ddx, vec2 ddy,
                                ivec2 offset);
    vec4 shadow2DRectProjGradOffset(sampler2DRectShadow sampler,
                                    vec4 coord, vec2 ddx, vec2 ddy,
                                    ivec2 offset);
```

Description:

The "offset" version of each function provides an extra parameter <offset> which is added to the (u,v,w) texel coordinates before looking up each texel. The offset value must be a constant expression. A limited range of offset values are supported; the minimum and maximum offset values are implementation-dependent and given by MIN_PROGRAM_TEXEL_OFFSET_EXT and MAX_PROGRAM_TEXEL_OFFSET_EXT, respectively. Note that <offset> does not apply to the layer coordinate for texture arrays. This is explained in detail in section 3.8.7 of the OpenGL Specification. Note that texel offsets are also not supported for cubemaps or buffer textures.

Add to section 9 "Grammar"

```

Issues

1. *Should we support shorts in GLSL?*

   DISCUSSION:

   RESOLUTION: UNRESOLVED

2. *Do bitwise shifts, AND, exclusive OR and inclusive OR support all combinations of scalars and vectors for each operand?*

   DISCUSSION: It seems sense to support scalar OP scalar, vector OP scalar and vector OP vector. But what about scalar OP vector? Should the scalar be promoted to a vector first?

   RESOLUTION: RESOLVED. Yes, this should work essentially as the '+' operator. The scalar is applied to each component of the vector.

3. *Which built-in functions should also operate on integers?*

   DISCUSSION: There are several that don't make sense to define to operate on integers at all, but the following can be debated: pow, sqrt, dot (and the functions that use dot), cross.

   RESOLUTION: RESOLVED. Integer versions of the abs, sign, min, max and clamp functions are defined. Note that the modulus operator % has been defined for integer operands.

4. *Do we need to support integer matrices?*

   DISCUSSION:

   RESOLUTION: RESOLVED No, not at the moment.

5. Which texture array lookup functions do we need to support?

DISCUSSION: We don't want to support lookup functions that need more than four components passed as parameters. Components can be used for texture coordinates, layer selection, 'R' depth compare and the 'q' coordinate for projection. However, texture projection might be relatively easy to support through code-generation, thus we might be able to support functions that need five components, as long as one of them is 'q' for projective texturing. Specifically, should we support:

```
vec4 texture2DArrayProjLod(sampler2DArray sampler, vec4 coord,
                           float lod)
vec4 shadow1DArray(sampler1DArrayShadow sampler, vec3 coord,
                 [float bias])
vec4 shadow1DArrayProj(sampler1DArrayShadow sampler, vec4 coord,
                       [float bias])
vec4 shadow1DArrayLod(sampler1DArrayShadow sampler, vec3 coord,
                      float lod)
vec4 shadow1DArrayProjLod(sampler1DArrayShadow sampler,
                          vec4 coord, float lod)
vec4 shadow2DArray(sampler2DArrayShadow sampler, vec4 coord)
vec4 shadow2DArrayProj(sampler2DArrayShadow sampler, vec4 coord,
                       float refValue)
```

RESOLUTION: RESOLVED, We'll support all but the "Proj" versions. The assembly spec (NV_gpu_program4) doesn't support the equivalent functionality, either.

6. How do we handle conversions between integer and unsigned integers?

DISCUSSION: Do we allow automatic type conversions between signed and unsigned integers?

RESOLUTION: RESOLVED. We will not add this until GLSL version 1.20 has been defined, and the implicit conversion rules have been established there. If we do this, we would likely only support implicit conversion from int to unsigned int, just like C does.

7. Should varying modifiers (flat, noperspective) apply to built-in varying variables also?

DISCUSSION: There is API to control flat vs smooth shading for colors through glShadeModel(). There is also API to hint if colors should be interpolated perspective correct, or not, through glHint(). These API commands apply to the built-in color varying variables (gl_FrontColor etc). If the varying modifiers in a shader also apply to the color built-ins, which has precedence?

RESOLUTION: RESOLVED. It is simplest and cleanest to only allow the varying modifiers to apply to user-defined varying variables. The behavior of the built-in color varying variables can still be controlled through the API.

8. How should perspective-incorrect interpolation (linear in screen space) and clipping interact?

RESOLVED: Primitives with attributes specified to be perspective-incorrect should be clipped so that the vertices introduced by clipping should have attribute values consistent with the interpolation mode. We do not want to have large color shifts introduced by clipping a perspective-incorrect attribute. For example, a primitive that approaches, but doesn't cross, a frustum clip plane should look pretty much identical to a similar primitive that just barely crosses the clip plane.

Clipping perspective-incorrect interpolants that cross the W==0 plane is very challenging. The attribute clipping equation provided in the spec effectively projects all the original vertices to screen space while ignoring the X and Y frustum clip plane. As W approaches zero, the projected X/Y window coordinates become extremely large. When clipping an edge with one vertex inside the frustum and the other out near infinity (after projection, due to W approaching zero), the interpolated attribute for the entire visible portion of the edge should almost exactly match the attribute value of the visible vertex.

If an outlying vertex approaches and then goes past W==0, it can be said to go "to infinity and beyond" in screen space. The correct answer for screen-linear interpolation is no longer obvious, at least to the author of this specification. Rather than trying to figure out what the "right" answer is or if one even exists, the results of clipping such edges is specified as undefined.

9. Do we need to support a non-MRT fragment shader writing to (unsigned) integer outputs?

DISCUSSION: Fragment shaders with only one fragment output are considered non-MRT shaders. This means that the output of the shader gets smeared across all color buffers attached to the framebuffer. Fragment shaders with multiple fragment outputs are MRT shaders. Each output is directed to a color buffer using the DrawBuffers API (for gl_FragData) and a combination of the BindFragDataLocationEXT and DrawBuffers API (for varying out variables). Before this extension, a non-MRT shader would write to gl_Color only. A shader writing to gl_FragData[] is a MRT shader. With the addition of varying out variables in this extension, any shader writing to a variable out variable is a MRT shader. It is not possible to construct a non-MRT shader writing to varying out variables. Varying out variables can be declared to be of type integer or unsigned integer. In order to support a non-MRT shader that can write to (unsigned) integer outputs, we could define two new built-in variables:

```
  ivec4 gl_FragColorInt;
  uvec4 gl_FragColorUInt;
```

Or we could add a special rule stating that if the program object writes to exactly one varying out variable, it is considered to be non-MRT.

RESOLUTION: NO. We don't care enough to support this.

10. *Is section 2.14.8, "Color and Associated Data Clipping" in the core specification still correct?*

    DISCUSSION: This section is in need of some updating, now that varying variables can be interpolated without perspective correction. Some (not so precise) language has been added in the spec body, suggesting that the interpolation needs to be performed in such a way as to produce results that vary linearly in screen space. However, we could define the exact interpolation method required to achieve this. A suggested updated paragraph follows, but we'll leave updating section 2.14.8 to a future edit of the core specification, not this extension.

    Replace Section 2.14.8, and rename it to "Vertex Attribute Clipping"

    After lighting, clamping or masking and possible flatshading, vertex attributes, including colors, texture and fog coordinates, shader varying variables, and point sizes computed on a per vertex basis, are clipped. Those attributes associated with a vertex that lies within the clip volume are unaffected by clipping. If a primitive is clipped, however, the attributes assigned to vertices produced by clipping are produced by interpolating attributes along the clipped edge.

    Let the attributes assigned to the two vertices P_1 and P_2 of an unclipped edge be a_1 and a_2. The value of t (section 2.12) for a clipped point P is used to obtain the attribute associated with P as

    ```
    a = t * a_1 + (1-t) * a_2
    ```

    unless the attribute is specified to be interpolated without perspective correction in a shader (using the noperspective keyword). In that case, the attribute associated with P is

    ```
    a = t' * a_1 + (1-t') * a_2
    ```

    where

    ```
    t' = (t * w_1) / (t * w_1 + (1-t) * w_2)
    ```

    and w_1 and w_2 are the w clip coordinates of P_1 and P_2, respectively. If w_1 or w_2 is either zero or negative, the value of the associated attribute is undefined.

    For a color index color, multiplying a color by a scalar means multiplying the index by the scalar. For a vector attribute, it means multiplying each vector component by the scalar. Polygon clipping may create a clipped vertex along an edge of the clip volume's boundary. This situation is handled by noting that polygon clipping proceeds by clipping against one plane of the clip volume's boundary at a time. Attribute clipping is done in the same way, so that clipped points always occur at the intersection of polygon edges (possibly already clipped) with the clip volume's boundary.

11. *When and where in the texture filtering process are texel offsets applied?*

    DISCUSSION: Texel offsets are applied to the (u,v,w) coordinates of the base level of the texture if the texture filter mode does not indicate mipmapping. Otherwise, texel offsets are applied to the (u,v,w) coordinates of the mipmap level 'd', as found by equation 3.27 or to mipmap levels 'd1' and 'd2' as found by equation 3.28 in the OpenGL 2.0 specification. In other words, texel offsets are applied to the (u,v,w) coordinate of whatever mipmap level is accessed.

12. *Why is writing to the built-in output variable "gl_Position" in a vertex shader now optional?*

    DISCUSSION: Before this specification, writing to gl_Position in a vertex shader was mandatory. The GL pipeline required a vertex position to be written in order to produce well-defined output. This is still the case if the GL pipeline indeed needs a vertex position. However, with fourth-generation programmable hardware there are now cases where the GL pipeline no longer requires a vertex position in order to produce well-defined results. If a geometry shader is present, the vertex shader does not need to write to gl_Position anymore. Instead, the geometry shader can compute a vertex position and write to its gl_Position output. In case of transform-feedback, where the output of a vertex or geometry shader is streamed to one or more buffer objects, perfectly valid results can be obtained without either the vertex shader nor geometry shader writing to gl_Position. The transform-feedback specification adds a new enable to discard primitives right before rasterization, making it potentially unnecessary to write to gl_Position.

Revision History

Rev.	Date	Author	Changes
12	02/04/08	pbrown	Fix errors in texture wrap mode handling. Added a missing clamp to avoid sampling border in REPEAT mode. Fixed incorrectly specified weights for LINEAR filtering.
11	05/08/07	pbrown	Add VertexAttribIPointerEXT to the list of commands that can't go in display lists.
10	01/23/07	pbrown	Fix prototypes for a variety of functions that were specified with an incorrect sampler type.
9	12/15/06	pbrown	Documented that the '#extension' token for this extension should begin with "GL_", as apparently called for per convention.
8	--		Pre-release revisions.

Name

    EXT_multi_draw_arrays

Name Strings

    GL_EXT_multi_draw_arrays

Version

    $Date: 1998/04/03 04:35:50 $ $Revision: 1.1 $

Number

    148

Dependencies

    OpenGL 1.1 is required. The language is written against the OpenGL 1.2
    specification.

Overview

    These functions behave identically to the standard OpenGL 1.1 functions
    glDrawArrays() and glDrawElements() except they handle multiple lists of
    vertices in one call. Their main purpose is to allow one function call
    to render more than one primitive such as triangle strip, triangle fan,
    etc.

New Procedures and Functions

```
    void glMultiDrawArraysEXT( GLenum mode,
                               GLint *first,
                               GLsizei *count,
                               GLsizei primcount)
    Parameters
    ----------
        mode            Specifies what kind of primitives to
                        render. Symbolic constants GL_POINTS,
                        GL_LINE_STRIP, GL_LINE_LOOP, GL_LINES,
                        GL_TRIANGLE_STRIP, GL_TRIANGLE_FAN,
                        GL_TRIANGLES, GL_QUAD_STRIP, GL_QUADS,
                        and GL_POLYGON are accepted.

        first           Points to an array of starting indices in
                        the enabled arrays.

        count           Points to an array of the number of indices
                        to be rendered.

        primcount       Specifies the size of first and count
    void glMultiDrawElementsEXT( GLenum mode,
                                 GLsizei *count,
                                 GLenum type,
                                 const GLvoid **indices,
                                 GLsizei primcount)

    Parameters
    ----------
        mode            Specifies what kind of primitives to render.
                        Symbolic constants GL_POINTS, GL_LINE_STRIP,
                        GL_LINE_LOOP, GL_LINES, GL_TRIANGLE_STRIP,
                        GL_TRIANGLE_FAN, GL_TRIANGLES, GL_QUAD_STRIP,
                        GL_QUADS, and GL_POLYGON are accepted.

        count           Points to and array of the element counts

        type            Specifies the type of the values in indices.
                        Must be  one  of GL_UNSIGNED_BYTE,
                        GL_UNSIGNED_SHORT, or GL_UNSIGNED_INT.

        indices         Specifies a  pointer to the location where
                        the indices are stored.

        primcount       Specifies the size of the count array
```

    None

Additions to Chapter 2 of the 1.2 Specification (OpenGL Operation)

    Section 2.8 Vertex Arrays:

    The command

```
        void glMultiDrawArraysEXT( GLenum mode,
                                   GLint* first,
                                   GLsizei *count,
                                   GLsizei primcount)
```

    Behaves identically to DrawArrays except that a list of arrays is
    specified instead. The number of lists is specified in the primcount
    parameter. It has the same effect as:

```
        for(i=0; i<primcount; i++) {
           if (*(count+i)>0) DrawArrays(mode, *(first+i), *(count+i));
        }
```

The command

```
    void glMultiDrawElementsEXT( GLenum mode,
                                 GLsizei *count,
                                 GLenum type,
                                 const GLvoid **indices,
                                 GLsizei primcount)
```

Behaves identically to DrawElements except that a list of arrays is specified instead. The number of lists is specified in the primcount parameter. It has the same effect as:

```
    for(i=0; i<primcount; i++) {
        if (*(count+i)>0) DrawElements(mode, *(count+i), type,
                                       *(indices+i));
    }
```

Status

    Shipping for GeForce 8 Series (November 2006)

Version

    Date: November 6, 2006
    Revision: 0.4

Number

    328

Dependencies

    OpenGL 1.1 required

    ARB_color_buffer_float affects this extension.

    EXT_texture_shared_exponent trivially affects this extension.

    EXT_framebuffer_object affects this extension.

    WGL_ARB_pixel_format is required for use with WGL.

    WGL_ARB_pbuffer affects WGL pbuffer support for this extension.

    GLX 1.3 is required for use with GLX.

    This extension is written against the OpenGL 2.0 (September 7,
    2004) specification.

Overview

    This extension adds a new 3-component floating-point texture format
    that fits within a single 32-bit word. This format stores 5 bits
    of biased exponent per component in the same manner as 16-bit
    floating-point formats, but rather than 10 mantissa bits, the red,
    green, and blue components have 6, 6, and 5 bits respectively.
    Each mantissa is assumed to have an implied leading one except in the
    denorm exponent case. There is no sign bit so only non-negative
    values can be represented. Positive infinity, positive denorms,

    and positive NaN values are representable. The value of the fourth
    component returned by a texture fetch is always 1.0.

    This extension also provides support for rendering into an unsigned
    floating-point rendering format with the assumption that the texture
    format described above could also be advertised as an unsigned
    floating-point format for rendering.

    The extension also provides a pixel external format for specifying
    packed float values directly.

New Procedures and Functions

    None

New Tokens

```
    Accepted by the <internalformat> parameter of TexImage1D,
    TexImage2D, TexImage3D, CopyTexImage1D, CopyTexImage2D, and
    RenderbufferStorageEXT:

        R11F_G11F_B10F_EXT                          0x8C3A

    Accepted by the <type> parameter of DrawPixels, ReadPixels,
    TexImage1D, TexImage2D, GetTexImage, TexImage3D, TexSubImage1D,
    TexSubImage2D, TexSubImage3D, GetHistogram, GetMinmax,
    ConvolutionFilter1D, ConvolutionFilter2D, ConvolutionFilter3D,
    GetConvolutionFilter, SeparableFilter2D, GetSeparableFilter,
    ColorTable, ColorSubTable, and GetColorTable:

        UNSIGNED_INT_10F_11F_11F_REV_EXT            0x8C3B

    Accepted by the <pname> parameters of GetIntegerv, GetFloatv, and
    GetDoublev:

        RGBA_SIGNED_COMPONENTS_EXT                  0x8C3C

    Accepted as a value in the <piAttribIList> and <pfAttribFList>
    parameter arrays of wglChoosePixelFormatARB, and returned in the
    <piValues> parameter array of wglGetPixelFormatAttribivARB, and the
    <pfValues> parameter array of wglGetPixelFormatAttribfvARB:

        WGL_TYPE_RGBA_UNSIGNED_FLOAT_EXT            0x20A8

    Accepted as values of the <render_type> arguments in the
    glXCreateNewContext and glXCreateContext functions

        GLX_RGBA_UNSIGNED_FLOAT_TYPE_EXT            0x20B1

    Returned by glXGetFBConfigAttrib (when <attribute> is set to
    GLX_RENDER_TYPE) and accepted by the <attrib_list> parameter of
    glXChooseFBConfig (following the GLX_RENDER_TYPE token):

        GLX_RGBA_UNSIGNED_FLOAT_BIT_EXT              0x00000008
```

Additions to Chapter 2 of the 2.0 Specification (OpenGL Operation)

-- Add two new sections after Section 2.1.2, (page 6):

2.1.A Unsigned 11-Bit Floating-Point Numbers

An unsigned 11-bit floating-point number has no sign bit, a 5-bit exponent (E), and a 6-bit mantissa (M). The value of an unsigned 11-bit floating-point number (represented as an 11-bit unsigned integer N) is determined by the following:

```
    0.0,                        if E == 0 and M == 0,
    2^-14 * (M / 64),           if E == 0 and M != 0,
    2^(E-15) * (1 + M/64),      if 0 < E < 31,
    INF,                        if E == 31 and M == 0, or
    NaN,                        if E == 31 and M != 0,
```

where

```
    E = floor(N / 64), and
    M = N mod 64.
```

Implementations are also allowed to use any of the following alternative encodings:

```
    0.0,                        if E == 0 and M != 0
    2^(E-15) * (1 + M/64)       if E == 31 and M == 0
    2^(E-15) * (1 + M/64)       if E == 31 and M != 0
```

When a floating-point value is converted to an unsigned 11-bit floating-point representation, finite values are rounded to the closet representable finite value. While less accurate, implementations are allowed to always round in the direction of zero. This means negative values are converted to zero. Likewise, finite positive values greater than 65024 (the maximum finite representable unsigned 11-bit floating-point value) are converted to 65024. Additionally: negative infinity is converted to zero; positive infinity is converted to positive infinity; and both positive and negative NaN are converted to positive NaN.

Any representable unsigned 11-bit floating-point value is legal as input to a GL command that accepts 11-bit floating-point data. The result of providing a value that is not a floating-point number (such as infinity or NaN) to such a command is unspecified, but must not lead to GL interruption or termination. Providing a denormalized number or negative zero to GL must yield predictable results.

2.1.B Unsigned 10-Bit Floating-Point Numbers

An unsigned 10-bit floating-point number has no sign bit, a 5-bit exponent (E), and a 5-bit mantissa (M). The value of an unsigned 10-bit floating-point number (represented as an 10-bit unsigned integer N) is determined by the following:

```
    0.0,                      if E == 0 and M == 0,
    2^-14 * (M / 32),         if E == 0 and M != 0,
    2^(E-15) * (1 + M/32),    if 0 < E < 31,
    INF,                      if E == 31 and M == 0, or
    NaN,                      if E == 31 and M != 0,
```

where

```
    E = floor(N / 32), and
    M = N mod 32.
```

When a floating-point value is converted to an unsigned 10-bit floating-point representation, finite values are rounded to the closet representable finite value. While less accurate, implementations are allowed to always round in the direction of zero. This means negative values are converted to zero. Likewise, finite positive values greater than 64512 (the maximum finite representable unsigned 10-bit floating-point value) are converted to 64512. Additionally: negative infinity is converted to zero; positive infinity is converted to positive infinity; and both positive and negative NaN are converted to positive NaN.

Any representable unsigned 10-bit floating-point value is legal as input to a GL command that accepts 10-bit floating-point data. The result of providing a value that is not a floating-point number (such as infinity or NaN) to such a command is unspecified, but must not lead to GL interruption or termination. Providing a denormalized number or negative zero to GL must yield predictable results.

Additions to Chapter 3 of the 2.0 Specification (Rasterization)

-- Section 3.6.4, Rasterization of Pixel Rectangles

Add a new row to Table 3.5 (page 128):

type Parameter Token Name	Corresponding GL Data Type	Special Interpretation
UNSIGNED_INT_10F_11F_11F_REV_EXT	uint	yes

Add a new row to table 3.8: Packed pixel formats (page 132):

type Parameter Token Name	GL Data Type	Number of Components	Matching Pixel Formats
UNSIGNED_INT_10F_11F_11F_REV_EXT	uint	3	RGB

    Add a new entry to table 3.11: UNSIGNED_INT formats (page 134):

        UNSIGNED_INT_10F_11F_11F_REV_EXT:

