MIPS Implementation

Material from Chapter 3 of H&P (for DLX).
Material from Chapter 6 of P&H (for MIPS).

Outline: (In this set.)
- Unpipelined DLX Implementation. (Diagram only.)
- Pipelined DLX and MIPS Implementations: Hardware, notation, hazards.
- Dependency Definitions.
- Data Hazards: Definitions, stalling, bypassing.
- Control Hazards: Squashing, one-cycle implementation.

Outline: (Covered in class but not yet in set.)
- Operation of nonpipelined implementation, elegance and power of pipelined implementation.
- Computation of CPI for program executing a loop.

Unpipelined Implementation

Diagram of the DLX datapath showing the pipeline stages:

IF: Instruction Fetch
ID: Instruction Decode and Register Fetch
EX: Execute
MEM: Memory Access
WB: Write Back

Note: diagram omits connections for some instructions.

Pipelined DLX Implementation

Diagram of the pipelined DLX implementation showing the pipeline stages.

Note: diagram omits connections for some instructions.

Pipelined MIPS Implementation

Diagram of the pipelined MIPS implementation showing the pipeline stages.

Note: diagram omits connections for some instructions.
**Pipeline Details**

**Pipeline Segments** a.k.a. **Pipeline Stages**

Divide pipeline into *segments*.

Each segment occupied by at most one instruction.

At any time, different segments can be occupied by different instructions.

Segments given names: IF, ID, EX, MEM, WB

Sometimes MEM shortened to ME.

**Pipeline Registers** a.k.a. **Pipeline Latches**

Registers separating pipeline segments.

Written at end of each cycle.

To emphasize role, drawn as part of dividing bars.

Registers named using pair of segment names and register name.

For example, IF/ID.IR, ID/EX.IR, ID/EX.A (used in text, notes).

if_id_ir, id_ex_ir, id_ex_rs_val (used in Verilog code).

---

**Pipeline Execution Diagram**

Diagram showing the pipeline segments that instructions occupy as they execute.

Time on horizontal axis, instructions on vertical axis.

Diagram shows where instruction is at a particular time.

<table>
<thead>
<tr>
<th>Cycle</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>add r1, r2, r3</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>and r4, r5, r6</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>lw r7, 8(r9)</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A vertical slice (*e.g.*, at cycle 3) shows processor activity at that time.

In such a slice a **segment should appear at most once** ...

... if it appears more than once execution not correct ...

... since a segment can only execute one instruction at a time.

---

**Instruction Decoding and Pipeline Control**

**Pipeline Control**

Setting control inputs to devices including ...

... multiplexor inputs ...

... function for ALU ...

... operation for memory ...

... whether to clock each register ...

... *et cetera*.
Options for controlling pipeline:

- Decode in ID
  Determine settings in ID, pass settings along in pipeline latches.

- Decode in Each Stage
  Pass opcode portions of instruction along.
  Decoding performed as needed.

Real systems decode in ID.

For clarity, diagrams misleadingly imply decoding in stage needed ... ... by passing entire instruction along.

Example given later in this set.

Dependencies and Hazards

Incorrect execution due to...
... dependencies in program...
... and hazards in hardware (pipeline).

Incorrect execution above is the “fault” of the hardware... because the ISA does not forbid dependencies.

Dependency:
A relationship between two instructions...
... indicating that their execution should be (or appear to be) in program order.

Hazard:
A potential execution problem in an implementation due to overlapping instruction execution.

There are several kinds of dependencies and hazards.

For each kind of dependence there is a corresponding kind of hazard.

Dependencies

Dependency:
A relationship between two instructions...
... indicating that their execution should be (or appear to be) in program order.

If there is a dependency between instruction A and instruction B...
... and B follows A in program order...
... then B is said to be dependent on A.

If B is dependent on A then A should appear to execute before B.

Dependency Types:

- True, Data, or Flow Dependence (Three different terms used for the same concept.)
- Name Dependence
- Control Dependence
**Data Dependence**

Data Dependence: (a.k.a., **True** and **Flow Dependence**)
A dependence between two instructions...
... indicating data needed by the second is produced by the first.

Example:

```plaintext
add r1, r2, r3
sub r4, r1, r5
and r6, r4, r7
```

The `sub` is dependent on `add` (via `r1`).
The `and` is dependent on `sub` (via `r4`).
The `and` is dependent `add` (via `sub`).

Execution may be incorrect if...
... a program having a data dependence...
... is run on a processor having an uncorrected RAW hazard.

---

**Name Dependencies**

There are two kinds: **antidependence** and **output dependence**.

**Antidependence:**
A dependence between two instructions...
... indicating a value written by the second...
... that the first instruction reads.

Antidependence Example

```plaintext
add r1, r2, r3
sub r2, r4, r5