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
  +----------------------------+-------------------------------+---------------------------------+
  |          3rd               |            2nd                |             1st                 |
  +----------------------------+-------------------------------+---------------------------------+
```

    Add to the end of the 2nd paragraph starting "Pixels are draw using":

    "If type is UNSIGNED_INT_10F_11F_11F_REV_EXT and format is not RGB
    then the error INVALID_ENUM occurs."

    Add UNSIGNED_INT_10F_11F_11F_REV_EXT to the list of packed formats
    in the 10th paragraph after the "Packing" subsection (page 130).

    Add before the 3rd paragraph (page 135, starting "Calling DrawPixels
    with a type of BITMAP...") from the end of the "Packing" subsection:

    "Calling DrawPixels with a type of UNSIGNED_INT_10F_11F_11F_REV_EXT
    and format of RGB is a special case in which the data are a series
    of GL uint values. Each uint value specifies 3 packed components
    as shown in table 3.11. The 1st, 2nd, and 3rd components are
    called f_red (11 bits), f_green (11 bits), and f_blue (10 bits)
    respectively.

    f_red and f_green are treated as unsigned 11-bit floating-point values
    and converted to floating-point red and green components respectively
    as described in section 2.1.A. f_blue is treated as an unsigned
    10-bit floating-point value and converted to a floating-point blue
    component as described in section 2.1.B."

-- Section 3.8.1, Texture Image Specification:

    "Alternatively if the internalformat is R11F_G11F_B10F_EXT, the red,
    green, and blue bits are converted to unsigned 11-bit, unsigned
    11-bit, and unsigned 10-bit floating-point values as described
    in sections 2.1.A and 2.1.B. These encoded values can be later
    decoded back to floating-point values due to texture image sampling
    or querying."

    Add a new row to Table 3.16 (page 154).

Sized Internal Format	Base Internal Format	R bits	G bits	B bits	A bits	L bits	I bits	D bits
R11F_G11F_B10F_EXT	RGB	11	11	10				

Additions to Chapter 4 of the 2.0 Specification (Per-Fragment Operations and the Frame Buffer)

-- Modify Chapter 4 Introduction, (page 198)

Modify first sentence of third paragraph (page 198):

"Color buffers consist of either signed or unsigned integer color indices, R, G, B and optionally A signed or unsigned integer values, or R, G, B, and optionally A signed or unsigned floating-point values."

-- Section 4.3.2, Reading Pixels

Add a row to table 4.7 (page 224);

type Parameter	GL Data Type	Component Conversion Formula
UNSIGNED_INT_10F_11F_11F_REV_EXT	uint	special

Replace second paragraph of "Final Conversion" (page 222) to read:

For an RGBA color, if <type> is not one of FLOAT, UNSIGNED_INT_5_9_9_9_REV_EXT, or UNSIGNED_INT_10F_11F_11F_REV_EXT, or if the CLAMP_READ_COLOR_ARB is TRUE, or CLAMP_READ_COLOR_ARB is FIXED_ONLY_ARB and the selected color (or texture) buffer is a fixed-point buffer, each component is first clamped to [0,1]. Then the appropriate conversion formula from table 4.7 is applied the component."

Add a paragraph after the second paragraph of "Final Conversion" (page 222):

"In the special case when calling ReadPixels with a type of UNSIGNED_INT_10F_11F_11F_REV_EXT and format of RGB, the conversion is done as follows: The returned data are packed into a series of GL uint values. The red, green, and blue components are converted to unsigned 11-bit floating-point, unsigned 11-bit floating-point, and unsigned 10-bit floating point as described in section 2.1.A and 2.1.B. The resulting red 11 bits, green 11 bits, and blue 10 bits are then packed as the 1st, 2nd, and 3rd components of the UNSIGNED_INT_10F_11F_11F_REV_EXT format as shown in table 3.11."

Additions to Chapter 5 of the 2.0 Specification (Special Functions)

None

Additions to Chapter 6 of the 2.0 Specification (State and State Requests)

None

Additions to the OpenGL Shading Language specification

None

Additions to Chapter 3 of the GLX 1.3 Specification (Functions and Errors)

Replace Section 3.3.3 (p.12) Paragraph 4 to:

The attribute GLX_RENDER_TYPE has as its value a mask indicating what type of GLXContext a drawable created with the corresponding GLXFBConfig can be bound to. The following bit settings are supported: GLX_RGBA_BIT, GLX_RGBA_FLOAT_BIT, GLX_RGBA_UNSIGNED_FLOAT_BIT, GLX_COLOR_INDEX_BIT. If combinations of bits are set in the mask then drawables created with the GLXFBConfig can be bound to those corresponding types of rendering contexts.

Add to Section 3.3.3 (p.15) after first paragraph:

Note that unsigned floating point rendering is only supported for GLXPbuffer drawables. The GLX_DRAWABLE_TYPE attribute of the GLXFBConfig must have the GLX_PBUFFER_BIT bit set and the GLX_RENDER_TYPE attribute must have the GLX_RGBA_UNSIGNED_FLOAT_BIT set. Unsigned floating point rendering assumes the framebuffer format has no sign bits so all component values are non-negative. In contrast, conventional floating point rendering assumes signed components.

Modify Section 3.3.7 (p.25 Rendering Contexts) remove period at end of second paragraph and replace with:

; if render_type is set to GLX_RGBA_UNSIGNED_FLOAT_TYPE then a context that supports unsigned floating point RGBA rendering is created.

GLX Protocol

None.

Additions to the WGL Specification

Modify the values accepted by WGL_PIXEL_TYPE_ARB to:

WGL_PIXEL_TYPE_ARB
The type of pixel data. This can be set to WGL_TYPE_RGBA_ARB, WGL_TYPE_RGBA_FLOAT_ARB, WGL_TYPE_RGBA_UNSIGNED_FLOAT_EXT, or WGL_TYPE_COLORINDEX_ARB.

Add this explanation of unsigned floating point rendering:

"Unsigned floating point rendering assumes the framebuffer format has no sign bits so all component values are non-negative. In contrast, conventional floating point rendering assumes signed components."

Dependencies on WGL_ARB_pbuffer

Ignore the "Additions to the WGL Specification" section if WGL_ARB_pbuffer is not supported.

Dependencies on WGL_ARB_pixel_format

    The WGL_ARB_pixel_format extension must be used to determine a
    pixel format with unsigned float components.

Dependencies on ARB_color_buffer_float

    If ARB_color_buffer_float is not supported, replace this amended
    sentence from 4.3.2 above

    For an RGBA color, if <type> is not one of FLOAT,
    UNSIGNED_INT_5_9_9_9_REV_EXT, or UNSIGNED_INT_10F_11F_11F_REV_EXT,
    or if the CLAMP_READ_COLOR_ARB is TRUE, or CLAMP_READ_COLOR_ARB
    is FIXED_ONLY_ARB and the selected color (or texture) buffer is
    a fixed-point buffer, each component is first clamped to [0,1]."

    with

    "For an RGBA color, if <type> is not one of FLOAT,
    UNSIGNED_INT_5_9_9_9_REV_EXT, or UNSIGNED_INT_10F_11F_11F_REV_EXT
    and the selected color buffer (or texture image for GetTexImage)
    is a fixed-point buffer (or texture image for GetTexImage), each
    component is first clamped to [0,1]."

Dependencies on EXT_texture_shared_exponent

    If EXT_texture_shared_exponent is not supported, delete the reference
    to UNSIGNED_INT_5_9_9_9_REV_EXT in section 4.3.2.

Dependencies on EXT_framebuffer_object

    If EXT_framebuffer_object is not supported, then
    RenderbufferStorageEXT is not supported and the R11F_G11F_B10F_EXT
    internalformat is therefore not supported by RenderbufferStorageEXT.

    If EXT_framebuffer_object is supported, glRenderbufferStorageEXT
    accepts GL_RG11F_B10F_EXT for its internalformat parameter because
    GL_RG11F_B10F_EXT has a base internal format of GL_RGB that is listed
    as color-renderable by the EXT_framebuffer_object specification.

Errors

    Relaxation of INVALID_ENUM errors

    TexImage1D, TexImage2D, TexImage3D, CopyTexImage1D, CopyTexImage2D,
    and RenderbufferStorageEXT accept the new R11F_G11F_B10F_EXT token
    for internalformat.

    DrawPixels, ReadPixels, TexImage1D, TexImage2D, GetTexImage,
    TexImage3D, TexSubImage1D, TexSubImage2D, TexSubImage3D,
    GetHistogram, GetMinmax, ConvolutionFilter1D, ConvolutionFilter2D,
    ConvolutionFilter3D, GetConvolutionFilter, SeparableFilter2D,
    GetSeparableFilter, ColorTable, ColorSubTable, and GetColorTable
    accept the new UNSIGNED_INT_10F_11F_11F_REV_EXT token for type.

New errors

INVALID_OPERATION is generated by DrawPixels, ReadPixels, TexImage1D, TexImage2D, GetTexImage, TexImage3D, TexSubImage1D, TexSubImage2D, TexSubImage3D, GetHistogram, GetMinmax, ConvolutionFilter1D, ConvolutionFilter2D, ConvolutionFilter3D, GetConvolutionFilter, SeparableFilter2D, GetSeparableFilter, ColorTable, ColorSubTable, and GetColorTable if <type> is UNSIGNED_INT_10F_11F_11F_REV_EXT and <format> is not RGB.

New State

In table 6.17, Textures (page 278), increment the 42 in "n x Z42*" by 1 for the R11F_G11F_B10F_EXT format.

[NOTE: The OpenGL 2.0 specification actually should read "n x Z48*" because of the 6 generic compressed internal formats in table 3.18.]

(modify table 6.33, p. 294)

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
RGBA_SIGNED_COMPONENTS_EXT	4xB	GetIntegerv	-	True if respective R, G, B, and A components are signed	4	-

New Implementation Dependent State

None

Issues

1) What should this extension be called?

RESOLVED: EXT_packed_float

This extension provides a new 3-component packed float format for use as a texture internal format, pixel external format, and framebuffer color format.

"packed" indicates the extension is packing components at reduced precisions (similar to EXT_packed_pixels or NV_packed_depth_stencil).

EXT_r11f_g11f_b10f_float was considered but there's no precedent for extension names to be so explicit (or cryptic?) about format specifics in the extension name.

2) Should there be an rgb11f_b10f framebuffer format?

RESOLVED: Yes. Unsigned floating-point rendering formats for GLX and WGL are provided. The assumption is that this functionality could be used to advertise a pixel format with 11 bits of unsigned floating-point red, 11 bits of unsigned floating-point green, and 10 bits of floating-point blue.

In theory, an implementation could advertise other component sizes other than 11/11/10 for an unsigned floating-point framebuffer format but that is not expected.

3) *Should there be GLX and WGL extension strings?*

RESOLVED: Yes, there are WGL and GLX tokens added to support querying unsigned floating-point color buffer formats named WGL_EXT_pixel_format_packed_float and GLX_EXT_fbconfig_packed_float respectively.

4) *Should there be an unequal distribution of red, green, and blue mantissa bits?*

RESOLVED: Yes. A 6-bit mantissa for red and green is unbalanced with the 5-bit mantissa for blue, but this allows all the bits of a 32 bit word (6+6+5+3*5=32) to be used. The blue component is chosen to have fewer bits because 1) it is the third component, and 2) there's a belief that the human eye is less sensitive to blue variations..

Developers should be aware that subtle yellowing or bluing of gray-scale values is possible because of the extra bit of mantissa in the red and green components.

5) *Should there be an external format for r11f_g11f_b10f?*

RESOLVED: Yes. This makes it fast to load GL_R11F_G11F_B10F_EXT textures without any translation by the driver.

6) *What is the exponent bias?*

RESOLVED: 15, just like 16-bit half-precision floating-point values.

7) *Can s10e5 floating-point filtering be used to filter r11f_g11f_b10f values? If so, how?*

RESOLVED: Yes. It is easy to promote r11f_g11f_b10f values to s10e5 components.

8) *Should automatic mipmap generation be supported for r11f_g11f_b10f textures?*

RESOLVED: Yes.

9) *Should non-texture and non-framebuffer commands for loading pixel data accept the GL_UNSIGNED_INT_10F_11F_11F_REV_EXT type?*

RESOLVED: Yes.

Once the pixel path has to support the new type/format combination of GL_UNSIGNED_INT_5_9_9_9_REV_EXT / GL_RGB for specifying and querying texture images, it might as well be supported for all commands that pack and unpack RGB pixel data.

The specification is written such that the glDrawPixels type/format parameters are accepted by glReadPixels, glTexGetImage, glTexImage2D, and other commands that are specified in terms of glDrawPixels.

10) *Should non-texture internal formats (such as for color tables, convolution kernels, histogram bins, and min/max tables) accept GL_R11F_G11F_B10F_EXT format?*

RESOLVED: No.

That's pointless. No hardware is ever likely to support GL_R11F_G11F_B10F_EXT internal formats for anything other than textures and maybe color buffers in the future. This format is not interesting for color tables, convolution kernels, etc.

11) *Should a format be supported with sign bits for each component?*

RESOLVED: No. A sign bit for each of the three components would steal too many bits from the mantissa. This format is intended for storing radiance and irradiance values that are physically non-negative.

12) *Should we support a non-REV version of the GL_UNSIGNED_INT_10F_11F_11F_REV_EXT token?*

RESOLVED: No. We don't want to promote different arrangements of the bitfields for r11f_g11f_b10f values.

13) *Can you use the GL_UNSIGNED_INT_10F_11F_11F_REV_EXT format with just any format?*

RESOLVED: You can only use the GL_UNSIGNED_INT_10F_11F_11F_REV_EXT format with GL_RGB. Otherwise, the GL generates an GL_INVALID_OPERATION error. Just as the GL_UNSIGNED_BYTE_3_3_2 format just works with GL_RGB (or else the GL generates an GL_INVALID_OPERATION error), so should GL_UNSIGNED_INT_10F_11F_11F_REV_EXT.

14) *Should blending be supported for a packed float framebuffer format?*

RESOLVED: Yes. Blending is required for other floating-point framebuffer formats introduced by ARB_color_buffer_float. The equations for blending should be evaluated with signed floating-point math but the result will have to be clamped to non-negative values to be stored back into the packed float format of the color buffer.

15) *Should unsigned floating-point framebuffers be queried differently from conventional (signed) floating-point framebuffers?*

RESOLVED: Yes. An existing application using ARB_color_buffer_float can rightfully expect a floating-point color buffer format to provide signed components. The packed float format does not provide a sign bit. Simply treating packed float color buffer formats as floating-point might break some existing applications that depend on a float color buffer to be signed.

For this reason, there are new WGL_TYPE_RGBA_UNSIGNED_FLOAT_EXT (for WGL) and GLX_RGBA_UNSIGNED_FLOAT_BIT_EXT (for GLX) framebuffer format parameters.

16) *What should glGet of GL_RGBA_FLOAT_MODE_ARB return for unsigned float color buffer formats?*

RESOLVED. GL_RGBA_FLOAT_MODE_ARB should return true. The packed float components are unsigned but still floating-point.

17) *Can you query with glGet to determine if the color buffer has unsigned float components?*

RESOLVED: Yes. Call glGetIntegerv on GL_RGBA_SIGNED_COMPONENTS_EXT. The value returned is a 4-element array. Element 0 corresponds to red, element 1 corresponds to green, element 2 corresponds to blue, and element 3 corresponds to alpha. If a color component is signed, its corresponding element is true (GL_TRUE). This is the same way the GL_COLOR_WRITEMASK bits are formatted.

For the packed float format, all the elements are zeroed since the red, green, and blue components are unsigned and the alpha component is non-existent. All elements are also zeroed for conventional fixed-point color buffer formats. Elements are set for signed floating-point formats such as those introduced by ARB_color_buffer_float. If a component (such as alpha) has zero bits, the component should not be considered signed and so the bit for the respective component should be zeroed.

This generality allows a future extension to specify float color buffer formats that had a mixture of signed and unsigned floating-point components. However, this extension only provides a packed float color format with all unsigned components.

18) *How many bits of alpha should GL_ALPHA_BITS return for the packed float color buffer format?*

RESOLVED: Zero.

19) *Can you render to a packed float texture with the EXT_framebuffer_object functionality?*

RESOLVED: Yes.

Potentially an implementation could return GL_FRAMEBUFFER_UNSUPPORTED_EXT when glCheckFramebufferStatusEXT for a framebuffer object including a packed float color buffer, but implementations are likely to support (and strongly encouraged to support) the packed float format for use with a framebuffer object because the packed float format is expected to be a memory-efficient floating-point color format well-suited for rendering, particularly rendering involving high-dynamic range.

20) *This extension is for a particular packed float format. What if new packed float formats come along?*

RESOLVED: A new extension could be introduced with a name like EXT_packed_float2, but at this time, no other such extensions are expected except for the EXT_texture_shared_exponent extension. It simply hard to justify packing three or more components into a single 32-bit word in lots of different ways since any approach is going to be a compromise of some sort. For two-component or one-component floating-point formats, the existing ARB_texture_float formats fit nicely into 16 or 32 bits by simply using half precision floating-point. If 64 bits are allowed for a pixel, the GL_RGBA16F_ARB is a good choice.

The packed float format is similar to the format introduced by the EXT_texture_shared_exponent extension, but that extension is not a pure packed float format. Unlike the packed float format, the EXT_texture_shared_exponent format shares a single exponent between the RGB components rather than providing an independent exponent for each component. Because the EXT_texture_shared_exponent uses fewer bits to store exponent values, more mantissa precision is provided.

21) *Should this extension provide pbuffer support?*

RESOLVED: Yes. Pbuffers are core GLX 1.3 functionality. While using FBO is probably the preferred way to render to r11f_g11f_b10f framebuffers but pbuffer support is natural to provide. WGL should have r11f_g11f_b10f pbuffer support too.

22) *Must an implementation support NaN, Infinity, and/or denorms?*

RESOLVED: The preferred implementation is to support NaN, Infinity, and denorms. Implementations are allowed to flush denorms to zero, and treat NaN and Infinity values as large finite values.

This allowance flushes denorms to zero:

```
    0.0,                      if E == 0 and M != 0
```

This allowance treats Infinity as a finite value:

```
    2^16                      if E == 31 and M == 0
```

This allowance treats NaN encodings as finite values:

```
    2^16 * (1 + M/64)         if E == 31 and M != 0
```

The expectation is that mainstream GPUs will support NaN, Infinity, and denorms while low-end implementations such as for OpenGL ES 2.0 will likely support denorms but neither NaN nor Infinity.

    There is not an indication of how these floating-point special
    values are treated (though an application could test an
    implementation if necessary).

23) *Should this extension interoperate with framebuffer objects?*

    RESOLVED: Definitely. No particular specification language is
    required.

    In particular, glRenderbufferStorageEXT should accept
    GL_R11F_G11F_B10F_EXT for its internalformat parameter (true
    because this extension adds a new format to Table 3.16).

24) *Are negative color components clamped to zero when written into
    an unsigned floating-point color buffer? If so, do we need to
    say in the Blending or Dithering language that negative color
    components are clamped to zero?*

    RESOLVED: Yes, negative color components are clamped to
    zero when written to an unsigned floating-point color buffer.
    No specification language is required for this behavior because
    the ARB_color_buffer_float extension says

    "In RGBA mode dithering selects, for each color component, either
    the most positive representable color value (for that particular
    color component) that is less than or equal to the incoming
    color component value, c, or the most negative representable
    color value that is greater than or equal to c.

    If dithering is disabled, then each incoming color component
    c is replaced with the most positive representable color value
    (for that particular component) that is less than or equal to c,
    or by the most negative representable value, if no representable
    value is less than or equal to c;"

    The most negative representable value for unsigned
    floating-point values is zero. So the existing language from
    ARB_color_buffer_float already indicates that negative values
    are clamped to zero for unsigned floating-point color buffers.
    No additional specification language is required.

25) *Prior texture internal formats have generic formats (example:
    GL_RGB) and corresponding sized formats (GL_RGB8, GL_RGB10,
    etc.). Should we add a generic format corresponding to
    GL_R11F_G11F_B10F_EXT?*

    RESOLVED: No. It's unlikely there will be any other unsigned
    floating-point texture formats.

Overview

```
This extension provides support for packed pixels in host memory.  A
packed pixel is represented entirely by one unsigned byte, one
unsigned short, or one unsigned integer.  The fields with the packed
pixel are not proper machine types, but the pixel as a whole is.  Thus
the pixel storage modes, including PACK_SKIP_PIXELS, PACK_ROW_LENGTH,
PACK_SKIP_ROWS, PACK_IMAGE_HEIGHT_EXT, PACK_SKIP_IMAGES_EXT,
PACK_SWAP_BYTES, PACK_ALIGNMENT, and their unpacking counterparts all
work correctly with packed pixels.
```

Additions to Chapter 2 of the 1.0 Specification (OpenGL Operation)

None

Additions to Chapter 3 of the 1.0 Specification (Rasterization)

The five tokens defined by this extension are added to Table 3.4:

<type> Parameter Token Value	Corresponding GL Data Type	Special Interpretation
UNSIGNED_BYTE	ubyte	No
BYTE	byte	No
UNSIGNED_SHORT	ushort	No
SHORT	short	No
UNSIGNED_INT	uint	No
INT	int	No
FLOAT	float	No
BITMAP	ubyte	Yes
UNSIGNED_BYTE_3_3_2_EXT	ubyte	Yes
UNSIGNED_SHORT_4_4_4_4_EXT	ushort	Yes
UNSIGNED_SHORT_5_5_5_1_EXT	ushort	Yes
UNSIGNED_INT_8_8_8_8_EXT	uint	Yes
UNSIGNED_INT_10_10_10_2_EXT	uint	Yes

Table 3.4: DrawPixels and ReadPixels <type> parameter values and the corresponding GL data types. Refer to table 2.2 for definitions of GL data types. Special interpretations are described near the end of section 3.6.3.

[Section 3.6.3 of the GL Specification (Rasterization of Pixel Rectangles) is rewritten as follows:]

3.6.3 Rasterization of Pixel Rectangles

The process of drawing pixels encoded in host memory is diagrammed in Figure 3.7. We describe the stages of this process in the order in which they occur.

Pixels are drawn using

```
    void DrawPixels(sizei width,
                    sizei height,
                    enum format,
                    enum type,
                    void* data);
```

<format> is a symbolic constant indicating what the values in memory represent. <width> and <height> are the width and height, respectively, of the pixel rectangle to be drawn. <data> is a pointer to the data to be drawn. These data are represented with one of seven GL data types, specified by <type>. The correspondence between the thirteen <type> token values and the GL data types they indicate is given in Table 3.4. If the GL is in color index mode and <format> is not one of COLOR_INDEX, STENCIL_INDEX, or DEPTH_COMPONENT, then the error INVALID_OPERATION

occurs. Some additional constraints on the combinations of <format> and <type> values that are accepted are discussed below.

Unpacking

Data are taken from host memory as a sequence of signed or unsigned bytes (GL data types byte and ubyte), signed or unsigned short integers (GL data types short and ushort), signed or unsigned integers (GL data types int and uint), or floating-point values (GL data type float). These elements are grouped into sets of one, two, three, four, or five values, depending on the <format>, to form a group. Table 3.5 summarizes the format of groups obtained from memory. It also indicates those formats that yield indices and those that yield components.

Format Name	Target Buffer	Element Meaning and Order
COLOR_INDEX	Color	Color index
STENCIL_INDEX	Stencil	Stencil index
DEPTH_COMPONENT	Depth	Depth component
RED	Color	R component
GREEN	Color	G component
BLUE	Color	B component
ALPHA	Color	A component
RGB	Color	R, G, B components
RGBA	Color	R, G, B, A components
ABGR_EXT	Color	A, B, G, R components
CMYK_EXT	Color	Cyan, Magenta, Yellow, Black components
CMYKA_EXT	Color	Cyan, Magenta, Yellow, Black, A components
LUMINANCE	Color	Luminance component
LUMINANCE_ALPHA	Color	Luminance, A components

Table 3.5: DrawPixels and ReadPixels formats. The third column gives a description of and the number and order of elements in a group.

By default the values of each GL data type are interpreted as they would be specified in the language of the client's GL binding. If UNPACK_SWAP_BYTES is set to TRUE, however, then the values are interpreted with the bit orderings modified as per the table below. The modified bit orderings are defined only if the GL data type ubyte has eight bits, and then for each specific GL data type only if that type is represented with 8, 16, or 32 bits.

Element Size	Default Bit Ordering	Modified Bit Ordering
8-bit	[7..0]	[7..0]
16-bit	[15..0]	[7..0] [15..8]
32-bit	[31..0]	[7..0] [15..8] [23..16] [31..24]

Table: Bit ordering modification of elements when UNPACK_SWAP_BYTES is TRUE. These reorderings are defined only when GL data type ubyte has 8 bits, and then only for GL data types with 8, 16, or 32 bits.

The groups in memory are treated as being arranged in a rectangle. This rectangle consists of a series of rows, with the first element of the first group of the first row pointed to by the pointer passed to DrawPixels. If the value of UNPACK_ROW_LENGTH is not positive, then the number of groups in a row is <width>; otherwise the number of groups is UNPACK_ROW_LENGTH. If the first element of the first row is at location p in memory, then the location of the first element of the Nth row is

```
    p + Nk
```

where N is the row number (counting from zero) and k is defined as

```
         / nl                        s >= a
    k = <
         \ a/s * ceiling(snl/a)      s < a
```

where n is the number of elements in a group, l is the number of groups in a row, a is the value of UNPACK_ALIGNMENT, and s is the size, in units of GL ubytes, of an element. If the number of bits per element is not 1, 2, 4, or 8 times the number of bits in a GL ubyte, then k = nl for all values of a.

There is a mechanism for selecting a sub-rectangle of groups from a larger containing rectangle. This mechanism relies on three integer parameters: UNPACK_ROW_LENGTH, UNPACK_SKIP_ROWS, and UNPACK_SKIP_PIXELS. Before obtaining the first group from memory, the pointer supplied to DrawPixels is effectively advanced by

```
    UNPACK_SKIP_PIXELS * n + UNPACK_SKIP_ROWS * k
```

elements. Then <width> groups are obtained from contiguous elements in memory (without advancing the pointer), after which the pointer is advanced by k elements. <height> sets of <width> groups of values are obtained this way. See Figure 3.8.

Calling DrawPixels with a <type> of UNSIGNED_BYTE_3_3_2, UNSIGNED_SHORT_4_4_4_4, UNSIGNED_SHORT_5_5_5_1, UNSIGNED_INT_8_8_8_8, or UNSIGNED_INT_10_10_10_2 is a special case in which all the elements of each group are packed into a single unsigned byte, unsigned short, or unsigned int, depending on the type. The number of elements per packed pixel is fixed by the type, and must match the number of elements per group indicated by the <format> parameter. (See the table below.) The error INVALID_OPERATION is generated if a mismatch occurs.

<type> Parameter Token Name	GL Data Type	Number of Elements	Matching Pixel Formats
UNSIGNED_BYTE_3_3_2_EXT	ubyte	3	RGB
UNSIGNED_SHORT_4_4_4_4_EXT	ushort	4	RGBA,ABGR_EXT,CMYK_EXT
UNSIGNED_SHORT_5_5_5_1_EXT	ushort	4	RGBA,ABGR_EXT,CMYK_EXT
UNSIGNED_INT_8_8_8_8_EXT	uint	4	RGBA,ABGR_EXT,CMYK_EXT
UNSIGNED_INT_10_10_10_2_EXT	uint	4	RGBA,ABGR_EXT,CMYK_EXT

Bitfield locations of the first, second, third, and fourth elements of each packed pixel type are illustrated in the diagrams below. Each bitfield is interpreted as an unsigned integer value. If the base GL type is supported with more than the minimum precision (e.g. a 9-bit byte) the packed elements are right-justified in the pixel.

```
UNSIGNED_BYTE_3_3_2_EXT:

      7   6   5   4   3   2   1   0
    +-----------+-----------+-------+
    |           |           |       |
    +-----------+-----------+-------+

       first       second     third
       element     element    element

UNSIGNED_SHORT_4_4_4_4_EXT:

    +-------------------+-------------------+-------------------+---+
    |                   |                   |                   |   |
    +-------------------+-------------------+-------------------+---+

        first                second              third           fourth
        element              element             element         element

UNSIGNED_INT_8_8_8_8_EXT:

   31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
  +-----------------------+-----------------------+-----------------------+-----------------------+
  |                       |                       |                       |                       |
  +-----------------------+-----------------------+-----------------------+-----------------------+

        first                   second                  third                   fourth
        element                 element                 element                 element

UNSIGNED_INT_10_10_10_2_EXT:

   31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
  +-----------------------------+-----------------------------+-----------------------------+-----+
  |                             |                             |                             |     |
  +-----------------------------+-----------------------------+-----------------------------+-----+

         first                        second                        third               fourth
         element                      element                       element             element
```

The assignment of elements to fields in the packed pixel is as described in the table below:

Format	First Element	Second Element	Third Element	Fourth Element
RGB	red	green	blue	
RGBA	red	green	blue	alpha
ABGR_EXT	alpha	blue	green	red
CMYK_EXT	cyan	magenta	yellow	black

Byte swapping, if enabled, is performed before the elements are extracted from each pixel. The above discussions of row length and image extraction are valid for packed pixels, if "group" is substituted for "element" and the number of elements per group is understood to be one.

Calling DrawPixels with a <type> of BITMAP is a special case in which the data are a series of GL ubyte values. Each ubyte value specifies 8 1-bit elements with its 8 least-significant bits. The 8 single-bit elements are ordered from most significant to least significant if the value of UNPACK_LSB_FIRST is FALSE; otherwise, the ordering is from least significant to most significant. The values of bits other than the 8 least significant in each ubyte are not significant.

The first element of the first row is the first bit (as defined above) of the ubyte pointed to by the pointer passed to DrawPixels. The first element of the second row is the first bit (again as defined above) of the ubyte at location p+k, where k is computed as

```
    k = a * ceiling(nl/8a)
```

There is a mechanism for selecting a sub-rectangle of elements from a BITMAP image as well. Before obtaining the first element from memory, the pointer supplied to DrawPixels is effectively advanced by

```
    UNPACK_SKIP_ROWS * k
```

ubytes. Then UNPACK_SKIP_PIXELS 1-bit elements are ignored, and the subsequent <width> 1-bit elements are obtained, without advancing the ubyte pointer, after which the pointer is advanced by k ubytes. <height> sets of <width> elements are obtained this way.

Conversion to floating-point

This step applies only to groups of components. It is not performed on indices. Each element in a group is converted to a floating-point value according to the appropriate formula in Table 2.4 (section 2.12). Unsigned integer bitfields extracted from packed pixels are interpreted using the formula

```
    f = c / ((2**N)-1)
```

where c is the value of the bitfield (interpreted as an unsigned integer), N is the number of bits in the bitfield, and the division is performed in floating point.

[End of changes to Section 3.6.3]

If this extension is supported, all commands that accept pixel data also accept packed pixel data. These commands are DrawPixels, TexImage1D, TexImage2D, TexImage3DEXT, TexSubImage1DEXT, TexSubImage2DEXT, TexSubImage3DEXT, ConvolutionFilter1DEXT, ConvolutionFilter2DEXT, ConvolutionFilter3DEXT, SeparableFilter2DEXT, SeparableFilter3DEXT, ColorTableSGI, TexImage4DSGIS, and TexSubImage4DSGIS.

Additions to Chapter 4 of the 1.0 Specification (Per-Fragment Operations and the Framebuffer)

[Make the following changes to Section 4.3.2 (Reading Pixels):]

Final Conversion

For an index, if the <type> is not FLOAT, final conversion consists of masking the index with the value given in Table 4.6; if the <type> is FLOAT, then the integer index is converted to a GL float data value. For a component, each component is first clamped to [0,1]. Then, the appropriate conversion formula from Table 4.7 is applied to the component.

<type> Parameter	Index Mask
UNSIGNED_BYTE	2**8 - 1
BITMAP	1
BYTE	2**7 - 1
UNSIGNED_SHORT	2**16 - 1
SHORT	2**15 - 1
UNSIGNED_INT	2**32 - 1
INT	2**31 - 1

Table 4.6: Index masks used by ReadPixels. Floating point data are not masked.

<type> Parameter	GL Data Type	Component Conversion Formula
UNSIGNED_BYTE	ubyte	c = ((2**8)-1)*f
BYTE	byte	c = (((2**8)-1)*f-1)/2
UNSIGNED_SHORT	ushort	c = ((2**16)-1)*f
SHORT	short	c = (((2**16)-1)*f-1)/2
UNSIGNED_INT	uint	c = ((2**32)-1)*f
INT	int	c = (((2**32)-1)*f-1)/2
FLOAT	float	c = f
UNSIGNED_BYTE_3_3_2_EXT	ubyte	c = ((2**N)-1)*f
UNSIGNED_SHORT_4_4_4_4_EXT	ushort	c = ((2**N)-1)*f
UNSIGNED_SHORT_5_5_5_1_EXT	ushort	c = ((2**N)-1)*f
UNSIGNED_INT_8_8_8_8_EXT	uint	c = ((2**N)-1)*f
UNSIGNED_INT_10_10_10_2_EXT	uint	c = ((2**N)-1)*f

Table 4.7: Reversed component conversions - used when component data are being returned to client memory. Color, normal, and depth components are converted from the internal floating-point representation (f) to a datum of the specified GL data type (c) using the equations in this table. All arithmetic is done in the internal floating point format. These conversions apply to component data returned by GL query commands and to components of pixel data returned to client memory. The equations remain the same even if the implemented ranges of the GL data types are greater than the minimum required ranges. (Refer to table 2.2.) Equations with N as the exponent are performed for each bitfield of the packed data type, with N set to the number of bits in the bitfield.

Placement in Client Memory

Groups of elements are placed in memory just as they are taken from memory for DrawPixels. That is, the ith group of the jth row (corresponding to the ith pixel in the jth row) is placed in memory must where the ith group of the jth row would be taken from for DrawPixels. See Unpacking under section 3.6.3. The only difference is that the storage mode parameters whose names begin with PACK_ are used instead of those whose names begin with UNPACK_.

[End of changes to Section 4.3.2]

If this extension is supported, all commands that return pixel data also return packed pixel data. These commands are ReadPixels, GetTexImage, GetHistogramEXT, GetMinmaxEXT, GetConvolutionFilterEXT, GetSeparableFilterEXT, and GetColorTableSGI.

Dependencies on EXT_abgr

If EXT_abgr is not implemented, then the references to ABGR_EXT in this file are invalid, and should be ignored.

Dependencies on EXT_texture3D

If EXT_texture3D is not implemented, then the references to TexImage3DEXT in this file are invalid, and should be ignored.

Dependencies on EXT_subtexture

If EXT_subtexture is not implemented, then the references to TexSubImage1DEXT, TexSubImage2DEXT, and TexSubImage3DEXT in this file are invalid, and should be ignored.

Dependencies on EXT_histogram

If EXT_histogram is not implemented, then the references to GetHistogramEXT and GetMinmaxEXT in this file are invalid, and should be ignored.

Dependencies on EXT_convolution

If EXT_convolution is not implemented, then the references to ConvolutionFilter1DEXT, ConvolutionFilter2DEXT, ConvolutionFilter3DEXT, GetConvolutionFilterEXT, SeparableFilter2DEXT, SeparableFilter3DEXT, and GetSeparableFilterEXT in this file are invalid, and should be ignored.

Dependencies on SGI_color_table

If SGI_color_table is not implemented, then the references to ColorTableSGI and GetColorTableSGI in this file are invalid, and should be ignored.

Dependencies on SGIS_texture4D

If SGIS_texture4D is not implemented, then the references to TexImage4DSGIS and TexSubImage4DSGIS in this file are invalid, and should be ignored.

Dependencies on EXT_cmyka

If EXT_cmyka is not implemented, then the references to CMYK_EXT and CMYKA_EXT in this file are invalid, and should be ignored.

Errors

[For the purpose of this enumeration of errors, GenericPixelFunction represents any OpenGL function that accepts or returns pixel data, using parameters <type> and <format> to define the type and format of that data. Currently these functions are DrawPixels, ReadPixels, TexImage1D, TexImage2D, GetTexImage, TexImage3DEXT, TexSubImage1DEXT, TexSubImage2DEXT, TexSubImage3DEXT, GetHistogramEXT, GetMinmaxEXT, ConvolutionFilter1DEXT, ConvolutionFilter2DEXT, ConvolutionFilter3DEXT, GetConvolutionFilterEXT, SeparableFilter2DEXT, SeparableFilter3DEXT, GetSeparableFilterEXT, ColorTableSGI, GetColorTableSGI, TexImage4DSGIS, and TexSubImage4DSGIS.]

INVALID_OPERATION is generated by GenericPixelFunction if its <type> parameter is UNSIGNED_BYTE_3_3_2_EXT and its <format> parameter does not specify three components. Currently the only 3-component format is RGB.

INVALID_OPERATION is generated by GenericPixelFunction if its <type> parameter is UNSIGNED_SHORT_4_4_4_4_EXT, UNSIGNED_SHORT_5_5_5_1_EXT, UNSIGNED_INT_8_8_8_8_EXT, or UNSIGNED_INT_10_10_10_2_EXT and its <format> parameter does not specify four components. Currently the only 4-component formats are RGBA, ABGR_EXT, and CMYK_EXT.

Support

```
    Intel 810/815.

    Mesa.

    Microsoft software OpenGL implementation.

    Selected NVIDIA GPUs: NV1x (GeForce 256, GeForce2, GeForce4 MX,
    GeForce4 Go, Quadro, Quadro2), NV2x (GeForce3, GeForce4 Ti,
    Quadro DCC, Quadro4 XGL), and NV3x (GeForce FX 5xxxx, Quadro FX
    1000/2000/3000).  NV3 (Riva 128) and NV4 (TNT, TNT2) GPUs and NV4x
    GPUs do NOT support this functionality (no hardware support).
    Future NVIDIA GPU designs will no longer support paletted textures.

    S3 ProSavage, Savage 2000.

    3Dfx Voodoo3, Voodoo5.

    3Dlabs GLINT.
```

Dependencies

```
    GL_EXT_paletted_texture shares routines and enumerants with
    GL_SGI_color_table with the minor modification that EXT replaces SGI.
    In all other ways these calls should function in the same manner and the
    enumerant values should be identical.  The portions of
    GL_SGI_color_table that are used are:

                ColorTableSGI, GetColorTableSGI, GetColorTableParameterivSGI,
                GetColorTableParameterfvSGI.
                COLOR_TABLE_FORMAT_SGI, COLOR_TABLE_WIDTH_SGI,
                COLOR_TABLE_RED_SIZE_SGI, COLOR_TABLE_GREEN_SIZE_SGI,
                COLOR_TABLE_BLUE_SIZE_SGI, COLOR_TABLE_ALPHA_SIZE_SGI,
                COLOR_TABLE_LUMINANCE_SIZE_SGI, COLOR_TABLE_INTENSITY_SIZE_SGI.
    Portions of GL_SGI_color_table which are not used in
    GL_EXT_paletted_texture are:

                CopyColorTableSGI, ColorTableParameterivSGI,
                ColorTableParameterfvSGI.
                COLOR_TABLE_SGI, POST_CONVOLUTION_COLOR_TABLE_SGI,
                POST_COLOR_MATRIX_COLOR_TABLE_SGI, PROXY_COLOR_TABLE_SGI,
                PROXY_POST_CONVOLUTION_COLOR_TABLE_SGI,
                PROXY_POST_COLOR_MATRIX_COLOR_TABLE_SGI, COLOR_TABLE_SCALE_SGI,
                COLOR_TABLE_BIAS_SGI.

    EXT_paletted_texture can be used in conjunction with EXT_texture3D.
    EXT_paletted_texture modifies TexImage3DEXT to accept paletted image
    data and allows TEXTURE_3D_EXT and PROXY_TEXTURE_3D_EXT to be used a
    targets in the color table routines.  If EXT_texture3D is unsupported
    then references to 3D texture support in this spec are invalid and
    should be ignored.

    EXT_paletted_texture can be used in conjunction with
    ARB_texture_cube_map.  EXT_paletted_texture modifies TexImage2D
    to accept paletted image data and allows TEXTURE_CUBE_MAP_ARB, and
    PROXY_TEXTURE_CUBE_MAP_ARB to be used a targets in the color table
    routines.  If ARB_texture_cube_map is unsupported then references
    to cube map texture support in this spec are invalid and should be
    ignored.
```

Overview

```
    EXT_paletted_texture defines new texture formats and new calls to
    support the use of paletted textures in OpenGL.  A paletted texture is
    defined by giving both a palette of colors and a set of image data which
    is composed of indices into the palette.  The paletted texture cannot
    function properly without both pieces of information so it increases the
    work required to define a texture.  This is offset by the fact that the
    overall amount of texture data can be reduced dramatically by factoring
    redundant information out of the logical view of the texture and placing
    it in the palette.

    Paletted textures provide several advantages over full-color textures:

    * As mentioned above, the amount of data required to define a
    texture can be greatly reduced over what would be needed for full-color
    specification.  For example, consider a source texture that has only 256
    distinct colors in a 256 by 256 pixel grid.  Full-color representation
    requires three bytes per pixel, taking 192K of texture data.  By putting
    the distinct colors in a palette only eight bits are required per pixel,
    reducing the 192K to 64K plus 768 bytes for the palette.  Now add an
    alpha channel to the texture.  The full-color representation increases
    by 64K while the paletted version would only increase by 256 bytes.
    This reduction in space required is particularly important for hardware
    accelerators where texture space is limited.

    * Paletted textures allow easy reuse of texture data for images
    which require many similar but slightly different colored objects.
    Consider a driving simulation with heavy traffic on the road.  Many of
    the cars will be similar but with different color schemes.  If
    full-color textures are used a separate texture would be needed for each
```

color scheme, while paletted textures allow the same basic index data to be reused for each car, with a different palette to change the final colors.

* Paletted textures also allow use of all the palette tricks developed for paletted displays. Simple animation can be done, along with strobing, glowing and other palette-cycling effects. All of these techniques can enhance the visual richness of a scene with very little data.

New Procedures and Functions

```
    void ColorTableEXT(
        enum target,
        enum internalFormat,
        sizei width,
        enum format,
        enum type,
        const void *data);

    void ColorSubTableEXT(
        enum target,
        sizei start,
        sizei count,
        enum format,
        enum type,
        const void *data);

    void GetColorTableEXT(
        enum target,
        enum format,
        enum type,
        void *data);

    void GetColorTableParameterivEXT(
        enum target,
        enum pname,
        int *params);

    void GetColorTableParameterfvEXT(
        enum target,
        enum pname,
        float *params);
```

New Tokens

```
    Accepted by the internalformat parameter of TexImage1D, TexImage2D and
    TexImage3DEXT:
        COLOR_INDEX1_EXT                0x80E2
        COLOR_INDEX2_EXT                0x80E3
        COLOR_INDEX4_EXT                0x80E4
        COLOR_INDEX8_EXT                0x80E5
        COLOR_INDEX12_EXT               0x80E6
        COLOR_INDEX16_EXT               0x80E7
    Accepted by the pname parameter of GetColorTableParameterivEXT and
    GetColorTableParameterfvEXT:
        COLOR_TABLE_FORMAT_EXT          0x80D8
        COLOR_TABLE_WIDTH_EXT           0x80D9
        COLOR_TABLE_RED_SIZE_EXT        0x80DA
        COLOR_TABLE_GREEN_SIZE_EXT      0x80DB
        COLOR_TABLE_BLUE_SIZE_EXT       0x80DC
        COLOR_TABLE_ALPHA_SIZE_EXT      0x80DD
        COLOR_TABLE_LUMINANCE_SIZE_EXT  0x80DE
        COLOR_TABLE_INTENSITY_SIZE_EXT  0x80DF

    Accepted by the value parameter of GetTexLevelParameter{if}v:
        TEXTURE_INDEX_SIZE_EXT          0x80ED

    Accepted by the target parameter of ColorTableEXT,
    GetColorTableParameterivEXT, and GetColorTableParameterfvEXT:
        TEXTURE_1D                      0x0DE0
        TEXTURE_2D                      0x0DE1
        TEXTURE_3D_EXT                  0x806F
        TEXTURE_CUBE_MAP_ARB            0x8513
        PROXY_TEXTURE_1D                0x8063
        PROXY_TEXTURE_2D                0x8064
        PROXY_TEXTURE_3D_EXT            0x8070
        PROXY_TEXTURE_CUBE_MAP_ARB      0x851B

    Accepted by the target parameter of ColorSubTableEXT and
    GetColorTableEXT:
        TEXTURE_1D                      0x0DE0
        TEXTURE_2D                      0x0DE1
        TEXTURE_3D_EXT                  0x806F
        TEXTURE_CUBE_MAP_ARB            0x8513
```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

None

Additions to Chapter 3 of the GL Specification (Rasterization)

Section 3.6.4, 'Pixel Transfer Operations,' subsection 'Color Index Lookup,'

Point two is modified from 'The groups will be loaded as an image into texture memory' to 'The groups will be loaded as an image into texture memory and the internalformat parameter is not one of the color index formats from table 3.8.'

Section 3.8, 'Texturing,' subsection 'Texture Image Specification' is modified as follows:

The portion of the first paragraph discussing interpretation of format, type and data is split from the portion discussing target, width and height. The target, width and height section now ends with the sentence 'Arguments width and height specify the image's width and height.'

The format, type and data section is moved under a subheader 'Direct Color Texture Formats' and begins with 'If internalformat is not one of the color index formats from table 3.8,' and continues with the existing text through the internalformat discussion.

After that section, a new section 'Paletted Texture Formats' has the text:

If format is given as COLOR_INDEX then the image data is composed of integer values representing indices into a table of colors rather than colors themselves. If internalformat is given as one of the color index formats from table 3.8 then the texture will be stored internally as indices rather than undergoing index-to-RGBA mapping as would previously have occurred. In this case the only valid values for type are BYTE, UNSIGNED_BYTE, SHORT, UNSIGNED_SHORT, INT and UNSIGNED_INT.

The image data is unpacked from memory exactly as for a DrawPixels command with format of COLOR_INDEX for a context in color index mode. The data is then stored in an internal format derived from internalformat. In this case the only legal values of internalformat are COLOR_INDEX1_EXT, COLOR_INDEX2_EXT, COLOR_INDEX4_EXT, COLOR_INDEX8_EXT, COLOR_INDEX12_EXT and COLOR_INDEX16_EXT and the internal component resolution is picked according to the index resolution specified by internalformat. Any excess precision in the data is silently truncated to fit in the internal component precision.

An application can determine whether a particular implementation supports a particular paletted format (or any paletted formats at all) by attempting to use the paletted format with a proxy target. TEXTURE_INDEX_SIZE_EXT will be zero if the implementation cannot support the texture as given.

An application can determine an implementation's desired format for a particular paletted texture by making a TexImage call with COLOR_INDEX as the internalformat, in which case target must be a proxy target. After the call the application can query TEXTURE_INTERNAL_FORMAT to determine what internal format the implementation suggests for the texture image parameters. TEXTURE_INDEX_SIZE_EXT can be queried after such a call to determine the suggested index resolution numerically. The index resolution suggested by the implementation does not have to be as large as the input data precision. The resolution may also be zero if the implementation is unable to support any paletted format for the given texture image.

Table 3.8 should be augmented with a column titled 'Index bits.' All existing formats have zero index bits. The following formats are added with zeroes in all existing columns:

Name	Index bits
COLOR_INDEX1_EXT	1
COLOR_INDEX2_EXT	2
COLOR_INDEX4_EXT	4
COLOR_INDEX8_EXT	8
COLOR_INDEX12_EXT	12
COLOR_INDEX16_EXT	16

```
    At the end of the discussion of level the following text should be
    added:

      All mipmapping levels share the same palette.  If levels
      are created with different precision indices then their internal formats
      will not match and the texture will be inconsistent, as discussed above.

    In the discussion of internalformat for CopyTexImage{12}D, at end of the
    sentence specifying that 1, 2, 3 and 4 are illegal there should also be
    a mention that paletted internalformat values are illegal.

    At the end of the width, height, format, type and data section under
    TexSubImage there should be an additional sentence:

      If the target texture has an color index internal format
      then format may only be COLOR_INDEX.

    At the end of the first paragraph describing TexSubImage and
    CopyTexSubImage the following sentence should be added:

      If the target of a CopyTexSubImage is a paletted texture
      image then INVALID_OPERATION is returned.

    After the Alternate Image Specification Commands section, a new 'Palette
    Specification Commands' section should be added.

      Paletted textures require palette information to
      translate indices into full colors.  The command

        void ColorTableEXT(enum target, enum internalformat, sizei width,
                enum format, enum type, const void *data);

      is used to specify the format and size of the palette for paletted
      textures.  target specifies which texture is to have its palette
      changed and may be one of TEXTURE_1D, TEXTURE_2D, PROXY_TEXTURE_1D,
      PROXY_TEXTURE_2D, TEXTURE_3D_EXT, PROXY_TEXTURE_3D_EXT,
      TEXTURE_CUBE_MAP_ARB, or PROXY_TEXTURE_CUBE_MAP_ARB.  internalformat
      specifies the desired format and resolution of the palette when
      in its internal form.  internalformat can be any of the non-index
      values legal for TexImage internalformat although implementations
      are not required to support palettes of all possible formats.
      width controls the size of the palette and must be a power of two
      greater than or equal to one.  format and type specify the number
      of components and type of the data given by data.  format can be
      any of the formats legal for DrawPixels although implementations
      are not required to support all possible formats.  type can be
      any of the types legal for DrawPixels except GL_BITMAP.
      Data is taken from memory and converted just as if each
      palette entry were a single pixel of a 1D texture.  Pixel unpacking and
      transfer modes apply just as with texture data.  After unpacking and
      conversion the data is translated into a internal format that matches
      the given format as closely as possible.  An implementation does not,
      however, have a responsibility to support more than one precision for
      the base formats.

      If the palette's width is greater than than the range of
      the color indices in the texture data then some of the palettes entries
```

will be unused. If the palette's width is less than the range of the color indices in the texture data then the most-significant bits of the texture data are ignored and only the appropriate number of bits of the index are used when accessing the palette.

Specifying a proxy target causes the proxy texture's palette to be resized and its parameters set but no data is transferred or accessed. If an implementation cannot handle the palette data given in the call then the color table width and component resolutions are set to zero.

Portions of the current palette can be replaced with

```
void ColorSubTableEXT(enum target, sizei start, sizei count,
        enum format, enum type, const void *data);
```

target can be any of the non-proxy values legal for ColorTableEXT. start and count control which entries of the palette are changed out of the range allowed by the internal format used for the palette indices. count is silently clamped so that all modified entries all within the legal range. format and type can be any of the values legal for ColorTableEXT. The data is treated as a 1D texture just as in ColorTableEXT.

In the 'Texture State and Proxy State' section the sentence fragment beginning 'six integer values describing the resolutions...' should be changed to refer to seven integer values, with the seventh being the index resolution.

Palette data should be added in as a third category of texture state.

After the discussion of properties, the following should be added:

Next there is the texture palette. All textures have a palette, even if their internal format is not color index. A texture's palette is initially one RGBA element with all four components set to 1.0.

The sentence mentioning that proxies do not have image data or properties should be extended with 'or palettes.'

The sentence beginning 'If the texture array is too large' describing the effects of proxy failure should change to read:

If the implementation is unable to handle the texture image data the proxy width, height, border width and component resolutions are set to zero. This situation can occur when the texture array is too large or an unsupported paletted format was requested.

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

None

Additions to Chapter 5 of the GL Specification (Special Functions)

Section 5.4, 'Display Lists' is modified as follows:

Include PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_3D, and PROXY_TEXTURE_CUBE_MAP_ARB in the list of tokens for which ColorTableEXT is executed immediately.

Additions to Chapter 6 of the GL Specification (State and State Requests)

In the section on GetTexImage, the sentence saying 'The components are assigned among R, G, B and A according to' should be changed to be

If the internal format of the texture is not a color index format then the components are assigned among R, G, B, and A according to Table 6.1. Specifying COLOR_INDEX for format in this case will generate the error INVALID_ENUM. If the internal format of the texture is color index then the components are handled in one of two ways depending on the value of format. If format is not COLOR_INDEX, the texture's indices are passed through the texture's palette and the resulting components are assigned among R, G, B, and A according to Table 6.1. If format is COLOR_INDEX then the data is treated as single components and the palette indices are returned. Components are taken starting...

Following the GetTexImage section there should be a new section:

GetColorTableEXT is used to get the current texture palette.

```
void GetColorTableEXT(enum target, enum format, enum type, void *data);
```

GetColorTableEXT retrieves the texture palette of the texture given by target. target can be any of the non-proxy targets valid for ColorTableEXT. format and type are interpreted just as for ColorTableEXT. All textures have a palette by default so GetColorTableEXT will always be able to return data even if the internal format of the texture is not a color index format.

Palette parameters can be retrieved using

```
void GetColorTableParameterivEXT(enum target, enum pname, int *params);
void GetColorTableParameterfvEXT(enum target, enum pname, float *params);
```

target specifies the texture being queried and pname controls which parameter value is returned. Data is returned in the memory pointed to by params.

Querying COLOR_TABLE_FORMAT_EXT returns the internal format requested by the most recent ColorTableEXT call or the default. COLOR_TABLE_WIDTH_EXT returns the width of the current palette. COLOR_TABLE_RED_SIZE_EXT, COLOR_TABLE_GREEN_SIZE_EXT, COLOR_TABLE_BLUE_SIZE_EXT and COLOR_TABLE_ALPHA_SIZE_EXT return the actual size of the components used to store the palette data internally, not the size requested when the palette was defined.

    Table 6.11, "Texture Objects" should have a line appended for
    TEXTURE_INDEX_SIZE_EXT:

```
TEXTURE_INDEX_SIZE_EXT  n x Z+  GetTexLevelParameter 0 xD texture image i's index resolution 3.8 -
```

New State

    In table 6.16, Texture Objects, p. 224, add the following:

Get Value	Type	Get Command	Initial Value	Description	Sec.	Attribute
TEXTURE_1D	I	GetColorTableEXT	empty	1D palette	3.8	-
TEXTURE_2D	I	GetColorTableEXT	empty	2D palette	3.8	-
TEXTURE_3D	I	GetColorTableEXT	empty	3D palette	3.8	-
TEXTURE_CUBE_MAP	I	GetColorTableEXT	empty	cube map palette	3.8	-
COLOR_TABLE_FORMAT_EXT	2x4xZn	GetColorTableParameterivEXT	RGBA	paletted texture formats	3.8	-
COLOR_TABLE_WIDTH_EXT	2x4xZ+	GetColorTableParameteriv	0	paletted texture width	3.8	-
COLOR_TABLE_x_SIZE_EXT	6x2x4xZ+	GetColorTableParameteriv	0	paletted texture component sizes	3.8	-
TEXTURE_INDEX_SIZE_EXT	nxZ+	GetTexLevelParameter	0	texture image's index resolution	3.8	-

New Implementation Dependent State

    None

Revision History

Original draft, revision 0.5, December 20, 1995 (drewb) Created

Minor revisions and clarifications, revision 0.6, January 2, 1996 (drewb)
    Replaced all request-for-comment blocks with final text
    based on implementation.

Minor revisions and clarifications, revision 0.7, Feburary 5, 1996 (drewb)
    Specified the state of the palette color information
    when existing data is replaced by new data.

    Clarified behavior of TexPalette on inconsistent textures.

Major changes due to ARB review, revision 0.8, March 1, 1996 (drewb)
    Switched from using TexPaletteEXT and GetTexPaletteEXT
    to using SGI's ColorTableEXT routines. Added ColorSubTableEXT so
    equivalent functionality is available.

    Allowed proxies in all targets.

    Changed PALETTE?_EXT values to COLOR_INDEX?_EXT. Added
    support for one and two bit palettes. Removed PALETTE_INDEX_EXT in
    favor of COLOR_INDEX.

    Decoupled palette size from texture data type. Palette
    size is controlled only by ColorTableEXT.

Changes due to ARB review, revision 1.0, May 23, 1997 (drewb)
    Mentioned texture3D.

    Defined TEXTURE_INDEX_SIZE_EXT.

```
        Allowed implementations to return an index size of zero to indicate
        no support for a particular format.

        Allowed usage of GL_COLOR_INDEX as a generic format in
        proxy queries for determining an optimal index size for a particular
        texture.

        Disallowed CopyTexImage and CopyTexSubImage to paletted
        formats.

        Deleted mention of index transfer operations during GetTexImage with
        paletted formats.

    Changes due to ARB_texture_cube_map, revision 1.1, June 27, 2002.
        Add language to section 5.4 about proxy texture tokens for ColorTable
        executing immediately.

        Document ARB_texture_cube_map interactions.

        Document texture target usage for ColorTable API.

        Add "New State" section with table and "New Implementation Dependent
        State" sections.

    Changes, revision 1.4, March 24, 2004.
        Document vendor support for this extension; note that future NVIDIA
        GPU designs will not support this extension.
```

Name

    EXT_pixel_buffer_object

Name Strings

    GL_EXT_pixel_buffer_object

Status

    Implemented by NVIDIA drivers (Release 55).

IP Status

    Unknown.

Version

    NVIDIA Date: March 29, 2004 (version 1.0)

Number

    302

Status

    NVIDIA Release 55 (early 2004) drivers support this extension.

Dependencies

    Written based on the wording of the OpenGL 1.5 specification.

    GL_NV_pixel_data_range affects the definition of this extension.

Overview

    This extension expands on the interface provided by buffer objects.
    It is intended to permit buffer objects to be used not only with
    vertex array data, but also with pixel data.
    Buffer objects were promoted from the ARB_vertex_buffer_object
    extension in OpenGL 1.5.

    Recall that buffer objects conceptually are nothing more than arrays
    of bytes, just like any chunk of memory. Buffer objects allow GL
    commands to source data from a buffer object by binding the buffer
    object to a given target and then overloading a certain set of GL
    commands' pointer arguments to refer to offsets inside the buffer,
    rather than pointers to user memory. An offset is encoded in a
    pointer by adding the offset to a null pointer.

    This extension does not add any new functionality to buffer
    objects themselves. It simply adds two new targets to which buffer
    objects can be bound: PIXEL_PACK_BUFFER and PIXEL_UNPACK_BUFFER.
    When a buffer object is bound to the PIXEL_PACK_BUFFER target,
    commands such as ReadPixels write their data into a buffer object.
    When a buffer object is bound to the PIXEL_UNPACK_BUFFER target,
    commands such as DrawPixels read their data from a buffer object.

There are a wide variety of applications for such functionality.
Some of the most interesting ones are:

- "Render to vertex array." The application can use a fragment program to render some image into one of its buffers, then read this image out into a buffer object via ReadPixels. Then, it can use this buffer object as a source of vertex data.

- Streaming textures. If the application uses MapBuffer/UnmapBuffer to write its data for TexSubImage into a buffer object, at least one of the data copies usually required to download a texture can be eliminated, significantly increasing texture download performance.

- Asynchronous ReadPixels. If an application needs to read back a number of images and process them with the CPU, the existing GL interface makes it nearly impossible to pipeline this operation. The driver will typically send the hardware a readback command when ReadPixels is called, and then wait for all of the data to be available before returning control to the application. Then, the application can either process the data immediately or call ReadPixels again; in neither case will the readback overlap with the processing. If the application issues several readbacks into several buffer objects, however, and then maps each one to process its data, then the readbacks can proceed in parallel with the data processing.

Issues

How does this extension relate to ARB_vertex_buffer_object?

It builds on the ARB_vertex_buffer_object framework by adding two new targets that buffers can be bound to.

How does this extension relate to NV_pixel_data_range?

This extension relates to NV_pixel_data_range in the same way that ARB_vertex_buffer_object relates to NV_vertex_array_range. To paraphrase the ARB_vertex_buffer_object spec, here are the main differences:

- Applications are no longer responsible for memory management and synchronization.

- Applications may still access high-performance memory directly, but this is optional, and such access is more restricted.

- Buffer changes (BindBuffer) are generally expected to be very lightweight, rather than extremely heavyweight (PixelDataRangeNV).

- A platform-specific allocator such as wgl/glXAllocateMemoryNV is no longer required.

Can a given buffer be used for both vertex and pixel data?

RESOLVED: YES. All buffers can be used with all buffer bindings, in whatever combinations the application finds useful. Consider yourself warned, however, by the following issue.

May implementations make use of the target as a hint to select an appropriate memory space for the buffer?

RESOLVED: YES, as long as such behavior is transparent to the application. Some implementations may choose, for example, that they would rather stream vertex data from write-combined system memory, element (or index) data from video memory, and pixel data from video memory.

In fact, one can imagine arbitrarily complicated heuristics for selecting the memory space, based on factors such as the target, the "usage" argument, and the application's observed behavior.

While it is entirely legal to create a buffer object by binding it to ARRAY_BUFFER and loading it with data, then using it with the PIXEL_UNPACK_BUFFER_EXT or PIXEL_PACK_BUFFER_EXT binding, such behavior is liable to confuse the driver and may hurt performance. If the driver implemented the hypothetical heuristic described earlier, such a buffer might have already been located in write-combined system memory, and so the driver would have to choose between two bad options: relocate the buffer into video memory, or accept lower performance caused by streaming pixel data from slower system memory.

Should all pixel path commands be supported, or just a subset of them?

RESOLVED: ALL. While there is little reason to believe that, say, ConvolutionFilter2D would benefit from this extension, there is no reason _not_ to support it. The full list of commands affected by this extension is listed in the spec.

Should PixelMap and GetPixelMap be supported?

RESOLVED: YES. They're not really pixel path operations, but, again, there is no good reason to omit operations, and they _are_ operations that pass around big chunks of pixel-related data. If we support PolygonStipple, surely we should support this.

How does the buffer binding state push/pop?

RESOLVED: As part of the pixel store client state. This is analogous to how the vertex buffer object bindings pushed/popped as part of the vertex array client state.

Should NV_pixel_data_range (PDR) be used concurrently with pixel buffer objects ?

RESOLVED: NO. While it would be possible to allocate a memory range for PDR, using a pointer into this memory range with one of the commands affected by EXT_pixel_buffer_object will not work if a pixel buffer object other than zero is bound to the buffer binding point affecting the command. Pixel buffer objects always have higher precedence than PDR.

Do the null pointer rules for glTexImage1D, glTexImage2D and glTexImage3D for allocating textures with undefined content also apply when a non-zero buffer object is bound to PIXEL_UNPACK_BUFFER_BINDING_EXT ?

RESOLVED: NO. The null pointer is interpreted as a non-zero pointer to the data storage whose contents may be still undefined. This data will be used to create the texture array. If the null pointer rule is required, no non-zero buffer object should be bound to PIXEL_UNPACK_BUFFER_BINDING_EXT.

New Procedures and Functions

None.

New Tokens

Accepted by the <target> parameters of BindBuffer, BufferData, BufferSubData, MapBuffer, UnmapBuffer, GetBufferSubData, GetBufferParameteriv, and GetBufferPointerv:

PIXEL_PACK_BUFFER_EXT	0x88EB
PIXEL_UNPACK_BUFFER_EXT	0x88EC

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

PIXEL_PACK_BUFFER_BINDING_EXT	0x88ED
PIXEL_UNPACK_BUFFER_BINDING_EXT	0x88EF

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

None

Additions to Chapter 3 of the 1.2.1 Specification (Rasterization)

Additions to subsection 3.8.1 of the 1.2.1 Specification (Texture Image Specification)

The extension EXT_pixel_buffer_object makes an exception to this rule of passing a null pointer to glTexImage1D, glTexImage2D and glTexImage3D. If PIXEL_UNPACK_BUFFER_BINDING_EXT is non-zero and a null pointer is passed to these functions, the texture array is created and the image contents are sourced from the data store of the bound buffer object.

Additions to Chapter 4 of the 1.2.1 Specification (Per-Fragment Operations and the Frame Buffer)

Added a subsection 4.3.5 (Pixel Buffer Object unpack operation) in section 4.3 (Drawing, Reading and copying Pixels)

The extension EXT_pixel_buffer_object affects the operation of several OpenGL commands described in section 3.6 (Pixel Rectangles), section 3.7 (Bitmaps), and section 3.8 (Texturing).

In unextended OpenGL 1.3 with ARB_imaging support, the commands glBitmap, glColorSubTable, glColorTable, glCompressedTexImage1D, glCompressedTexImage2D, glCompressedTexImage3D, glCompressedTexSubImage1D, glCompressedTexSubImage2D, glCompressedTexSubImage3D, glConvolutionFilter1D, glConvolutionFilter2D, glDrawPixels, glPixelMapfv, glPixelMapuiv, glPixelMapusv, glPolygonStipple, glSeparableFilter2D, glTexImage1D, glTexImage2D, glTexImage3D, glTexSubImage1D, glTexSubImage2D and glTexSubImage3D operate as previously defined, except that pixel data is sourced from a buffer object's data store if PIXEL_UNPACK_BUFFER_BINDING_EXT is non-zero. When the data is sourced from a buffer object, the pointer value passed in as an argument to the command is used to compute an offset, in basic machine units, into the data store of the buffer object. This offset is computed by subtracting a null pointer from the pointer value, where both pointers are treated as pointers to basic machine units.

Additions to Chapter 5 of the 1.2.1 Specification (Special Functions)

None

Additions to Chapter 6 of the 1.2.1 Specification (State and State Requests)

Additions to subsection 6.1.13 (Buffer Object Queries) in chapter 6

In unextended OpenGL 1.5 with ARB_imaging support, the commands glGetColorTable, glGetCompressedTexImage, glGetConvolutionFilter, glGetHistogram, glGetMinmax, glGetPixelMapfv, glGetPixelMapuiv, glGetPixelMapusv, glGetPolygonStipple, glGetSeparableFilter, glGetTexImage and glReadPixels operate as previously defined, except that pixel data is stored in a buffer object's data store if PIXEL_PACK_BUFFER_BINDING_EXT is non-zero. When a buffer object is the target of the pixel data, the target pointer value passed in as an argument to the command is used to compute an offset, in basic machine units, into the data store of the buffer object. This offset is computed by subtracting a null pointer from the pointer value, where both pointers are treated as pointers to basic machine units.

Errors

None

New State

(table 6.20, Pixels, p. 235)

```
Get Value                        Type  Get Command  Initial Value  Sec     Attribute
---------                        ----  -----------  -------------  ---     ---------
PIXEL_PACK_BUFFER_BINDING_EXT    Z+    GetIntegerv  0              4.3.5   pixel-store
PIXEL_UNPACK_BUFFER_BINDING_EXT  Z+    GetIntegerv  0              6.1.13  pixel-store
```

New Implementation Dependent State

    (none)

Usage Examples

    Convenient macro definition for specifying buffer offsets:

```
        #define BUFFER_OFFSET(i) ((char *)NULL + (i))
```

    Example 1: Render to vertex array

```
        // create a buffer object for a number of vertices consisting of
        // 4 float values per vertex
        GenBuffers(1, vertexBuffer);
        BindBuffer(PIXEL_PACK_BUFFER_EXT, vertexBuffer);
        BufferData(PIXEL_PACK_BUFFER_EXT, numberVertices*4, NULL, DYNAMIC_DRAW);

        // render vertex data into framebuffer using a fragment program
        BindProgramARB(FRAGMENT_PROGRAM_ARB, fragmentProgram);
        DrawBuffer(GL_BACK);
        renderVertexData();
        BindProgramARB(FRAGMENT_PROGRAM_ARB, 0);

        // read the vertex data back from framebuffer
        ReadBuffer(GL_BACK);
        ReadPixels(0, 0, numberVertices*4, height/2,
            GL_BGRA, GL_FLOAT, BUFFER_OFFSET(0));

        // change the binding point of the buffer object to
        // the vertex array binding point
        BindBuffer(GL_ARRAY_BUFFER, vertexBuffer);

        EnableClientState(VERTEX_ARRAY);
        VertexPointer(4, FLOAT, 0, BUFFER_OFFSET(0));
        DrawArrays(TRIANGLE_STRIP, 0, numberVertices);
```

Example 2: Streaming textures

streaming textures using NV_pixel_data_range

```
    void *pdrMemory, *texData;

    pdrMemory = AllocateMemoryNV(texsize, 0.0, 1.0, 1.0);

    PixelDataRangeNV(GL_WRITE_PIXEL_DATA_RANGE_NV, texsize, pdrMemory);

    EnableClientState(GL_WRITE_PIXEL_DATA_RANGE_NV);

    // setup texture environment
    ...

    texData = getNextImage();

    while (texData) {

        memcpy(pdrMemory, texData, texsize);

        FlushPixelDataRangeNV(GL_WRITE_PIXEL_DATA_RANGE_NV);

        TexSubImage2D(GL_TEXTURE_2D, 0, 0, 0,
            texWidth, texHeight, GL_BGRA, GL_UNSIGNED_BYTE, pdrMemory);

        // draw textured geometry
        Begin(GL_QUADS);
        ...
        End();

        texData = getNextImage();
    }

    DisableClientState(GL_WRITE_PIXEL_DATA_RANGE_NV);

    FreeMemoryNV(pdrMemory);
streaming textures using EXT_pixel_buffer_object:

    void *pboMemory, *texData;

    // create and bind texture image buffer object
    GenBuffers(1, &texBuffer);
    BindBuffer(PIXEL_UNPACK_BUFFER_EXT, texBuffer);
    BufferData(PIXEL_UNPACK_BUFFER_EXT, texSize, NULL, STREAM_DRAW);

    texData = getNextImage();

    while (texData) {

        // map the texture image buffer
        pboMemory = MapBuffer(PIXEL_UNPACK_BUFFER_EXT, WRITE_ONLY);

        // modify (sub-)buffer data
        memcpy(pboMemory, texData, texsize);

        // unmap the texture image buffer
        if (!UnmapBuffer(PIXEL_UNPACK_BUFFER_EXT)) {
            // Handle error case
        }

        // update (sub-)teximage from texture image buffer
        TexSubImage2D(GL_TEXTURE_2D, 0, 0, 0, texWidth, texHeight,
                      GL_BGRA, GL_UNSIGNED_BYTE, BUFFER_OFFSET(0));

        // draw textured geometry
        Begin(GL_QUADS);
        ...
        End();

        texData = getNextImage();
    }

    BindBuffer(PIXEL_UNPACK_BUFFER_EXT, 0);
```

Example 3: Asynchronous ReadPixels

traditional ReadPixels

```
    unsigned int readBuffer[imagewidth*imageheight*4];

    // render to framebuffer
    DrawBuffer(GL_BACK);
    renderScene()

    // read image from framebuffer
    ReadBuffer(GL_BACK);
    ReadPixels();

    // process image when ReadPixels returns after reading the whole buffer
    processImage(readBuffer);
```

asynchronous ReadPixels

```
    GenBuffers(2, imageBuffers);

    BindBuffer(PIXEL_PACK_BUFFER_EXT, imageBuffers[0]);
    BufferData(PIXEL_PACK_BUFFER_EXT, imageSize / 2, NULL, STATIC_READ);

    BindBuffer(PIXEL_PACK_BUFFER_EXT, imageBuffers[1]);
    BufferData(PIXEL_PACK_BUFFER_EXT, imageSize / 2, NULL, STATIC_READ);

    // render to framebuffer
    DrawBuffer(GL_BACK);
    renderScene();

    // Bind two different buffer objects and start the ReadPixels
    // asynchronously. Each call will return directly after starting the
    // DMA transfer.
    BindBuffer(PIXEL_PACK_BUFFER_EXT, imageBuffers[0]);
    ReadPixels(0, 0, width, height/2,
        GL_BGRA, GL_UNSIGNED_BYTE, BUFFER_OFFSET(0));

    BindBuffer(PIXEL_PACK_BUFFER_EXT, imageBuffers[1]);
    ReadPixels(0, height/2, width, height/2, GL_BGRA, GL_UNSIGNED_BYTE,
               BUFFER_OFFSET(0));

    // process partial images
    pboMemory1 = MapBuffer(PIXEL_PACK_BUFFER_EXT, READ_ONLY);
    processImage(pboMemory1);
    pboMemory2 = MapBuffer(PIXEL_PACK_BUFFER_EXT, READ_ONLY);
    processImage(pboMemory2);

    // unmap the image buffers
    BindBuffer(PIXEL_PACK_BUFFER_EXT, imageBuffers[0]);
    if (!UnmapBuffer(PIXEL_PACK_BUFFER_EXT)) {
        // Handle error case
    }
    BindBuffer(PIXEL_PACK_BUFFER_EXT, imageBuffers[1]);
    if (!UnmapBuffer(PIXEL_PACK_BUFFER_EXT)) {
        // Handle error case
    }
```

Dependencies

SGIS_multisample affects the definition of this extension.

Overview

This extension supports additional geometric characteristics of points. It can be used to render particles or tiny light sources, commonly referred as "Light points".

The raster brightness of a point is a function of the point area, point color, point transparency, and the response of the display's electron gun and phosphor. The point area and the point transparency are derived from the point size, currently provided with the <size> parameter of glPointSize.

The primary motivation is to allow the size of a point to be affected by distance attenuation. When distance attenuation has an effect, the final point size decreases as the distance of the point from the eye increases.

The secondary motivation is a mean to control the mapping from the point size to the raster point area and point transparency. This is done in order to increase the dynamic range of the raster brightness of points. In other words, the alpha component of a point may be decreased (and its transparency increased) as its area shrinks below a defined threshold.

This extension defines a derived point size to be closely related to point brightness. The brightness of a point is given by:

```
                        1
    dist_atten(d) = -------------------
                    a + b * d + c * d^2

    brightness(Pe) = Brightness * dist_atten(|Pe|)
```

where 'Pe' is the point in eye coordinates, and 'Brightness' is some initial value proportional to the square of the size provided with glPointSize. Here we simplify the raster brightness to be a function of the rasterized point area and point transparency.

```
                  brightness(Pe)                  brightness(Pe) >= Threshold_Area
    area(Pe) =
                  Threshold_Area                  Otherwise

    factor(Pe) = brightness(Pe)/Threshold_Area

    alpha(Pe) = Alpha * factor(Pe)
```

where 'Alpha' comes with the point color (possibly modified by lighting).

'Threshold_Area' above is in area units. Thus, it is proportional to the square of the threshold provided by the programmer through this extension.

The new point size derivation method applies to all points, while the threshold applies to multisample points only.

Issues

* Does point alpha modification affect the current color ?

  No.

* Do we need a special function glGetPointParameterfvEXT, or get by with glGetFloat ?

  No.

* If alpha is 0, then we could toss the point before it reaches the fragment stage.

  No. This can be achieved with enabling the alpha test with reference of 0 and function of LEQUAL.

* Do we need a disable for applying the threshold ? The default threshold value is 1.0. It is applied even if the point size is constant.

  If the default threshold is not overriden, the area of multisample points with provided constant size of less than 1.0, is mapped to 1.0, while the alpha component is modulated accordingly, to compensate for the larger area. For multisample points this is not a problem, as there are no relevant applications yet. As mentioned above, the threshold does not apply to alias or antialias points.

  The alternative is to have a disable of threshold application, and state that threshold (if not disabled) applies to non antialias points only (that is, alias and multisample points).

  The behavior without an enable/disable looks fine.

* Future extensions (to the extension)

  1. GL_POINT_FADE_ALPHA_CLAMP_EXT

  When the derived point size is larger than the threshold size defined by the GL_POINT_FADE_THRESHOLD_SIZE_EXT parameter, it might be desired to clamp the computed alpha to a minimum value, in order to keep the point visible. In this case the formula below change:

```
        factor = (derived_size/threshold)^2

                        factor                  clamp <= factor
        clamped_value =
                        clamp                   factor < clamp

                 1.0                            derived_size >= threshold
        alpha *=
                 clamped_value                  Otherwise

        where clamp is defined by the GL_POINT_FADE_ALPHA_CLAMP_EXT new
        parameter.
```

New Procedures and Functions

```
    void glPointParameterfEXT ( GLenum pname, GLfloat param );
    void glPointParameterfvEXT ( GLenum pname, GLfloat *params );
```

New Tokens

    Accepted by the <pname> parameter of glPointParameterfEXT, and the <pname>
    of glGet:

        GL_POINT_SIZE_MIN_EXT
        GL_POINT_SIZE_MAX_EXT
        GL_POINT_FADE_THRESHOLD_SIZE_EXT

    Accepted by the <pname> parameter of glPointParameterfvEXT, and the <pname>
    of glGet:

        GL_POINT_SIZE_MIN_EXT   0x8126
        GL_POINT_SIZE_MAX_EXT   0x8127
        GL_POINT_FADE_THRESHOLD_SIZE_EXT   0x8128
        GL_DISTANCE_ATTENUATION_EXT   0x8129

Additions to Chapter 2 of the 1.0 Specification (OpenGL Operation)

None

Additions to Chapter 3 of the 1.0 Specification (Rasterization)

All parameters of the glPointParameterfEXT and glPointParameterfvEXT functions set various values applied to point rendering. The derived point size is defined to be the <size> provided with glPointSize modulated with a distance attenuation factor.

The parameters GL_POINT_SIZE_MIN_EXT and GL_POINT_SIZE_MAX_EXT simply define an upper and lower bounds respectively on the derived point size.

The above parameters affect non multisample points as well as multisample points, while the GL_POINT_FADE_THRESHOLD_SIZE_EXT parameter, has no effect on non multisample points. If the derived point size is larger than the threshold size defined by the GL_POINT_FADE_THRESHOLD_SIZE_EXT parameter, the derived point size is used as the diameter of the rasterized point, and the alpha component is intact. Otherwise, the threshold size is set to be the diameter of the rasterized point, while the alpha component is

```
    modulated accordingly, to compensate for the larger area.

    The distance attenuation function coefficients, namely a, b, and c in:

                          1
        dist_atten(d) = -------------------
                        a + b * d + c * d^2

    are defined by the <pname> parameter GL_DISTANCE_ATTENUATION_EXT of the
    function glPointParameterfvEXT. By default a = 1, b = 0, and c = 0.

    Let 'size' be the point size provided with glPointSize,  let 'dist' be the
    distance of the point from the eye, and let 'threshold' be the threshold
    size defined by the GL_POINT_FADE_THRESHOLD_SIZE parameter of
    glPointParameterfEXT. The derived point size is given by:

        derived_size = size * sqrt(dist_atten(dist))

    Note that when default values are used, the above formula reduces to:

        derived_size = size

    the diameter of the rasterized point is given by:

                   derived_size                derived_size >= threshold
        diameter =
                   threshold                   Otherwise

    The alpha of a point is calculated to allow the fading of points instead of
    shrinking them past a defined threshold size. The alpha component of the
    rasterized point is given by:

                 1                             derived_size >= threshold
        alpha *=
                 (derived_size/threshold)^2    Otherwise

    The threshold defined by GL_POINT_FADE_THRESHOLD_SIZE_EXT is not clamped
    to the minimum and maximum point sizes.

    Points do not affect the current color.

    This extension doesn't change the feedback or selection behavior of points.

Overview

When normal rescaling is enabled a new operation is added to the transformation of the normal vector into eye coordinates. The normal vector is rescaled after it is multiplied by the inverse modelview matrix and before it is normalized.

The rescale factor is chosen so that in many cases normal vectors with unit length in object coordinates will not need to be normalized as they are transformed into eye coordinates.

New Procedures and Functions

None

New Tokens

Accepted by the <cap> parameter of Enable, Disable, and IsEnabled, and by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
    RESCALE_NORMAL_EXT                   0x803A
```

Additions to Chapter 2 of the 1.1 Specification (OpenGL Operation)

Section 2.10.3

Finally, we consider how the ModelView transformation state affects normals. Normals are of interest only in eye coordinates, so the rules governing their transformation to other coordinate systems are not examined.

Normals which have unit length when sent to the GL, have their length changed by the inverse of the scaling factor after transformation by the model-view inverse matrix when the model-view matrix represents a uniform scale. If rescaling is enabled, then normals specified with

```
    the Normal command are rescaled after transformation by the ModelView
    Inverse.

    Normals sent to the GL may or may not have unit length. In addition,
    the length of the normals after transformation might be altered due
    to transformation by the model-view inverse matrix. If normalization
    is enabled, then normals specified with the Normal3 command are
    normalized after transformation by the model-view inverse matrix and
    after rescaling if rescaling is enabled.  Normalization and rescaling
    are controlled with

        void Enable( enum target);

    and

        void Disable( enum target);

    with target equal to NORMALIZE or RESCALE_NORMAL. This requires two
    bits of state.  The initial state is for normals not to be normalized or
    rescaled.
    .
    .
    .

    Therefore, if the modelview matrix is M, then the transformed plane equation
    is

     (n_x' n_y' n_z' q') = ((n_x n_y n_z q) * (M^-1)),

    the rescaled normal is

     (n_x" n_y" n_z")  = f * (n_x' n_y' n_z'),

    and the fully transformed normal is

              1                                  (n_x")
          ____________                           (n_y")             (2.1)
        __________________________________       (n_z")
       V (n_x")^2 + (n_y")^2 + (n_z")^2

     If rescaling is disabled then f is 1, otherwise f is computed
     as follows:

     Let m_ij denote the matrix element in row i and column j of M^-1,
     numbering the topmost row of the matrix as row 1, and the leftmost
     column as column 1. Then

                           1
                       __________
            f =   ________________________________
                 V (m_31)^2 + (m_32)^2 + (m_33)^2

     Alternatively, an implementation my chose to normalize the normal
     instead of rescaling the normal. Then
```

$$f = \frac{1}{\sqrt{(n\_x')^2 + (n\_y')^2 + (n\_z')^2}}$$

If normalization is disabled, then the square root in equation 2.1 is replaced with 1, otherwise . . . .

    GL_EXT_secondary_color

Version

    NVIDIA Date: February 22, 2000
    $Date: 1999/06/21 19:57:47 $ $Revision: 1.8 $

Number

    145

Dependencies

    Either EXT_separate_specular_color or OpenGL 1.2 is required, to specify
    the "Color Sum" stage and other handling of the secondary color. This is
    written against the 1.2 specification (available from www.opengl.org).

Overview

    This extension allows specifying the RGB components of the secondary
    color used in the Color Sum stage, instead of using the default
    (0,0,0,0) color. It applies only in RGBA mode and when LIGHTING is
    disabled.

Issues

  * Can we use the secondary alpha as an explicit fog weighting factor?

        ISVs prefer a separate interface (see GL_EXT_fog_coord). The current
        interface specifies only the RGB elements, leaving the option of a
        separate extension for SecondaryColor4() entry points open (thus
        the apparently useless ARRAY_SIZE state entry).

        There is an unpleasant asymmetry with Color3() - one assumes A =
        1.0, the other assumes A = 0.0 - but this appears unavoidable given
        the 1.2 color sum specification language. Alternatively, the color
        sum language could be rewritten to not sum secondary A.

  * What about multiple "color iterators" for use with aggrandized
    multitexture implementations?

        We may need this eventually, but the secondary color is well defined
        and a more generic interface doesn't seem justified now.

  * Interleaved array formats?

        No. The multiplicative explosion of formats is too great.
  * Do we want to be able to query the secondary color value? How does it
    interact with lighting?

        The secondary color is not part of the GL state in the
        separate_specular_color extension that went into OpenGL 1.2. There,
        it can't be queried or obtained via feedback.

        The secondary_color extension is slightly more general-purpose, so
        the secondary color is explicitly in the GL state and can be queried
        - but it's still somewhat limited and can't be obtained via
        feedback, for example.
```

New Procedures and Functions

```
    void SecondaryColor3[bsifd ubusui]EXT(T components)
    void SecondaryColor3[bsifd ubusui]vEXT(T components)
    void SecondaryColorPointerEXT(int size, enum type, sizei stride,
                                  void *pointer)
```

New Tokens

```
    Accepted by the <cap> parameter of Enable, Disable, and IsEnabled,
    and by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv,
    and GetDoublev:

        COLOR_SUM_EXT                       0x8458

    Accepted by the <pname> parameter of GetBooleanv, GetIntegerv,
    GetFloatv, and GetDoublev:

        CURRENT_SECONDARY_COLOR_EXT         0x8459
        SECONDARY_COLOR_ARRAY_SIZE_EXT      0x845A
        SECONDARY_COLOR_ARRAY_TYPE_EXT      0x845B
        SECONDARY_COLOR_ARRAY_STRIDE_EXT    0x845C

    Accepted by the <pname> parameter of GetPointerv:

        SECONDARY_COLOR_ARRAY_POINTER_EXT   0x845D

    Accepted by the <array> parameter of EnableClientState and
    DisableClientState:

        SECONDARY_COLOR_ARRAY_EXT           0x845E
```

Additions to Chapter 2 of the 1.2 Draft Specification (OpenGL Operation)

```
  These changes describe a new current state type, the secondary color, and
  the commands to specify it:

  - (2.6, p. 12) Second paragraph changed to:

        "Each vertex is specified with two, three, or four coordinates. In
        addition, a current normal, current texture coordinates, current
        color, and current secondary color may be used in processing each
        vertex."
```

```
    Third paragraph, second sentence changed to:

        "These associated colors are either based on the current color and
        current secondary color, or produced by lighting, depending on
        whether or not lighting is enabled."

  - 2.6.3, p. 19) First paragraph changed to

        "The only GL commands that are allowed within any Begin/End pairs
        are the commands for specifying vertex coordinates, vertex colors,
        normal coordinates, and texture coordinates (Vertex, Color,
        SecondaryColorEXT, Index, Normal, TexCoord)..."

  - (2.7, p. 20) Starting with the fourth paragraph, change to:

        "Finally, there are several ways to set the current color and
        secondary color. The GL stores a current single-valued color index
        as well as a current four-valued RGBA color and secondary color.
        Either the index or the color and secondary color are significant
        depending as the GL is in color index mode or RGBA mode. The mode
        selection is made when the GL is initialized.

        The commands to set RGBA colors and secondary colors are:

            void Color[34][bsifd ubusui](T components)
            void Color[34][bsifd ubusui]v(T components)
            void SecondaryColor3[bsifd ubusui]EXT(T components)
            void SecondaryColor3[bsifd ubusui]vEXT(T components)

        The color command has two major variants: Color3 and Color4. The
        four value versions set all four values. The three value versions
        set R, G, and B to the provided values; A is set to 1.0. (The
        conversion of integer color components (R, G, B, and A) to
        floating-point values is discussed in section 2.13.)

        The secondary color command has only the three value versions.
        Secondary A is always set to 0.0.

        Versions of the Color and SecondaryColorEXT commands that take
        floating-point values accept values nominally between 0.0 and
        1.0...."

    The last paragraph is changed to read:

        "The state required to support vertex specification consists of four
        floating-point numbers to store the current texture coordinates s,
        t, r, and q, four floating-point values to store the current RGBA
        color, four floating-point values to store the current RGBA
        secondary color, and one floating-point value to store the current
        color index. There is no notion of a current vertex, so no state is
        devoted to vertex coordinates. The initial values of s, t, and r of
        the current texture coordinates are zero; the initial value of q is
        one. The initial current normal has coordinates (0,0,1). The initial
        RGBA color is (R,G,B,A) = (1,1,1,1). The initial RGBA secondary
        color is (R,G,B,A) = (0,0,0,0). The initial color index is 1."
  - (2.8, p. 21) Added secondary color command for vertex arrays:

    Change first paragraph to read:

        "The vertex specification commands described in section 2.7 accept
        data in almost any format, but their use requires many command
        executions to specify even simple geometry. Vertex data may also be
        placed into arrays that are stored in the client's address space.
        Blocks of data in these arrays may then be used to specify multiple
        geometric primitives through the execution of a single GL command.
        The client may specify up to seven arrays: one each to store edge
        flags, texture coordinates, colors, secondary colors, color indices,
        normals, and vertices. The commands"

    Add to functions listed following first paragraph:

        void SecondaryColorPointerEXT(int size, enum type, sizei stride,
                                      void *pointer)

    Add to table 2.4 (p. 22):

        Command                     Sizes   Types
        -------                     -----   -----
        SecondaryColorPointerEXT    3       byte,ubyte,short,ushort,int,uint,
                                            float,double

    Starting with the second paragraph on p. 23, change to add
    SECONDARY_COLOR_ARRAY_EXT:

        "An individual array is enabled or disabled by calling one of

            void EnableClientState(enum array)
            void DisableClientState(enum array)

        with array set to EDGE_FLAG_ARRAY, TEXTURE_COORD_ARRAY, COLOR_ARRAY,
        SECONDARY_COLOR_ARRAY_EXT, INDEX_ARRAY, NORMAL_ARRAY, or
        VERTEX_ARRAY, for the edge flag, texture coordinate, color,
        secondary color, color index, normal, or vertex array, respectively.

        The ith element of every enabled array is transferred to the GL by
        calling

            void ArrayElement(int i)

        For each enabled array, it is as though the corresponding command
        from section 2.7 or section 2.6.2 were called with a pointer to
        element i. For the vertex array, the corresponding command is
        Vertex<size><type>v, where <size> is one of [2,3,4], and <type> is
        one of [s,i,f,d], corresponding to array types short, int, float,
        and double respectively. The corresponding commands for the edge
        flag, texture coordinate, color, secondary color, color index, and
        normal arrays are EdgeFlagv, TexCoord<size><type>v,
        Color<size><type>v, SecondaryColor3<type>vEXT, Index<type>v, and
        Normal<type>v, respectively..."
    Change pseudocode on p. 27 to disable secondary color array for
    canned interleaved array formats. After the lines

            DisableClientState(EDGE_FLAG_ARRAY);
            DisableClientState(INDEX_ARRAY);

        insert the line

            DisableClientState(SECONDARY_COLOR_ARRAY_EXT);

    Substitute "seven" for every occurence of "six" in the final paragraph
    on p. 27.

  - (2.12, p. 41) Add secondary color to the current rasterpos state.

    Change the last paragraph to read

        "The current raster position requires five single-precision
        floating-point values for its x_w, y_w, and z_w window coordinates,
        its w_c clip coordinate, and its eye coordinate distance, a single
        valid bit, a color (RGBA color, RGBA secondary color, and color
        index), and texture coordinates for associated data. In the initial
        state, the coordinates and texture coordinates are both $(0,0,0,1)$,
        the eye coordinate distance is 0, the valid bit is set, the
        associated RGBA color is $(1,1,1,1)$, the associated RGBA secondary
        color is $(0,0,0,0)$, and the associated color index color is 1. In
        RGBA mode, the associated color index always has its initial value;
        in color index mode, the RGBA color and and secondary color always
        maintain their initial values."

  - (2.13, p. 43) Change second paragraph to acknowledge two colors when
    lighting is disabled:

        "Next, lighting, if enabled, produces either a color index or
        primary and secondary colors. If lighting is disabled, the current
        color index or current color (primary color) and current secondary
        color are used in further processing. After lighting, RGBA colors
        are clamped..."

  - (Figure 2.8, p. 42) Change to show primary and secondary RGBA colors in
    both lit and unlit paths.

  - (2.13.1, p. 44) Change so that the second paragraph starts:

    "Lighting may be in one of two states:

     1. Lighting Off. In this state, the current color and current secondary
        color are assigned to the vertex primary color and vertex secondary
        color, respectively.

     2. ..."
```

- (2.13.1, p. 48) Change the sentence following equation 2.5 (for spot_i) so that color sum is implicitly enabled when SEPARATE_SPECULAR_COLOR is set:

  "All computations are carried out in eye coordinates. When c_es = SEPARATE_SPECULAR_COLOR, it is as if color sum (see section 3.9) were enabled, regardless of the value of COLOR_SUM_EXT."

- (3.9, p. 136) Change the first paragraph to read

  "After texturing, a fragment has two RGBA colors: a primary color c_pri (which texturing, if enabled, may have modified) and a secondary color c_sec.

  If color sum is enabled, the components of these two colors are summed to produce a single post-texturing RGBA color c (the A component of the secondary color is always 0). The components of c are then clamped to the range [0,1]. If color sum is disabled, then c_pri is assigned to the post texturing color. Color sum is enabled or disabled using the generic Enable and Disable commands, respectively, with the symbolic constant COLOR_SUM_EXT.

  The state required is a single bit indicating whether color sum is enabled or disabled. In the initial state, color sum is disabled."

Overview

This extension adds a second color to rasterization when lighting is enabled. Its purpose is to produce textured objects with specular highlights which are the color of the lights. It applies only to rgba lighting.

The two colors are computed at the vertexes. They are both clamped, flat-shaded, clipped, and converted to fixed-point just like the current rgba color (see Figure 2.8). Rasterization interpolates both colors to fragments. If texture is enabled, the first (or primary) color is the input to the texture environment; the fragment color is the sum of the second color and the color resulting from texture application. If texture is not enabled, the fragment color is the sum of the two colors.

A new control to LightModel*, LIGHT_MODEL_COLOR_CONTROL_EXT, manages the values of the two colors. It takes values: SINGLE_COLOR_EXT, a compatibility mode, and SEPARATE_SPECULAR_COLOR_EXT, the object of this extension. In single color mode, the primary color is the current final color and the secondary color is 0.0. In separate specular mode, the primary color is the sum of the ambient, diffuse, and emissive terms of final color and the secondary color is the specular term.

There is much concern that this extension may not be compatible with the future direction of OpenGL with regards to better lighting and shading models. Until those impacts are resolved, serious consideration should be given before adding to the interface specified herein (for example, allowing the user to specify a second input color).

Issues

* Where is emissive included?

  RESOLVED - Emissive is included with the ambient and diffuse

```
    terms.  Grouping emissive with specular (the "proper" thing) could
    be implemented with a new value for the color control.

* Should there be two colors when not lighting or with index
  lighting?

    RESOLVED - The answer is probably yes--there should be two colors
    when lighting is disabled and there could be an incorporation of
    two colors with index lighting; but these are beyond the scope of
    this extension.  Further, attempts to accomplish these may not be
    compatible with the future direction of OpenGL with respect to
    high quality lighting and shading models.

  * What happens when texture is disabled?

    RESOLVED - The extension specifies to add the two colors when
    texture is disabled.  This is compatible with the philosophy of
    "if texture is disabled, this mode does not apply".
```

New Procedures and Functions

None.

New Tokens

Accepted by the <pname> parameter of LightModel*, and also by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
    LIGHT_MODEL_COLOR_CONTROL_EXT       0x81F8
```

Accepted by the <param> parameter of LightModel* when <pname> is LIGHT_MODEL_COLOR_CONTROL_EXT:

```
    SINGLE_COLOR_EXT                    0x81F9
    SEPARATE_SPECULAR_COLOR_EXT         0x81FA
```

Additions to Chapter 2 of the 1.0 Specification (OpenGL Operation)

```
  - (2.13, p. 40) Rework the second paragraph to acknowledge two
    colors:

    "Next, lighting, if enabled, produces either a color index or
    primary and secondary colors.  If lighting is disabled, the
    current color index or color is used in further processing (the
    current color is the primary color and the secondary color is 0).
    After lighting, colors are clamped..."

  - (Figure 2.8, p. 41) Change RGBA to primary RGBA and secondary RGB:

    Ideally, there might be an RGB2 underneath RGBA (both places).
    Alternatively, a note in the caption could clarify that RGBA
    referred to the primary RGBA and a secondary RGB.  (Speaking of
    the caption, the part about "m is the number of bits an R, G, B,
    or A component" could be removed as m doesn't appear in the
    diagram.)
```

```
- (2.13.1, p. 42) Rework the opening of this section to not imply a
  single color:

  In the first sentence, change "a color" to "colors".  Rephrase the
  itemization of the two lighting states to:

  "1. Lighting Off. In this state, the current color is assigned to
      the vertex primary color.  The vertex secondary color is 0.

   2. Lighting On.  In this state, the vertex primary and secondary
      colors are computed from the current lighting parameters."

- (Table 2.7, p.44) Add new entry (at the bottom):

  Parameter  Type  Default Value     Description
  ---------  ----  ----------------  ------------------------------
  c_es       enum  SINGLE_COLOR_EXT  controls computation of colors

- (p. 45, top of page) Rephrase the first line and equation:

  "Lighting produces two colors at a vertex: a primary color c_1 and
  a secondary color c_2.  The values of c_1 and c_2 depend on the
  light model color control, c_es (note: c_es should be in italics
  and c_1 and c_2 in bold, so this really won't be as confusing as
  it seems).  If c_es = SINGLE_COLOR_EXT, then the equations to
  compute c_1 and c_2 are (note: the equation for c_1 is the current
  equation for c):

    c_1 = e_cm
        + a_cm * a_cs
        + SUM(att_i * spot_i * (a_cm * a_cli
                               + dot(n, VP_pli) * d_cm * d_cli
                               + f_i * dot(n, h_i)^s_rm * s_cm * s_cli)
    c_2 = 0

  If c_es = SEPARATE_SPECULAR_COLOR_EXT, then:

    c_1 = e_cm
        + a_cm * a_cs
        + SUM (att_i * spot_i * (a_cm * a_cli
                                + (n dot VP_pli) * d_cm * d_cli)

    c_2 = SUM(att_i * spot_i * (f_i * (n dot h_i)^s_rm * s_cm * s_cli)

- (p. 45, second paragraph from bottom) Clarify that A is in the
  primary color:

  After the sentence "The value of A produced by lighting is the
  alpha value associated with d_cm", add "A is always associated
  with the primary color c_1; c_2 has no alpha component."

- (Table 2.8, p. 48) Add a new entry (at the bottom):

  Parameter  Name                          Number of values
  ---------  ----------------------------  ----------------
  c_es       LIGHT_MODEL_COLOR_CONTROL_EXT        1
```

- (2.13.6, p. 51) Clarify that both primary and secondary colors are clamped:

  Replace "RGBA" in the first line of the section with "both primary and secondary".

- (2.13.7, p. 52) Clarify what happens to primary and secondary colors when flat shading--reword the first paragraph:

  "A primitive may be flatshaded, meaning that all vertices of the primitive are assigned the same color index or primary and secondary colors. These come from the vertex that spawned the primitive. For a point, these are the colors associated with the point. For a line segment, they are the colors of the second (final) vertex of the segment. For a polygon, they come from a selected vertex depending on how the polygon was generated. Table 2.9 summarizes the possibilities."

- (2.13.8, p. 52) Rework to not imply a single color:

  In the second sentence, change "If the color is" to "Those" and ", it is" to "are". In the first sentence of the next paragraph, change "the color" to "two colors".

Additions to Chapter 3 of the 1.0 Specification (Rasterization)

- (Figure 3.1, p. 55) Add a box between texturing and fog called "color sum".

- (3.8, p. 85) In the first paragraph, second sentence, insert "primary" before RGBA. Insert after this sentence "Texturing does not affect the secondary color."

- (new section before 3.9) Insert new section titled "Color Sum":

  "At the beginning of this stage in RGBA mode, a fragment has two colors: a primary RGBA color (which texture, if enabled, may have modified) and a secondary RGB color. This stage sums the R, G, and B components of these two colors to produce a single RGBA color. If the resulting RGB values exceed 1.0, they are clamped to 1.0.

  In color index mode, a fragment only has a single color index and this stage does nothing."

Additions to Chapter 4 of the 1.0 Specification (Per-Fragment Operations and the Frame Buffer)

None.

Additions to Chapter 5 of the 1.0 Specification (Special Functions)

- (5.3, p. 137) Specify that feedback returns the primary color by changing the last sentence of the large paragraph in the middle of the page to:

    "The colors returned are the primary colors. These colors and the
    texture coordinates are those resulting from the clipping operations
    as described in section 2.13.8."

Additions to Chapter 6 of the 1.0 Specification (State and State Requests)

  - (Table 6.9, p. 157) Add:

```
    Get Value - LIGHT_MODEL_COLOR_CONTROL_EXT
    Type - Z2
    Get Cmnd - GetIntegerv
    Initial Value - SINGLE_COLOR_EXT
    Description - color control
    Sec. - (whatever it ends up as)
    Attribute - lighting
```

Additions to the GLX Specification

Dependencies

```
    OpenGL 1.1 is required.
    ARB_depth_texture is required.
    ARB_shadow is required.
    This extension is written against the OpenGL 1.3 Specification.
```

Overview

```
    This extension generalizes the GL_ARB_shadow extension to support all
    eight binary texture comparison functions rather than just GL_LEQUAL
    and GL_GEQUAL.
```

IP Status

    None.

Issues

```
    (1) What should this extension be called?

      RESOLUTION: EXT_shadow_funcs.  The extension adds new texture
      compare (shadow) comparison functions to ARB_shadow.

    (2) Are there issues with GL_EQUAL and GL_NOTEQUAL?

      The GL_EQUAL mode (and GL_NOTEQUAL) may be difficult to obtain
      well-defined behavior from. This is because there is no guarantee
      that the divide done by the shadow mapping r/q division is going
      to exactly match the z/w perspective divide and depth range scale
      & bias used to generate depth values.  Perhaps it can work in a
      well-defined manner in orthographic views or if you can guarantee
      that the texture hardware's r/q is computed with the same hardware
      used to compute z/w (NVIDIA's NV_texture_shader extension can
      provide such a guarantee).
```

Similiarly, GL_LESS and GL_GREATER or only different from GL_LEQUAL and GL_GEQUAL respectively by a single unit of depth precision which may make the difference between these modes very subtle.

Additions to Chapter 3 of the 1.3 Specification (Rasterization)

Section 3.8.4, Texture Parameters, p. 133, update table 3.19 with the following new legal values for TEXTURE_COMPARE_FUNC_ARB:

Name	Type	Legal Values
TEXTURE_COMPARE_FUNC_ARB	enum	LEQUAL, GEQUAL, LESS, GREATER, EQUAL, NOTEQUAL, ALWAYS, NEVER

After section 3.8.12, Texture Environments and Texture Functions, p. 149, update the texture compare pseudo-code in section 3.8.13.1 (as added by ARB_shadow):

```
if TEXTURE_COMPARE_MODE_ARB = NONE

    r = Dt

else if TEXTURE_COMPARE_MODE_ARB = COMPARE_R_TO_TEXTURE_ARB

    if TEXTURE_COMPARE_FUNC_ARB = LEQUAL

          { 1.0,  if R <= Dt
      r = {
          { 0.0,  if R > Dt

    else if TEXTURE_COMPARE_FUNC_ARB = GEQUAL

          { 1.0,  if R >= Dt
      r = {
          { 0.0,  if R < Dt

    else if TEXTURE_COMPARE_FUNC_ARB = LESS

          { 1.0,  if R < Dt
      r = {
          { 0.0,  if R >= Dt

    else if TEXTURE_COMPARE_FUNC_ARB = GREATER
```

```
                 { 1.0,  if R > Dt
             r = {
                 { 0.0,  if R <= Dt

            else if TEXTURE_COMPARE_FUNC_ARB = EQUAL

                 { 1.0,  if R == Dt
             r = {
                 { 0.0,  if R != Dt

            else if TEXTURE_COMPARE_FUNC_ARB = NOTEQUAL

                 { 1.0,  if R != Dt
             r = {
                 { 0.0,  if R == Dt

            else if TEXTURE_COMPARE_FUNC_ARB = ALWAYS

             r = 1.0

            else if TEXTURE_COMPARE_FUNC_ARB = NEVER

             r = 0.0

            endif

            if DEPTH_TEXTURE_MODE_ARB = LUMINANCE

                Lt = r

            else if DEPTH_TEXTURE_MODE_ARB = INTENSITY

                It = r

            else if DEPTH_TEXTURE_MODE_ARB = ALPHA

                At = r

            endif

        endif
```

Support

Mesa.

Selected NVIDIA GPUs: NV1x (GeForce 256, GeForce2, GeForce4 MX, GeForce4 Go, Quadro, Quadro2), NV2x (GeForce3, GeForce4 Ti, Quadro DCC, Quadro4 XGL), and NV3x (GeForce FX 5xxxx, Quadro FX 1000/2000/3000). NV3 (Riva 128) and NV4 (TNT, TNT2) GPUs and NV4x GPUs do NOT support this functionality (no hardware support). Future NVIDIA GPU designs will no longer support paletted textures.

S3 ProSavage, Savage 2000.

3Dfx Voodoo3, Voodoo5.

3Dlabs GLINT.

Dependencies

EXT_paletted_texture is required.

Overview

EXT_shared_texture_palette defines a shared texture palette which may be used in place of the texture object palettes provided by EXT_paletted_texture. This is useful for rapidly changing a palette common to many textures, rather than having to reload the new palette for each texture. The extension acts as a switch, causing all lookups that would normally be done on the texture's palette to instead use the shared palette.

Issues

* Do we want to use a new <target> to ColorTable to specify the shared palette, or can we just infer the new target from the corresponding Enable?

* A future extension of larger scope might define a "texture palette object" and bind these objects to texture objects dynamically, rather than making palettes part of the texture object state as the current EXT_paletted_texture spec does.

* Should there be separate shared palettes for 1D, 2D, and 3D textures?

  Probably not; palette lookups have nothing to do with the dimensionality of the texture. If multiple shared palettes are needed, we should define palette objects.

* There's no proxy mechanism for checking if a shared palette can be defined with the requested parameters. Will it suffice to assume that if a texture palette can be defined, so can a shared palette with the same parameters?

* The changes to the spec are based on changes already made for EXT_paletted_texture, which means that all three documents must be referred to. This is quite difficult to read.

* The changes to section 3.8.6, defining how shared palettes are enabled and disabled, might be better placed in section 3.8.1. However, the underlying EXT_paletted_texture does not appear to modify these sections to define exactly how palette lookups are done, and it's not clear where to put the changes.

* How does the shared texture palette interact with multitexture support? There is a single global shared texture palette that all texture units utilize (as opposed to a shared texture palette per texture unit).

New Procedures and Functions

None

New Tokens

Accepted by the <pname> parameters of GetBooleanv, GetIntegerv, GetFloatv, GetDoublev, IsEnabled, Enable, Disable, ColorTableEXT, ColorSubTableEXT, GetColorTableEXT, GetColorTableParameterivEXT, and GetColorTableParameterfd EXT:

```
SHARED_TEXTURE_PALETTE_EXT              0x81FB
```

Additions to Chapter 2 of the 1.1 Specification (OpenGL Operation)

None

Additions to Chapter 3 of the 1.1 Specification (Rasterization)

Section 3.8, 'Texturing,' subsection 'Texture Image Specification' is modified as follows:

In the Palette Specification Commands section, the sentence beginning 'target specifies which texture is to' should be changed to:

target specifies the texture palette or shared palette to be changed, and may be one of TEXTURE_1D, TEXTURE_2D, PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, TEXTURE_3D_EXT, PROXY_TEXTURE_3D_EXT, or SHARED_TEXTURE_PALETTE_EXT.

In the 'Texture State and Proxy State' section, the sentence beginning 'A texture's palette is initially...' should be changed to:

There is also a shared palette not associated with any texture, which may override a texture palette. (Even when multiple texture units are available, there is still only a single shared texture palette.) All palettes are initially...

Section 3.8.6, 'Texture Application' is modified by appending the following:

Use of the shared texture palette is enabled or disabled using the generic Enable or Disable commands, respectively, with the symbolic constant SHARED_TEXTURE_PALETTE_EXT.

The required state is one bit indicating whether the shared palette is enabled or disabled. In the initial state, the shared palettes is disabled.

Additions to Chapter 4 of the 1.1 Specification (Per-Fragment Operations and the Frame buffer)

None

Additions to Chapter 5 of the 1.1 Specification (Special Functions)

None

Additions to Chapter 6 of the 1.1 Specification (State and State Requests)

In the section on GetTexImage, the sentence beginning 'If format is not COLOR_INDEX...' should be changed to:

If format is not COLOR_INDEX, the texture's indices are passed through the texture's palette, or the shared palette if one is enabled, and the resulting components are assigned among R, G, B, and A according to Table 6.1.

In the GetColorTable section, the first sentence of the second paragraph should be changed to read:

GetColorTableEXT retrieves the texture palette or shared palette given by target.

The first sentence of the third paragraph should be changed to read:

Palette parameters can be retrieved using

```
void GetColorTableParameterivEXT(enum target, enum pname, int *params);
void GetColorTableParameterfvEXT(enum target, enum pname, float *params);
```

target specifies the texture palette or shared palette being queried and pname controls which parameter value is returned.

Additions to the GLX Specification

None

New State

Get Value	Type	Get Command	Initial Value	Description	Sec	Attribute
SHARED_TEXTURE_PALETTE_EXT	B	IsEnabled	False	shared texture palette enable	3.8.6	texture/enable
SHARED_TEXTURE_PALETTE_EXT	I	GetColorTableEXT	empty	shared texture palette table	3.8	-
COLOR_TABLE_FORMAT_EXT	Zn	GetColorTableParameterivEXT	RGBA	shared texture palette format	3.8	-
COLOR_TABLE_WIDTH_EXT	Z+	GetColorTableParameteriv	0	shared texture palette width	3.8	-

New Implementation Dependent State

None

Revision History

July 10, 2002 - Added "New State" tables entries. Clarify that there is a single global shared texture palette, rather than a per-texture unit palette when multitexture is available.

March 24, 2004 - Document vendor support for this extension; note that future NVIDIA GPU designs will not support this extension.

Overview

Stencil-only framebuffer clears are increasingly common as 3D applications are now using rendering algorithms such as stenciled shadow volume rendering for multiple light sources in a single frame, recent "soft" stenciled shadow volume techniques, and stencil-based constructive solid geometry techniques. In such algorithms there are multiple stencil buffer clears for each depth buffer clear. Additionally in most cases, these algorithms do not require all of the 8 typical stencil bitplanes for their stencil requirements. In such cases, there is the potential for unused stencil bitplanes to encode a "stencil clear tag" in such a way to reduce the number of actual stencil clears. The idea is that switching to an unused stencil clear tag logically corresponds to when an application would otherwise perform a framebuffer-wide stencil clear.

This extension exposes an inexpensive hardware mechanism for amortizing the cost of multiple stencil-only clears by using a client-specified number of upper bits of the stencil buffer to maintain a per-pixel stencil tag.

The upper bits of each stencil value is treated as a tag that indicates the state of the upper bits of the "stencil clear tag" state when the stencil value was last written. If a stencil value is read and its upper bits containing its tag do NOT match the current upper bits of the stencil clear tag state, the stencil value is substituted with the lower bits of the stencil clear tag (the reset value).

Either way, the upper tag bits of the stencil value are ignored by subsequent stencil function and operation processing of the stencil value.

When a stencil value is written to the stencil buffer, its upper bits are overridden with the upper bits of the current stencil clear tag state so subsequent reads, prior to any subsequent stencil clear tag state change, properly return the updated lower bits.

In this way, the stencil clear tag functionality provides a way to replace multiple bandwidth-intensive stencil clears with very inexpensive update of the stencil clear tag state.

If used as expected with the client specifying 3 bits for the stencil tag, every 7 of 8 stencil-only clears of the entire stencil buffer can be substituted for an update of the current stencil clear tag rather than an actual update of all the framebuffer's stencil values. Still, every 8th clear must be an actual stencil clear. The net effect is that the aggregate cost of stencil clears is reduced by a factor of 1/(2^n) where n is the number of bits devoted to the stencil tag.

The application specifies two new pieces of state: 1) the number of upper stencil bits, n, assigned to maintain the tag bits for each stencil value within the stencil buffer, and 2) a stencil clear tag value that packs the current tag and a reset value into a single integer values. The upper n bits of the stencil clear tag value specify the current tag while the lower s-min(n,s) bits specify the current reset value, where s is the number of bitplanes in the stencil buffer and n is the current number of stencil tag bits.

If zero stencil clear tag bits are assigned to the stencil tag encoding, then the stencil buffer operates in the conventional manner.

Issues

1) *Can the stencil clear tag state be switched at anytime?*

RESOLUTION: Yes. The state controls the interpretation of the stencil values without actually change the values within the stencil buffer. So, for example, it is possible to render to the stencil buffer with 3 tag bits and then switch to 4 tag bits and a different reset value.

The effect of changing stencil clear tag state is well-defined though perhaps not useful.

The motivation for this decision is to make the underlying hardware implementation simple and not encumber operations such as stencil readback with extra expense to re-interpret stencil values.

2) *Can two distinct OpenGL rendering contexts render to the same framebuffer but with different stencil clear tag state?*

RESOLUTION: Yes. The stencil buffer contains raw stencil values whose interpretation and update may be different for the two contexts, but the values themselves are the same.

The motivation for this is that it avoids trying to coordinate two different contexts into maintaining the same interpretation of the stencil buffer. Different contexts can each view the stencil buffer values differently based on their own stencil clear tag state.

3) *For the purposes of the stencil comparison and stencil operations, how are upper bits of the read stencil value treated?*

RESOLUTION: The upper n bits where n is the current value of stencil tag bits (GL_STENCIL_TAG_BITS_EXT) are masked to zero when n is greater than zero.

For example, if a raw stencil value is 0xFA and the current stencil tag bits state is 3 with a stencil clear tag value of 0x82, the effective read stencil value is 0x02 because the upper 3 bits of 0xFA do not match the upper 3 bits of 0x82 and so the effective read stencil value is replaced with the lower 5 bits of 0x82 which is 0x02 while masking to zero the upper 3 bits. If instead, the stencil clear tag value was 0xEB, then the effective read stencil value is 0x1A because the upper 3 bits of 0xEB match the upper 3 bits of 0xFF so the effective read stencil value is 0xFA with the upper 3 bits masked to zero.

4) *How does the GL_INCR operation work when the stencil tag bits value is greater than zero?*

RESOLUTION: GL_INCR saturates to the value 2^(s-min(n,s))-1 where s is the number of stencil bits in the stencil buffer and n is the current value of stencil tag bits, rather than saturating to 2^s-1 or wrapping.

The motivation for this is to ensure that the stencil clear tag mechanism can fully emulate stencil buffers with fewer than s bits.

5) *What is the initial number of stencil tag bits?*

RESOLUTION: Zero. This is consistent with the conventional operation of the stencil buffer. The stencil clear tag value state is ignored when the stencil tag bits value is zero.

6) *Should glClear involving GL_STENCIL_BUFFER_BIT be subject to the stencil clear tag or tag bits state?*

RESOLUTION: No. An actual clear to the stencil buffer needs to reset the bitplanes allocated to the upper stencil tag bits as well as the lower bitplanes. So the stencil mask applies, but the stencil clear tag and tag bits state is ignored by glClear.

7) *Should glDrawPixels operations be subject to the stencil clear tag functionality?*

RESOLUTION: Yes. glDrawPixels to stencil already abides by the stencil write mask. Conceptually, think of glDrawPixels to stencil as being the GL_REPLACE operation where the value to be written comes from the glDrawPixels image rectangle rather than the stencil reference value.

The motivation is to allow the stencil clear tag mechanism to fully simulate a stencil buffer with fewer stencil bits.

If you want to write the entire stencil value, including upper bits that are allocated to encode the stencil tag, simply set the stencil tag bits state to zero for the duration of the glDrawPixels command.

8) *Should glReadPixels operations of type GL_STENCIL_INDEX be subject to the stencil clear tag state?*

RESOLUTION: Yes. So if you read stencil values from the stencil buffer, the n upper bits of each stencil value is compared to the n upper bits of the stencil clear tag value and if they mismatch, the lower s-min(n,s) bits of the stencil clear tag value (the reset value) are returned instead, where s is the number of stencil bitplanes and n is the current stencil tag bits value. In any case, the upper n bits of the stencil value are zeroed.

The motivation is to allow the stencil clear tag mechanism to fully simulate a stencil buffer with fewer stencil bits.

If you want to read the entire stencil value, including upper bits that are allocated to encode the stencil tag, then set the stencil tag bits state to zero for the duration of the glReadPixels command.

9) *Should glCopyPixels operations of type GL_STENCIL_INDEX be subject to the stencil clear tag state?*

RESOLUTION: Yes, because glReadPixels and glDrawPixels are both affected and glCopyPixels is defined in terms of glReadPixels and glDrawPixels.

10) *Should the current tag and reset value in the current stencil clear tag be packed into a single value where the stencil tag bits value divides the upper tag value bits from the lower reset value bits?*

RESOLUTION: Yes. This makes a lot of sense because there are always s bits required where n bits are for the current tag value and s-min(n,s) bits are for the reset value, where s is the number of stencil bitplanes and n is the number of stencil tag bits.

This packing also makes the explanation of how bit comparisons and the required masking operations operate in the specification language. It also naturally corresponds to how a hardware implementation would maintain the state.

11) *Clears can be scissored to only update a subrectangle of the entire framebuffer. Can the stencil clear tag facility accelerate scissored clears that do not clear the entire framebuffer?*

RESOLUTION: No. The stencil clear tag state is a single per-context state value that applies to the entire framebuffer.

For scissored clears to sufficiently small enough subrectangles of the screen, it may be more advantageous to perform an actual scissored clear if changing the current stencil clear tag value would be better used to save an subsequent actual stencil clear of the entire (or nearly the entire) framebuffer.

Doom 3 uses scissored clears when performing per-light stencil clears for its stenciled shadow volumes where the scissor is a 2D bound for the light's illumination.

12) *How does this extension interact with EXT_stencil_two_side or other two-sided stencil testing functionality such as that provided by OpenGL 2.0?*

RESOLUTION: The stencil clear tag state is not two-sided because it reflects the manner that stencil values in the stencil buffer are read to and written from the buffer rather than anything to do with the facingness of primitives.

13) *How does the GL_KEEP operation operate when the value of GL_STENCIL_TAG_BITS_EXT is greater than zero?*

RESOLUTION: GL_KEEP means no stencil write is performed so the pixel's stencil value is completely unchanged. This means the pixel's stencil value will still have the old stencil tag.

The rationale for this is that GL_KEEP will always avoid memory writes to the stencil buffer, even when the current stencil tag state does not match the tag of pixel's stencil value.

All other stencil operations must actually write the stencil tag bits into the upper bits of the pixel's stencil value if the old value's tag does not match the current stencil tag state. For example, if the value of GL_STENCIL_TAG_BITS_EXT is 3, the value of GL_STENCIL_CLEAR_TAG_EXT is 0x80, the stencil write mask is 0xFF, and a pixel's stencil value is 0x00, the result of a GL_ZERO stencil operation for this pixel is to write 0x80. into the stencil buffer.

14) *How does a stencil write mask of zero operate when the value of GL_STENCIL_GENERATION_BITS_EXT is greater than zero?*

RESOLUTION: A stencil write mask of zero means no stencil write is performed so the pixel's stencil value is completely unchanged. This means the pixel's stencil value will still have the old stencil tag bits.

The rationale for this is essentially the same for GL_KEEP's behavior in the previous issue.

15) *Conceptually, how does the stencil clear tag functionality augment the existing stencil processing pipeline?*

RESOLUTION: Unextended OpenGL stencil processing (ignoring the depth test interactions) says:

```
  read stencil value
    |
    v
  evaluate stencil function
    |
    v
  apply appropriate stencil operation
    |
    v
  if operation is non-GL_KEEP, write stencil value
```

The EXT_stencil_clear_tag functionality augments this pipeline with two new stages:

```
  read stencil value
    |
    v
  perform stencil clear tag "read merge"
    |
    v
  evaluate stencil function
    |
    v
  apply appropriate stencil operation
    |
    v
  perform stencil clear tag "write merge"
    |
    v
  if a non-KEEP operation, write stencil value
```

The new stencil clear tag merge stages are pass-through operations if the value of GL_STENCIL_TAG_BITS_EXT is zero (the initial state).

16) *Can you provide an example of how this stencil clear tag mechanism could be used to eliminate stencil clears for a stenciled shadow volume application with multiple light sources per frame.*

First assume the application's shadow complexity is such that scenes never exceed a shadow complexity of 31 (or 63 or 127) at any pixel, meaning a 5 (or 6 or 7) bit stencil buffer is sufficient to avoid artifacts.

The code assumes "Z fail" shadow volume rendering with two-sided stencil testing and an 8-bit stencil buffer.

So initialize the stencil-related state as follows:

```
  const GLint stencilTagBits = 3;  // or 2 or 1
  const int hasStencilClearTagExtension =
      queryExtension("GL_EXT_stencil_clear_tag");

  GLint stencilBits;
  GLuint maxStencilValue;
  GLint tagInit;
  GLint tagDecrement;
  GLint stencilClearTag;

  if (hasStencilClearTagExtension) {
      glGetIntegerv(GL_STENCIL_BITS, &stencilBits);
      maxStencilValue = (1U<<stencilBits)-1;
      assert(stencilBits > stencilTagBits);
      tagDecrement = 1<<(stencilBits - stencilTagBits);
      tagInit = ~(tagDecrement-1) & maxStencilValue;

      glStencilClearTagEXT(stencilTagBits, tagInit);
      glStencilClear(tagInit);
  } else {
      glStencilClear(0);
  }

  glEnable(GL_STENCIL_TWO_SIDE_EXT);
  glActiveStencilFaceEXT(GL_BACK);
  glStencilMask(~0);
  glActiveStencilFaceEXT(GL_FRONT);
  glStencilMask(~0);
```

Then rendering one frame of a shadowed scene looks like:

```
  int i;

  glDepthMask(1);
  glColorMask(1,1,1,1);

  if (hasStencilClearTagExtension) {
      stencilClearTag = tagInit;
      glStencilClearTagEXT(stencilTagBits, stencilClearTag);
  }
  glClear(GL_STENCIL_BUFFER_BIT |
          GL_DEPTH_BUFFER_BIT |
          GL_COLOR_BUFFER_BIT);

  glDisable(GL_BLEND);
  glDisable(GL_STENCIL_TEST);
  glDepthFunc(GL_LESS);
  glEnable(GL_DEPTH_TEST);

  renderDepthAndAmbient();

  glEnable(GL_BLEND);
  glBlendFunc(GL_ONE, GL_ONE);
  glEnable(GL_STENCIL_TEST);
  glDepthMask(0);
  glDepthFunc(GL_EQUAL);
```

```
      for (i=0; i<numberOfLights; i++) {
          if (i == 0) {
              // First light can hitches ride on frame's initial gang clear
          } else {
              // Subsequent lights must effect a clear
              if (hasStencilClearTagExtension) {
                  // Did start on a new set of tags?
                  if (stencilClearTag == tagInit) {
                      // If so, do real stencil clear and reset stencilClearTag.
                      glClear(GL_STENCIL_BUFFER_BIT);
                      // Decrement to next tag.
                      stencilClearTag -= tagDecrement;
                  }
                  // Are we out of tags?
                  else if (stencilClearTag == 0) {
                      // Reset to the initial tag.
                      stencilClearTag = tagInit;
                  } else {
                     // Decrement to next tag.
                     stencilClearTag -= tagDecrement;
                  }
                  glStencilClearTagEXT(stencilTagBits, stencilClearTag);
              } else {
                  // Actual per-light clear needed
                  glClear(GL_STENCIL_BUFFER_BIT);
              }
          }
          glActiveStencilFaceEXT(GL_BACK);
              glStencilFunc(GL_ALWAYS, 0, ~0);
              glStencilOp(GL_KEEP, GL_INCR_WRAP, GL_KEEP);
          glActiveStencilFaceEXT(GL_FRONT);
              glStencilFunc(GL_ALWAYS, 0, ~0);
              glStencilOp(GL_KEEP, GL_DECR_WRAP, GL_KEEP);
          glColorMask(0,0,0,0);

          renderShadowVolumesForLight(i);

          glActiveStencilFaceEXT(GL_BACK);
              glStencilFunc(GL_EQUAL, 0, ~0);
              glStencilOp(GL_KEEP, GL_KEEP, GL_KEEP);
          glActiveStencilFaceEXT(GL_FRONT);
              glStencilFunc(GL_EQUAL, 0, ~0);
              glStencilOp(GL_KEEP, GL_KEEP, GL_KEEP);
          glColorMask(1,1,1,1);

          renderLightingContributionForLight(i);
      }
```

A smarter implementation could include computation of the scissor (and depth bounds) for each light source. If the number of lights exceeds the number of available stencil tags, the lights with the smallest scissor area could be performed as actual scissored clears so the clears to the largest regions could be done as stencil clear tag state updates.

stencilTagBits can be adjusted based on the number of active lights. For example, if there are only 4 lights active, stencilTagBits could be 2 instead of 3 and thereby recover a bit of stencil precision for the shadow volume count.

17) *Why "s-min(n,s)" instead of simply "s-n" where s is the number of stencil bits and n is the number of stencil tag bits?*

RESOLVED: This makes sure if a context migrates to a drawable with fewer stencil bits than a drawable had when glStencilClearTagEXT was last called, the effect should be well-defined.

For example, if glStencilClearTagEXT(3,0) is called with an 8-bit stencil buffer and then that context is bound to a drawable with no stencil buffer (effectively, 0 bits), s-min(n,s) is zero rather than s-n being -3.

18) *Should the stencil reference value be ANDed with 2^(s-min(n,s))-1?*

RESOLOVED: Yes. this way the reference value and the compared stencil value compare a matching number of bits.

New Procedures and Functions

```
    StencilClearTagEXT(sizei stencilTagBits,
                       uint stencilClearTag)
```

New Tokens

Accepted by the <pname> parameter of GetBooleanv, GetIntegerv, GetFloatv, and GetDoublev:

```
        STENCIL_TAG_BITS_EXT                0x88F2
        STENCIL_CLEAR_TAG_VALUE_EXT         0x88F3
```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

None

Additions to Chapter 3 of the GL Specification (Rasterization)

None

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

Section 4.1.5 "Stencil Test" (page 174), add after the 1st paragraph:

"The command

```
       void StencilClearTagEXT(sizei stencilTagBits,
                               uint stencilClearTag);
```

controls the stencil clear tag state. stencilTagBits is a count of the number of most-significant stencil buffer bits involved in the stencil clear tag update. The error INVALID_VALUE is generated if stencilTagBits is negative or greater or equal to s."

Add after the 2nd sentence in the 2nd paragraph:

"The effective reference value used for the stencil comparison is ref ANDed with 2^(s-min(n,s))-1, where n is equal to stencilTagBits."

```
    Addd after the 2nd paragraph:

    "The stored stencil value used for the stencil comparison and
    subsequent stencil operations is obtained by reading the pixel's
    corresponding stencil value from the stencil buffer and possibly
    modifying that value based on the stencil clear tag state.

    The stored stencil value is modified prior to the stencil comparison
    if n (again where n is equal to stencilTagBits) is greater than zero;
    otherwise if zero, the stored stencil value remains unmodified.
    If n is greater than zero and the n most-significant bits of
    the stored stencil value all match the corresponding bits of
    the stencilClearTag, then the stored stencil value is ANDed with
    2^(s-min(n,s))-1. If n is greater than zero and the n most-significant
    bits of the stored stencil value do NOT match all the corresponding
    bits of the stencilClearTag, then the stored stencil value becomes
    stencilClearTag ANDed with 2^(s-min(n,s))-1. "

    Change the KEEP operation description in the 4th sentence to indicate
    that KEEP does not perform the stencil clear tag write merge:

    "keeping the current value without writing the stencil buffer,"

    Change the second sentence of the fourth paragraph to read:

    "Incrementing or decrementing with saturation clamps the stencil
    value at 0 and 2^(s-min(n,s))-1 so when stencilTagBits is zero the
    maximum saturation value is the maximum representable stencil value."

    Section 4.2.5 "Fine Control of Buffer Updates" (page 185), prior to
    the paragraph describing the StencilMask command, add:

    "Writes to the stencil buffer are controlled through a combination
    of stencil mask and stencil clear tag state."

    Then add after the paragraph describing the StencilMask command:

    "If the stencil mask ANDed with s^2(s-min(n,s))-1 is zero, no write
    occurs.  Otherwise, the pixel's stencil value is written with the
    value determined by the following C-style bit-wise expression:

       ( stencilClearTag & ~tagMask         ) |
       ( newValue        &  mask &  tagMask ) |
       ( storedValue     & ~mask &  tagMask )

    where tagMask is 2^(s-min(n,s))-1, n is the value of the
    stencil tag bits state, newValue is the stencil value to
    be written (after the stored value's potential modification due to
    stencil clear tag state AND after the effect of applying a stencil
    operation to the value), and storedValue is the pixel's stored
    stencil value after to its potential modification due to stencil
    clear tag state BUT BEFORE to any stencil operation that may have
    been performed (as discussed in section 4.1.5).  When n is zero,
    this is equivalent to

       ( newValue    &  mask ) |
       ( storedValue & ~mask )

    "
```

Section 4.2.3 "Clearing the Buffers", change the ClearStencil sentence to read:

"Similarly,

```
    void ClearStencil(int s);
```

takes a single integer argument that is the value to which to clear the stencil buffer. s is masked to the number of bitplanes in the stencil buffer. Clearing stencil ignores the stencil clear tag state."

Section 4.3.1 "Writing to the Stencil Buffer", change the last sentence to say:

"Finally, each stencil index is written to its indicated location in the framebuffer, subject to the current setting of StencilMask and StencilClearTagEXT (see section 4.2.5). This means the most-significant n stencil bitplanes cannot be written by DrawPixels where n is the current number of stencil tag bits."

Section 4.3.2 "Reading Pixels - Obtaining Pixels from the Framebuffer", change third paragraph to read:

"If the format is STENCIL_INDEX, then values are taken from the stencil buffer; again, if there is no stencil buffer, the error INVALID_OPERATION occurs. If the current stencil tag bits state is zero (see section 4.2.5), the read stencil value is unmodified when read. If the current stencil tag bits state is greater than zero, then the upper most-significant n bits of the read stencil value are compared to the corresponding n bits of the stencil clear tag value, where n is the current number of stencil tag bits. If these upper bits mismatch, the read stencil value is replaced with the lower s-min(n,s) bits of the stencil clear tag state (zeroing the upper n bits), where s is the number of stencil bitplanes. If the upper bits match, the upper n bits of the read stencil value are zeroed."

Additions to Chapter 6 of the GL Specification (State and State Requests)

None

Additions to the GLX Specification

None

GLX Protocol

A new GL rendering command is added. The following command is sent to the server as part of a glXRender request:

StencilClearTagEXT

```
        2           12              rendering command length
        2           4223            rendering command opcode
        4           INT32           stencilTagBits
        4           CARD32          stencilClearTag
```

Errors

INVALID_VALUE is generated by StencilClearTagEXT if stencilTagBits is negative or greater or equal to s where s is the number of bits in the stencil buffer.

New State

(table 6.19, page 245)

Get Value	Type	Get Command	Initial Value	Sec	Attribute
STENCIL_TAG_BITS_EXT	Z+	GetIntegerv	0	4.1.5	stencil-buffer
STENCIL_CLEAR_TAG_EXT	Z+	GetIntegerv	0	4.1.5	stencil-buffer

    NV_packed_depth_stencil affects the definition of this extension.

Overview

This extension provides two-sided stencil testing where the stencil-related state (stencil operations, reference value, compare mask, and write mask) may be different for front- and back-facing polygons. Two-sided stencil testing may improve the performance of stenciled shadow volume and Constructive Solid Geometry (CSG) rendering algorithms.

Issues

Is this sufficient for shadow volume stencil update in a single pass?

RESOLUTION: Yes.

An application that wishes to increment the stencil value for rasterized depth-test passing fragments of front-facing polygons and decrement the stencil value for rasterized fragments of depth-test passing back-facing polygons in a single pass can use the following configuration:

```
  glDepthMask(0);
  glColorMask(0,0,0,0);
  glDisable(GL_CULL_FACE);
  glEnable(GL_STENCIL_TEST);
  glEnable(GL_STENCIL_TEST_TWO_SIDE_EXT);

  glActiveStencilFaceEXT(GL_BACK);
  glStencilOp(GL_KEEP,            // stencil test fail
              GL_KEEP,            // depth test fail
              GL_DECR_WRAP_EXT);  // depth test pass
  glStencilMask(~0);
  glStencilFunc(GL_ALWAYS, 0, ~0);

  glActiveStencilFaceEXT(GL_FRONT);
  glStencilOp(GL_KEEP,            // stencil test fail
              GL_KEEP,            // depth test fail
              GL_INCR_WRAP_EXT);  // depth test pass
  glStencilMask(~0);
  glStencilFunc(GL_ALWAYS, 0, ~0);

  renderShadowVolumePolygons();
```

Notice the use of EXT_stencil_wrap to avoid saturating decrements losing the shadow volume count. An alternative, using the conventional GL_INCR and GL_DECR operations, is to clear the stencil buffer to one half the stencil buffer value range, say 128 for an 8-bit stencil buffer. In the case, a pixel is "in shadow" if the final stencil value is greater than 128 and "out of shadow" if the final stencil value is 128. This does still create a potential for stencil value overflow if the stencil value saturates due to an increment or decrement. However saturation is less likely with two-sided stencil testing than the conventional two-pass approach because front- and back-facing polygons are mixed together, rather than processing batches of front-facing then back-facing polygons.

Contrast the two-sided stencil testing approach with the more or less equivalent approach using facingness-independent stencil testing:

```
  glDepthMask(0);
  glColorMask(0,0,0,0);
  glEnable(GL_CULL_FACE);
  glEnable(GL_STENCIL_TEST);

  glStencilMask(~0);
  glStencilFunc(GL_ALWAYS, 0, ~0);

  // Increment for front faces
  glCullFace(GL_BACK);
  glStencilOp(GL_KEEP,   // stencil test fail
              GL_KEEP,   // depth test fail
              GL_INCR);  // depth test pass

  renderShadowVolumePolygons();

  // Decrement for back faces
  glCullFace(GL_FRONT);
  glStencilOp(GL_KEEP,   // stencil test fail
              GL_KEEP,   // depth test fail
              GL_DECR);  // depth test pass

  renderShadowVolumePolygons();
```

Notice that all the render work implicit in renderShadowVolumePolygons is performed twice with the conventional approach, but only once with the two-sided stencil testing approach.

Should there be just front and back stencil test state, or should the stencil write mask also have a front and back state?

RESOLUTION: Both the stencil test and stencil write mask state should have front and back versions.

The shadow volume application for two-sided stencil testing does not require differing front and back versions of the stencil write mask, but we anticipate other applications where front and back write masks may be useful.

For example, it may be useful to draw a convex polyhedra such that (assuming the stencil bufer is cleared to the binary value 1010):

1) front-facing polygons that pass the depth test set stencil bit 0

2) front-facing polygons that fail the depth test zero stencil bit 1

3) back-facing polygons that pass the depth test set stencil bit 2

4) back-facing polygons that fail the depth test zero stencil bit 3

This could be accomplished in a single rendering pass using:

```
  glStencilMask(~0);
  glStencilClear(0xA);
  glClear(GL_STENCIL_BUFFER_BIT);

  glDepthMask(0);
  glColorMask(0,0,0,0);
  glDisable(GL_CULL_FACE);
  glEnable(GL_STENCIL_TEST);
  glEnable(GL_STENCIL_TEST_TWO_SIDE_EXT);

  glActiveStencilFaceEXT(GL_BACK);
  glStencilOp(GL_KEEP,      // stencil test fail
              GL_ZERO,      // depth test fail
              GL_REPLACE);  // depth test pass
  glStencilMask(0xC);
  glStencilFunc(GL_ALWAYS, 0x4, ~0);

  glActiveStencilFaceEXT(GL_FRONT);
  glStencilOp(GL_KEEP,      // stencil test fail
              GL_ZERO,      // depth test fail
              GL_REPLACE);  // depth test pass
  glStencilMask(0x3);
  glStencilFunc(GL_ALWAYS, 0x1, ~0);

  renderConvexPolyhedra();
```

Is there a performance advantage to using two-sided stencil testing?

RESOLUTION: It depends.

In a fill-rate limited situation, rendering front-facing primitives, then back-facing primitives in two passes will generate the same number of rasterized fragments as rendering front- and back-facing primitives in a single pass.

However, in other situations that are CPU-limited, transform-limited, or setup-limited, two-sided stencil testing can be faster than the conventional two-pass face culling rendering approaches. For example, if a lengthy vertex program is executed for every shadow volume vertex, rendering the shadow volume with a single two-sided stencil testing pass is advantageous.

Often applications using stencil shadow volume techniques require substantial CPU resources to determine potential silhouette boundaries to project shadow volumes from. If the shadow volume geometry generated by the CPU is only required to be sent to the GL once per-frame (rather than twice with the conventional technique), that can ease the CPU burden required to implement stenciled shadow volumes.

Should GL_FRONT_AND_BACK be accepted by glActiveStencilFaceEXT?

RESOLUTION: No.

GL_FRONT_AND_BACK is useful when materials are being updated for two-sided lighting because the front and back material are often identical and may change frequently (glMaterial calls are allowed within glBegin/glEnd pairs).

Two-sided stencil has no similiar performance justification.

It is also likely that forcing implementations to support this mode would increase the amount of overhead required to set stencil state, even for applications that don't use two-sided stencil.

How should the two-sided stencil enable operate?

RESOLUTION: It should be modeled after the way two-sided lighting works. There is a GL_LIGHTING enable and then an additional two-sided lighting mode. Unlike two-sided lighting which is a light model boolean, the two-sided stencil testing is a standard enable named GL_STENCIL_TEST_TWO_SIDE_EXT.

Here is the pseudo-code for the stencil testing enables:

```
if (glIsEnabled(GL_STENCIL_TEST)) {
  if (glIsEnabled(GL_STENCIL_TEST_TWO_SIDE_EXT) && primitiveType == polygon) {
    use two-sided stencil testing
  } else {
    use conventional stencil testing
  }
} else {
  no stencil testing
}
```

How should the two-sided stencil interact with glPolygonMode?

RESOLUTION: Primitive type is determined by the begin mode so GL_TRIANGLES, GL_TRIANGLE_STRIP, GL_QUAD_STRIP, GL_QUADS, GL_TRIANGLE_FAN, and GL_POLYGON generate polygon primitives. If the polygon mode is set such that lines or points are rasterized, two-sided stencil testing still operates based on the original polygon facingness if stencil testing and two-sided stencil testing are enabled.

This is consistent with how two-sided lighting and face culling interact with glPolygonMode.

New Procedures and Functions

```
void ActiveStencilFaceEXT(enum face);
```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

    None

Additions to Chapter 3 of the GL Specification (Rasterization)

    None

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

 -- Section 4.1.5 "Stencil test"

    Replace the first paragraph in the section with:

    "The stencil test conditionally discards a fragment based on the
    outcome of a comparison between the value in the stencil buffer at
    location (xw,yw) and a reference value.

    The test is enabled or disabled with the Enable and Disable commands,
    using the symbolic constant STENCIL_TEST. When disabled, the stencil
    test and associated modifications are not made, and the fragment is
    always passed.

    Stencil testing may operate in a two-sided mode. Two-sided stencil
    testing is enabled or disabled with the Enable and Disable commands,
    using the symbolic constant STENCIL_TEST_TWO_SIDE_EXT. When stencil
    testing is disabled, the state of two-sided stencil testing does
    not affect fragment processing.

    There are two sets of stencil-related state, the front stencil
    state set and the back stencil state set. When two-sided stencil
    testing is enabled, stencil tests and writes use the front set of
    stencil state when processing fragments rasterized from non-polygon
    primitives (points, lines, bitmaps, image rectangles) and front-facing
    polygon primitives while the back set of stencil state is used when
    processing fragments rasterized from back-facing polygon primitives.
    For the purposes of two-sided stencil testing, a primitive is still
    considered a polygon even if the polygon is to be rasterized as

points or lines due to the current polygon mode. Whether a polygon is front- or back-facing is determined in the same manner used for two-sided lighting and face culling (see sections 2.13.1 and 3.5.1). When two-sided stencil testing is disabled, the front set of stencil state is always used when stencil testing fragments.

The active stencil face determines whether stencil-related commands update the front or back stencil state. The active stencil face is set with:

```
  void ActiveStencilFace(enum face);
```

where face is either FRONT or BACK. Stencil commands (StencilFunc, StencilOp, and StencilMask) that update the stencil state update the front stencil state if the active stencil face is FRONT and the back stencil state if the active stencil face is BACK. Additionally, queries of stencil state return the front or back stencil state depending on the current active stencil face.

The stencil test state is controlled with

```
   void StencilFunc(enum func, int ref, uint mask);
   void StencilOp(enum sfail, enum dpfail, enum dppass);"
```

Replace the third and second to the last sentence in the last paragraph in section 4.1.5 with:

"In the initial state, stencil testing and two-sided stencil testing are both disabled, the front and back stencil reference values are both zero, the front and back stencil comparison functions are ALWAYS, and the front and back stencil mask are both all ones. Initially, both the three front and the three back stencil operations are KEEP."

-- Section 4.2.2 "Fine Control of Buffer Updates"

Replace the last sentence of the third paragraph with:

"The initial state is for both the front and back stencil plane mask to be all ones. The clear operation always uses the front stencil write mask when clearing the stencil buffer."

-- Section 4.3.1 "Writing to the Stencil Buffer or to the Depth and Stencil Buffers"

Replace the final sentence in the first paragraph with:

"Finally, each stencil index is written to its indicated location in the framebuffer, subject to the current front stencil mask state (set with StencilMask), and if a depth component is present, if the setting of DepthMask is not FALSE, it is also written to the framebuffer; the setting of DepthTest is ignored."

Overview

Various algorithms use the stencil buffer to "count" the number of surfaces that a ray passes through. As the ray passes into an object, the stencil buffer is incremented. As the ray passes out of an object, the stencil buffer is decremented.

GL requires that the stencil increment operation clamps to its maximum value. For algorithms that depend on the difference between the sum of the increments and the sum of the decrements, clamping causes an erroneous result.

This extension provides an enable for both maximum and minimum wrapping of stencil values. Instead, the stencil value wraps in both directions.

Two additional stencil operations are specified. These new operations are similiar to the existing INCR and DECR operations, but they wrap their result instead of saturating it. This functionality matches the new stencil operations introduced by DirectX 6.

Section 4.1.4 "Stencil Test" (page 144), change the 3rd paragraph to read:

"... The symbolic constants are KEEP, ZERO, REPLACE, INCR, DECR, INVERT, INCR_WRAP_EXT, and DECR_WRAP_EXT. The correspond to keeping the current value, setting it to zero, replacing it with the reference value, incrementing it with saturation, decrementing it with saturation, bitwise inverting it, incrementing it without saturation, and decrementing it without saturation. For purposes of incrementing and decrementing, the stencil bits are considered as an unsigned integer. Incrementing or decrementing with saturation will clamp values at 0 and the maximum representable value. Incrementing or decrementing without saturation will wrap such that incrementing the maximum representable value results in 0 and decrementing 0 results in the maximum representable value. ..."

EXT_abgr affects the definition of this extension
EXT_texture is required

Overview

This extension defines 3-dimensional texture mapping. In order to define a 3D texture image conveniently, this extension also defines the in-memory formats for 3D images, and adds pixel storage modes to support them.

One important application of 3D textures is rendering volumes of image data.

New Procedures and Functions

```
void TexImage3DEXT(enum target,
                   int level,
                   enum internalformat,
                   sizei width,
                   sizei height,
                   sizei depth,
                   int border,
                   enum format,
                   enum type,
                   const void* pixels);
```

```

Additions to Chapter 2 of the GL Specification (OpenGL Operation)

None

Additions to Chapter 3 of the GL Specification (Rasterization)

The pixel storage modes are augmented to support 3D image formats in memory. Table 3.1 is replaced with the table below:

Parameter Name	Type	Initial Value	Valid Range
UNPACK_SWAP_BYTES	boolean	FALSE	TRUE/FALSE
UNPACK_LSB_FIRST	boolean	FALSE	TRUE/FALSE
UNPACK_ROW_LENGTH	integer	0	[0, infinity]
UNPACK_SKIP_ROWS	integer	0	[0, infinity]
UNPACK_SKIP_PIXELS	integer	0	[0, infinity]
UNPACK_ALIGNMENT	integer	4	1, 2, 4, 8
UNPACK_IMAGE_HEIGHT_EXT	integer	0	[0, infinity]
UNPACK_SKIP_IMAGES_EXT	integer	0	[0, infinity]

Table 3.1: PixelStore parameters pertaining to one or more of DrawPixels, TexImage1D, TexImage2D, and TexImage3DEXT.

When TexImage3DEXT is called, the groups in memory are treated as being arranged in a sequence of adjacent rectangles. Each rectangle is a 2-dimensional image, whose size and organization are specified by the <width> and <height> parameters to TexImage3DEXT. The values of UNPACK_ROW_LENGTH and UNPACK_ALIGNMENT control the row-to-row spacing in these images in exactly the manner described in the GL Specification for

2-dimensional images. If the value of UNPACK_IMAGE_HEIGHT_EXT is not positive, then the number of rows in each 2-dimensional image is <height>; otherwise the number of rows is UNPACK_IMAGE_HEIGHT_EXT. Each 2-dimensional image comprises an integral number of rows, and is exactly adjacent to its neighbor images.

The mechanism for selecting a sub-volume of a 3-dimensional image builds on the mechanism for selecting a sub-rectangle of groups from a larger containing rectangle. If UNPACK_SKIP_IMAGES_EXT is positive, the pointer is advanced by UNPACK_SKIP_IMAGES_EXT times the number of elements in one 2-dimensional image. Then <depth> 2-dimensional images are processed, each having a subimage extracted in the manner described in the GL Specification for 2-dimensional images.

The selected groups are processed as though they were part of a 2-dimensional image. When the final R, G, B, and A components have been computed for a group, they are assigned to components of a texel as described by Table 3.6 in the EXT_texture extension. Counting from zero, each resulting Nth texel is assigned internal integer coordinates [i,j,k], where

```
    i = (N mod width) - border

    j = ((N div width) mod height) - border

    k = ((N div (width * height)) mod depth) - border
```

and the div operator performs integer division with truncation. Thus the last 2-dimensional image of the 3-dimensional image is indexed with the highest value of k. The dimensions of the 3-dimensional texture image are <width> x <height> x <depth>. Integer values that will represent the base-2 logarithm of these dimensions are n, m, and l, defined such that

```
    width = 2**n + (2 * border)

    height = 2**m + (2 * border)

    depth = 2**l + (2 * border)
```

It is acceptable for an implementation to vary its allocation of internal component resolution based any TexImage3DEXT parameter, but the allocation must not be a function of any other factor, and cannot be changed once it is established. In particular, allocations must be invariant -- the same allocation must be made each time a texture image is specified with the same parameter values. Provision is made for an application to determine what component resolutions are available without having to fully specify the texture (see below).

Texture Wrap Modes

The additional token value TEXTURE_WRAP_R_EXT is accepted by TexParameteri, TexParameterv, TexParameteriv, and TexParameterfv, causing table 3.7 to be replaced with the table below:

Name	Type	Legal Values
TEXTURE_WRAP_S	integer	CLAMP, REPEAT
TEXTURE_WRAP_T	integer	CLAMP, REPEAT
TEXTURE_WRAP_R_EXT	integer	CLAMP, REPEAT
TEXTURE_MIN_FILTER	integer	NEAREST, LINEAR, NEAREST_MIPMAP_NEAREST, NEAREST_MIPMAP_LINEAR, LINEAR_MIPMAP_NEAREST, LINEAR_MIPMAP_LINEAR
TEXTURE_MAG_FILTER	integer	NEAREST, LINEAR
TEXTURE_BORDER_COLOR	4 floats	any 4 values in [0,1]

Table 3.7: Texture parameters and their values.

If TEXTURE_WRAP_R_EXT is set to REPEAT, then the GL ignores the integer part of R coordinates, using only the fractional part. CLAMP causes R to be clamped to the range [0, 1]. The initial state is for TEXTURE_WRAP_R_EXT to be REPEAT.

Texture Minification

Continuous coordinates s, t, u, and v are defined in figure 3.10 of the GL Specification. To discuss 3-dimensional texture mapping, coordinates r and w are defined similarly. Coordinate w is equal to -border at the "far" edge of the 3D image, understanding the image to be right-handed, with k values increasing toward the viewer. It has value depth+border at the near edge of this volume. Coordinate r has the same direction, but is normalized so that it is 0.0 and 1.0 at the "far" and "near" edges of a borderless volume. If the volume has a border, the 0.0 and 1.0 mappings of r continue to bound the core image.

The formulas for p, used to determine the level of detail, are modified by including dw/dx and dw/dy terms in the obvious ways. Equation 3.7 sums (dw/dx)**2 into the left term, and (dw/dy)**2 into the right term. Equation 3.8 has ((dw/dx * Dx + dw/dy * Dy)**2 added to the two terms under the square root. The requirements for the function f(x,y) become

1. f(x, y) is continuous and monotonically increasing in each of |du/dx|, |du/dy|, |dv/dx|, |dv/dy|, |dw/dx|, and |dw/dy|.

2. Let

```
m_u = max(|du/dx|, |du/dy|)
m_v = max(|dv/dx|, |dv/dy|)
m_w = max(|dw/dx|, |dw/dy|)
```

   Then

```
max(m_u, m_v, m_w) <= f(x, y) <= m_u + m_v + m_w
```

The i and j coordinates of the texel selected for NEAREST filtering are as defined in equations 3.9 and 3.10 of the GL Specification. Coordinate k is computed as

```
          /  floor(w),       r < 1
    k = (
          \  2**l - 1,       r = 1
```

A 2x2x2 cube of texels is selected for LINEAR filtering. The i and j coordinates of these texels are computed as defined in the GL Specification for 2-dimensional images. The k coordinates are computed as

```
           / floor(w - 1/2) mod 2**l,        TEXTURE_WRAP_R_EXT is REPEAT
    k0 = (
           \ floor(w - 1/2),                 TEXTURE_WRAP_R_EXT is CLAMP

           / (k0 + 1) mod 2**l,      TEXTURE_WRAP_R_EXT is REPEAT
    k1 = (
           \ k0 + 1,                 TEXTURE_WRAP_R_EXT is CLAMP
```

Let

```
    A = frac(u - 1/2)
    B = frac(v - 1/2)
    C = frac(w - 1/2)
```

where frac(x) denotes the fractional part of x. Let T[i,j,k] be the texel at location [i,j,k] in the texture image. Then the texture value, T, is found as

```
    T = (1-A) * (1-B) * (1-C) * T[i0,j0,k0] +
          A   * (1-B) * (1-C) * T[i1,j0,k0] +
        (1-A) *   B   * (1-C) * T[i0,j1,k0] +
          A   *   B   * (1-C) * T[i1,j1,k0] +
        (1-A) * (1-B) *   C   * T[i0,j0,k1] +
          A   * (1-B) *   C   * T[i1,j0,k1] +
        (1-A) *   B   *   C   * T[i0,j1,k1] +
          A   *   B   *   C   * T[i1,j1,k1]
```

for a 3-dimensional texture. If any of the selected T[i,j,k] in the above equation refer to a border texel with unspecified value, then the border color given by the current setting of TEXTURE_BORDER_COLOR is used instead of the unspecified value or values.

Mipmapping

TEXTURE_MIN_FILTER values NEAREST_MIPMAP_NEAREST, NEAREST_MIPMAP_LINEAR, LINEAR_MIPMAP_NEAREST, and LINEAR_MIPMAP_LINEAR each require the use of a mipmap. A 3-dimensional mipmap is an ordered set of arrays representing the same image; each array has a resolution lower than the previous one. If the texture, excluding is border, has dimensions 2**n x 2**m x 2**l, then there are exactly max(n, m, l) + 1 mipmap arrays. Each subsequent array has dimensions

```
    size(i-1) x size(j-1) x size(k-1)
```

where the dimensions of the previous array are

```
    size(i) x size(j) x size(k)
```

and

```
               /  2**x + 2*border,   x > 0
    size(x) = (
               \  1 + 2*border,      x <= 0
```

Each array in a 3-dimensional mipmap is transmitted to the GL using TexImage3DEXT; the array being set is indicated with the <level> parameter. The rules for completeness of the set of arrays are as described in the GL Specification, augmented in EXT_texture. The rules for mipmap array selection, and for filtering of the two selected arrays, are also as described in the GL Specification. Finally, the rules for texture magnification are also exactly as described in the GL Specification.

Texture Application

3-dimensional texture mapping is enabled and disabled using the generic Enable and Disable commands, with <cap> specified as TEXTURE_3D_EXT. If either or both TEXTURE_1D or TEXTURE_2D are enabled at the same time as TEXTURE_3D_EXT, the 3-dimensional texture is used.

Query support

The proxy texture PROXY_TEXTURE_3D_EXT can be used by applications to query an implementations maximum configurations just as it can be for 1-dimensional and 2-dimensional textures.

Alternate sets of partial per-level texture state are defined for the proxy texture PROXY_TEXTURE_3D_EXT. Specifically, TEXTURE_WIDTH, TEXTURE_HEIGHT, TEXTURE_DEPTH_EXT, TEXTURE_BORDER, TEXTURE_COMPONENTS, TEXTURE_RED_SIZE_EXT, TEXTURE_GREEN_SIZE_EXT, TEXTURE_BLUE_SIZE_EXT, TEXTURE_ALPHA_SIZE_EXT, TEXTURE_LUMINANCE_SIZE_EXT, and TEXTURE_INTENSITY_SIZE_EXT are maintained the the proxy texture. When TexImage3DEXT is called with <target> set to PROXY_TEXTURE_3D_EXT, these proxy state values are always respecified, even if the texture is too large to actually be used. If the texture is too large, all of these state variables are set to zero. If the texture could be accommodated by TexImage3DEXT called with <target> TEXTURE_3D_EXT, these values are set as though TEXTURE_3D_EXT were being defined. All of these state value can be queried with GetTexLevelParameteriv with <target> set to PROXY_TEXTURE_3D_EXT. Calling TexImage3DEXT with <target> PROXY_TEXTURE_3D_EXT has no effect on the actual 3-dimensional texture or its state.

There is no image associated with PROXY_TEXTURE_3D_EXT. Therefore PROXY_TEXTURE_3D_EXT cannot be used as a texture, and its image must never be queried using GetTexImage. (The error INVALID_ENUM results if this is attempted.) Likewise, there is no nonlevel-related state associated with a proxy texture, so calling GetTexParameteriv or GetTexParameterfv with <target> PROXY_TEXTURE_3D_EXT results in the error INVALID_ENUM.

Additions to Chapter 4 of the GL Specification (Per-Fragment Operations and the Framebuffer)

None

Additions to Chapter 5 of the GL Specification (Special Functions)

TexImage3DEXT with a proxy target is not included in display lists, but is instead executed immediately.

Additions to Chapter 6 of the GL Specification (State and State Requests)

3-dimensional texture images are queried using GetTexImage with its <target> parameter set to TEXTURE_3D_EXT. The assignment of texel component values to the initial R, G, B, and A components of a pixel group is described in EXT_texture. Pixel transfer and pixel storage operations are applied as if the image were 2-dimensional, except that the additional pixel storage state values PACK_IMAGE_HEIGHT_EXT and PACK_SKIP_IMAGES_EXT affect the storage of the image into memory. The correspondence of texels to memory locations is as defined for TexImage3DEXT above, substituting PACK* state for UNPACK* state in all occurrences.

Additions to the GLX Specification

None

GLX Protocol

A new GL rendering command is added. This command contains pixel data; thus it is sent to the server either as part of a glXRender request or as part of a glXRenderLarge request:

```
   TexImage3DEXT
       2           84+n+p          rendering command length
       2           4114            rendering command opcode
       1           BOOL            swap_bytes
       1           BOOL            lsb_first
       2                           unused
       4           CARD32          row_length
       4           CARD32          image_height
       4           CARD32          image_depth
       4           CARD32          skip_rows
       4           CARD32          skip_images
       4           CARD32          skip_volumes
       4           CARD32          skip_pixels
       4           CARD32          alignment
       4           ENUM            target
       4           INT32           level
       4           ENUM            internalformat
       4           INT32           width
       4           INT32           height
       4           INT32           depth
       4           INT32           size4d
       4           INT32           border
       4           ENUM            format
       4           ENUM            type
       4           CARD32          null_image
       n           LISTofBYTE      pixels
       p                           unused, p=pad(n)

       If the command is encoded in a glXRenderLarge request, the command
       opcode and command length fields above are expanded to 4 bytes each:

       4           88+n+p          rendering command length
       4           4114            rendering command opcode
```

If <width> < 0, <height> < 0, <depth> < 0, <format> is invalid or <type> is invalid, then the command is erroneous and n=0.

<pixels> is arranged as a sequence of adjacent rectangles. Each rectangle is a 2-dimensional image, whose structure is determined by the image height and the parameters <swap_bytes>, <lsb_first>, <row_length>, <skip_rows>, <skip_pixels>, <alignment>, <width>, <format>, and <type> given in the request. If <image_height> is not positive then the number of rows (i.e., the image height) is <height>; otherwise the number of rows is <image_height>.

<skip_images> allows a sub-volume of the 3-dimensional image to be selected. If <skip_images> is positive, then the pointer is advanced by <skip_images> times the number of elements in one 2-dimensional image. Then <depth> 2-dimensional images are read, each having a subimage extracted in the manner described in Appendix A of the GLX Protocol Specification.

Dependencies on EXT_abgr

If EXT_abgr is supported, the <format> parameter of TexImage3DEXT accepts ABGR_EXT. Otherwise it does not.

Dependencies on EXT_texture

EXT_texture is required. All of the <components> tokens defined by EXT_texture are accepted by the <internalformat> parameter of TexImage3DEXT, with the same semantics that are defined by EXT_texture.

The query and error extensions defined by EXT_texture are extended in this document.

Errors

INVALID_ENUM is generated if <target> is not TEXTURE_3D_EXT or PROXY_TEXTURE_3D_EXT.

INVALID_ENUM is generated if the <target> parameter to GetTexParameteriv, GetTexParameterfv or GetTexImage is PROXY_TEXTURE_3D_EXT.

INVALID_VALUE is generated if <level> is less than zero

INVALID_ENUM is generated if <internalformat> is not ALPHA, RGB, RGBA, LUMINANCE, LUMINANCE_ALPHA, or one of the tokens defined by the EXT_texture extension. (Values 1, 2, 3, and 4 are not accepted as internal formats by TexImage3DEXT).

INVALID_VALUE is generated if <width>, <height>, or <depth> is less than zero, or cannot be represented as 2**k + 2*border for some integer k.

INVALID_VALUE is generated if <border> is not 0 or 1.

INVALID_ENUM is generated if <format> is not COLOR_INDEX, RED, GREEN, BLUE, ALPHA, RGB, RGBA, LUMINANCE, or LUMINANCE_ALPHA (or ABGR_EXT if EXT_abgr is supported).

INVALID_ENUM is generated if <type> is not UNSIGNED_BYTE, BYTE, UNSIGNED_SHORT, SHORT, UNSIGNED_INT, INT, or FLOAT.

INVALID_OPERATION is generated if TexImage3DEXT is called between execution of Begin and the corresponding execution of End.

TEXTURE_TOO_LARGE_EXT is generated if the texture as specified cannot be accommodated by the implementation. This error will not occur if none of <width>, <height>, or <depth> is greater than MAX_3D_TEXTURE_SIZE_EXT.

New State

Get Value	Get Command	Type	Initial Value	Attribute
UNPACK_SKIP_IMAGES_EXT	GetIntegerv	Z+	0	-

Dependencies

    This extension is written against the OpenGL 2.0 specification and version
    1.10.59 of the OpenGL Shading Language specification.

    This extension is interacts with EXT_framebuffer_object.

    This extension interacts with NV_geometry_program4.

    This extension interacts with NV_gpu_program4 or the OpenGL Shading
    Language, which provide the mechanisms necessary to access array textures.

    This extension interacts with EXT_texture_compression_s3tc and
    NV_texture_compression_vtc.

Overview

    This extension introduces the notion of one- and two-dimensional array
    textures. An array texture is a collection of one- and two-dimensional
    images of identical size and format, arranged in layers. A
    one-dimensional array texture is specified using TexImage2D; a
    two-dimensional array texture is specified using TexImage3D. The height
    (1D array) or depth (2D array) specify the number of layers in the image.

    An array texture is accessed as a single unit in a programmable shader,
    using a single coordinate vector. A single layer is selected, and that
    layer is then accessed as though it were a one- or two-dimensional
    texture. The layer used is specified using the "t" or "r" texture
    coordinate for 1D and 2D array textures, respectively. The layer
    coordinate is provided as an unnormalized floating-point value in the
    range [0,<n>-1], where <n> is the number of layers in the array texture.
    Texture lookups do not filter between layers, though such filtering can be

achieved using programmable shaders. When mipmapping is used, each level of an array texture has the same number of layers as the base level; the number of layers is not reduced as the image size decreases.

Array textures can be rendered to by binding them to a framebuffer object (EXT_framebuffer_object). A single layer of an array texture can be bound using normal framebuffer object mechanisms, or an entire array texture can be bound and rendered to using the layered rendering mechanisms provided by NV_geometry_program4.

This extension does not provide for the use of array textures with fixed-function fragment processing. Such support could be added by providing an additional extension allowing applications to pass the new target enumerants (TEXTURE_1D_ARRAY_EXT and TEXTURE_2D_ARRAY_EXT) to Enable and Disable.

New Procedures and Functions

```
void FramebufferTextureLayerEXT(enum target, enum attachment,
                                uint texture, int level, int layer);
```

New Tokens

Accepted by the <target> parameter of TexParameteri, TexParameteriv, TexParameterf, TexParameterfv, and BindTexture:

```
TEXTURE_1D_ARRAY_EXT                            0x8C18
TEXTURE_2D_ARRAY_EXT                            0x8C1A
```

Accepted by the <target> parameter of TexImage3D, TexSubImage3D, CopyTexSubImage3D, CompressedTexImage3D, and CompressedTexSubImage3D:

```
TEXTURE_2D_ARRAY_EXT
PROXY_TEXTURE_2D_ARRAY_EXT                      0x8C1B
```

Accepted by the <target> parameter of TexImage2D, TexSubImage2D, CopyTexImage2D, CopyTexSubImage2D, CompressedTexImage2D, and CompressedTexSubImage2D:

```
TEXTURE_1D_ARRAY_EXT
PROXY_TEXTURE_1D_ARRAY_EXT                      0x8C19
```

Accepted by the <pname> parameter of GetBooleanv, GetDoublev, GetIntegerv and GetFloatv:

```
TEXTURE_BINDING_1D_ARRAY_EXT                    0x8C1C
TEXTURE_BINDING_2D_ARRAY_EXT                    0x8C1D
MAX_ARRAY_TEXTURE_LAYERS_EXT                    0x88FF
```

```
    Accepted by the <param> parameter of TexParameterf, TexParameteri,
    TexParameterfv, and TexParameteriv when the <pname> parameter is
    TEXTURE_COMPARE_MODE_ARB:

        COMPARE_REF_DEPTH_TO_TEXTURE_EXT                0x884E

    (Note:  COMPARE_REF_DEPTH_TO_TEXTURE_EXT is simply an alias for the
    existing COMPARE_R_TO_TEXTURE token in OpenGL 2.0; the alternate name
    reflects the fact that the R coordinate is not always used.)

    Accepted by the <internalformat> parameter of TexImage3D and
    CompressedTexImage3D, and by the <format> parameter of
    CompressedTexSubImage3D:

        COMPRESSED_RGB_S3TC_DXT1_EXT
        COMPRESSED_RGBA_S3TC_DXT1_EXT
        COMPRESSED_RGBA_S3TC_DXT3_EXT
        COMPRESSED_RGBA_S3TC_DXT5_EXT

    Accepted by the <pname> parameter of
    GetFramebufferAttachmentParameterivEXT:

        FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER_EXT          0x8CD4

    (Note:  FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER is simply an alias for the
    FRAMEBUFFER_ATTACHMENT_TEXTURE_3D_ZOFFSET_EXT token provided in
    EXT_framebuffer_object.  This extension generalizes the notion of
    "<zoffset>" to include layers of an array texture.)

    Returned by the <type> parameter of GetActiveUniform:

        SAMPLER_1D_ARRAY_EXT                             0x8DC0
        SAMPLER_2D_ARRAY_EXT                             0x8DC1
        SAMPLER_1D_ARRAY_SHADOW_EXT                      0x8DC3
        SAMPLER_2D_ARRAY_SHADOW_EXT                      0x8DC4
```

Additions to Chapter 2 of the OpenGL 2.0 Specification (OpenGL Operation)

Modify section 2.15.3, "Shader Variables", page 75

```
    Add the following new return types to the description of GetActiveUniform
    on p. 81.

      SAMPLER_1D_ARRAY_EXT,
      SAMPLER_2D_ARRAY_EXT,
      SAMPLER_1D_ARRAY_SHADOW_EXT,
      SAMPLER_2D_ARRAY_SHADOW_EXT
```

Modify Section 2.15.4, Shader Execution (p. 84)

```
    (modify first paragraph, p. 86 -- two simple edits:

      (1) Change reference to the "r" coordinate to simply indicate that the
          reference value for shadow mapping is provided in the lookup
          function.  It's still usually in the "r" coordinate, except for
          two-dimensional array textures, where it's in "q".
```

(2) Add new EXT_gpu_shader4 sampler types used for array textures.)

Texture lookups involving textures with depth component data can either return the depth data directly or return the results of a comparison with a reference depth value specified in the coordinates passed to the texture lookup function, as described in section 3.8.14. The comparison operation is requested in the shader by using the shadow sampler types (sampler1DShadow, sampler2DShadow, sampler1DArrayShadow, or sampler2DArrayShadow) and in the texture using the TEXTURE_COMPARE_MODE parameter. ...

Additions to Chapter 3 of the OpenGL 2.0 Specification (Rasterization)

Modify Section 3.8, Texturing (p. 149).

(add new paragraph at the top of p. 150) Six types of texture are supported; each is a collection of images built from one-, two-, or three-dimensional array of image elements referred to as texels. One-, two-, and three-dimensional textures consist of a one-, two-, or three-dimensional texel arrays. One- and two-dimensional array textures are arrays of one- or two-dimensional images, consisting of one or more layers. Finally, a cube map is a special two-dimensional array texture with six layers that represent the faces of a cube. When accessing a cube map, the texture coordinates are projected onto one of the six faces.

Modify Section 3.8.1, Texture Image Specification (p. 150).

(modify first paragraph of section, p. 150) The command

```
  void TexImage3D( enum target, int level, int internalformat,
                   sizei width, sizei height, sizei depth, int border,
                   enum format, enum type, void *data );
```

is used to specify a three-dimensional texture image. target must be one of TEXTURE_3D for a three-dimensional texture or TEXTURE_2D_ARRAY_EXT for an two-dimensional array texture. Additionally, target may be either PROXY_TEXTURE_3D for a three-dimensional proxy texture, or PROXY_TEXTURE_2D_ARRAY_EXT for a two-dimensional proxy array texture. ...

(modify the fourth paragraph on p. 151) Textures with a base internal format of DEPTH_COMPONENT are supported by texture image specification commands only if target is TEXTURE_1D, TEXTURE_2D, TEXTURE_1D_ARRAY_EXT, TEXTURE_2D_ARRAY_EXT, PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_1D_ARRAY_EXT, or PROXY_TEXTURE_2D_ARRAY_EXT. Using this format in conjunction with any other target will result in an INVALID OPERATION error.

(modify the first paragraph on p. 153 -- In particular, add new terms w_b, h_b, and d_b to represent border width, height, or depth, instead of a single border size term b_s. Subsequent equations referring to b_s should be modified to refer to w_b, h_b, and d_b, as appropriate.)

```
... Counting from zero, each resulting Nth texel is assigned internal
integer coordinates (i, j, k), where

  i = (N mod width) - w_b
  j = (floor(N/width) mod height) - h_b
  k = (floor(N/(width*height)) mod depth) - d_b

and w_b, h_b, and d_b are the specified border width, height, and depth.
w_b and h_b are the specified <border> value; d_b is the specified
<border> value if <target> is TEXTURE_3D or zero if <target> is
TEXTURE_2D_ARRAY_EXT. ...

(modify equations 3.15-3.17 and third paragraph of p. 155)

  w_s = w_t + 2 * w_b                     (3.15)
  h_s = h_t + 2 * h_b                     (3.16)
  d_s = d_t + 2 * d_b                     (3.17)

... If <border> is less than zero, or greater than b_t, then the error
INVALID_VALUE is generated.

(modify the last paragraph on p. 155 on to p. 156)

The maximum allowable width, height, or depth of a texel array for a
three-dimensional texture is an implementation dependent function of the
level-of-detail and internal format of the resulting image array.  It must
be at least 2^(k-lod) + 2 * b_t for image arrays of level-of-detail 0
through k, where k is the log base 2 of MAX_3D_TEXTURE_SIZE, lod is the
level-of-detail of the image array, and b_t is the maximum border width.
It may be zero for image arrays of any level-of-detail greater than k. The
error INVALID VALUE is generated if the specified image is too large to be
stored under any conditions.

In a similar fashion, the maximum allowable width of a texel array for a
one- or two-dimensional, or one- or two-dimensional array texture, and the
maximum allowable height of a two-dimensional or two-dimensional array
texture, must be at least 2^(k-lod) + 2 * b_t for image arrays of level 0
through k, where k is the log base 2 of MAX_TEXTURE_SIZE. The maximum
allowable width and height of a cube map texture must be the same, and
must be at least 2^(k-lod) + 2 * b_t for image arrays level 0 through k,
where k is the log base 2 of MAX_CUBE_MAP_TEXTURE_SIZE.  The maximum
number of layers for one- and two-dimensional array textures (height or
depth, respectively) must be at least MAX_ARRAY_TEXTURE_LAYERS_EXT for all
levels.

(modify the fourth paragraph on p. 156) The command

  void TexImage2D( enum target, int level,
                   int internalformat, sizei width, sizei height,
                   int border, enum format, enum type, void *data );

is used to specify a two-dimensional texture image. target must be one of
TEXTURE_2D for a two-dimensional texture, TEXTURE_1D_ARRAY_EXT for a
one-dimensional array texture, or one of TEXTURE_CUBE_MAP_POSITIVE_X,
TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y,
TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, or
TEXTURE_CUBE_MAP_NEGATIVE_Z for a cube map texture. Additionally, target
```

may be either PROXY_TEXTURE_2D for a two-dimensional proxy texture, PROXY_TEXTURE_1D_ARRAY_EXT for a one-dimensional proxy array texture, or PROXY TEXTURE_CUBE_MAP for a cube map proxy texture in the special case discussed in section 3.8.11. The other parameters match the corresponding parameters of TexImage3D.

For the purposes of decoding the texture image, TexImage2D is equivalent to calling TexImage3D with corresponding arguments and depth of 1, except that

* The border depth, d_b, is zero, and the depth of the image is always 1 regardless of the value of border.

* The border height, h_b, is zero if <target> is TEXTURE_1D_ARRAY_EXT, and <border> otherwise.

* Convolution will be performed on the image (possibly changing its width and height) if SEPARABLE 2D or CONVOLUTION 2D is enabled.

* UNPACK SKIP IMAGES is ignored.

(modify the fourth paragraph on p. 157) For the purposes of decoding the texture image, TexImage1D is equivalent to calling TexImage2D with corresponding arguments and height of 1, except that

* The border height and depth (h_b and d_b) are always zero, regardless of the value of <border>.

* Convolution will be performed on the image (possibly changing its width) only if CONVOLUTION 1D is enabled.

(modify the last paragraph on p. 157 and the first paragraph of p. 158 -- changing the phrase "texture array" to "texel array" to avoid confusion with array textures. All subsequent references to "texture array" in the specification should also be changed to "texel array".)

We shall refer to the (possibly border augmented) decoded image as the texel array. A three-dimensional texel array has width, height, and depth ws, hs, and ds as defined respectively in equations 3.15, 3.16, and 3.17. A two-dimensional texel array has depth ds = 1, with height hs and width ws as above, and a one-dimensional texel array has depth ds = 1, height hs = 1, and width ws as above.

An element (i,j,k) of the texel array is called a texel (for a two-dimensional texture or one-dimensional array texture, k is irrelevant; for a one-dimensional texture, j and k are both irrelevant). The texture value used in texturing a fragment is determined by that fragment’s associated (s,t,r) coordinates, but may not correspond to any actual texel. See figure 3.10.

Modify Section 3.8.2, Alternate Texture Image Specification Commands (p. 159)

(modify second paragraph, p. 159 -- allow 1D array textures) The command

```
  void CopyTexImage2D( enum target, int level,
                       enum internalformat, int x, int y, sizei width,
                       sizei height, int border );
```

defines a two-dimensional texture image in exactly the manner of TexImage2D, except that the image data are taken from the framebuffer rather than from client memory. Currently, target must be one of TEXTURE_2D, TEXTURE_1D_ARRAY_EXT, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, or TEXTURE_CUBE_MAP_NEGATIVE_Z.

(modify last paragraph, p. 160) ... Currently the target arguments of TexSubImage1D and CopyTexSubImage1D must be TEXTURE_1D, the target arguments of TexSubImage2D and CopyTexSubImage2D must be one of TEXTURE_2D, TEXTURE_1D_ARRAY_EXT, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, or TEXTURE_CUBE_MAP_NEGATIVE_Z, and the target arguments of TexSubImage3D and CopyTexSubImage3D must be TEXTURE_3D or TEXTURE_2D_ARRAY_EXT. ...

(modify last paragraph, p. 161 and subsequent inequalities)

Negative values of xoffset, yoffset, and zoffset correspond to the coordinates of border texels, addressed as in figure 3.10. Taking w_s, h_s, d_s, w_b, h_b, and d_b to be the specified width, height, depth, and border width, height, and depth of the texture array, and taking x, y, z, w, h, and d to be the xoffset, yoffset, zoffset, width, height, and depth argument values, any of the following relationships generates the error INVALID VALUE:

```
    x < -w_b
    x + w > w_s - w_b
    y < -h_b
    y + h > h_s - h_b
    z < -d_b
    z + d > d_s - d_b
```

Modify Section 3.8.4, Texture Parameters (p. 166)

(modify first paragraph of section, p. 166) Various parameters control how the texel array is treated when specified or changed, and when applied to a fragment. Each parameter is set by calling

```
  void TexParameter{if}( enum target, enum pname, T param );
  void TexParameter{if}v( enum target, enum pname, T params );
```

target is the target, either TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, TEXTURE_CUBE_MAP, TEXTURE_1D_ARRAY_EXT, or TEXTURE_2D_ARRAY_EXT.

Modify Section 3.8.8, Texture Minification (p. 170)

(modify first paragraph, p. 172) ... For a one-dimensional or one-dimensional array texture, define v(x, y) == 0 and w(x, y) == 0; for a two-dimensional, two-dimensional array, or cube map texture, define w(x, y) == 0. ...

(modify second paragraph, p. 173) For one-dimensional or one-dimensional array textures, j and k are irrelevant; the texel at location i becomes the texture value. For two-dimensional, two-dimensional array, or cube map textures, k is irrelevant; the texel at location (i, j) becomes the texture value. For one- and two-dimensional array textures, the texel is obtained from image layer l, where

```
  l = clamp(floor(t + 0.5), 0, h_t-1), for one-dimensional array textures,
      clamp(floor(r + 0.5), 0, d_t-1), for two-dimensional array textures.
```

(modify third paragraph, p. 174) For a two-dimensional, two-dimensional array, or cube map texture,

```
  tau = ...
```

where tau_ij is the texel at location (i, j) in the two-dimensional texture image. For two-dimensional array textures, all texels are obtained from layer l, where

```
  l = clamp(floor(r + 0.5), 0, d_t-1).
```

And for a one-dimensional or one-dimensional array texture,

```
  tau = ...
```

where tau_i is the texel at location i in the one-dimensional texture. For one-dimensional array textures, both texels are obtained from layer l, where

```
  l = clamp(floor(t + 0.5), 0, h_t-1).
```

(modify first two paragraphs of "Mipmapping", p. 175) TEXTURE_MIN_FILTER values NEAREST_MIPMAP_NEAREST, NEAREST_MIPMAP_LINEAR, LINEAR_MIPMAP_NEAREST, and LINEAR_MIPMAP_LINEAR each require the use of a mipmap. A mipmap is an ordered set of arrays representing the same image; each array has a resolution lower than the previous one.

If the image array of level level_base, excluding its border, has dimensions, w_t × h_t × d_t, then there are floor(log2(maxsize)) + 1 levels in the mipmap, where

```
  maxsize = w_t,                  for one-dimensional and one-dimensional
                                  array textures,
            max(w_t, h_t),        for two-dimensional, two-dimensional
                                  array, and cube map textures
            max(w_t, h_t, d_t),   for three dimensional textures.
```

Numbering the levels such that level level_base is the 0th level, the ith array has dimensions

```
  max(1, floor(w_t/w_d)) x max(1, floor(h_t/h_d)) x max(1, floor(d_t/d_d))
```

where

```
  w_d = 2 ^ i;
  h_d = 1, for one-dimensional array textures and
        2 ^ i, otherwise; and
  d_d = 1, for two-dimensional array textures and
        2 ^ i, otherwise,
```

until the last array is reached with dimension 1 × 1 × 1.

Each array in a mipmap is defined using TexImage3D, TexImage2D, CopyTexImage2D, TexImage1D, or CopyTexImage1D; the array being set is indicated with the level-of-detail argument level. Level-of-detail numbers proceed from level_base for the original texture array through p = floor(log2(maxsize)) + level_base with each unit increase indicating an array of half the dimensions of the previous one (rounded down to the next integer if fractional) as already described. All arrays from level_base through q = min{p, level_max} must be defined, as discussed in section 3.8.10.

(modify third paragraph in the "Mipmap Generation" section, p. 176)

The contents of the derived arrays are computed by repeated, filtered reduction of the level_base array. For one- and two-dimensional array textures, each layer is filtered independently. ...

Modify Section 3.8.10, Texture Completeness (p. 177)
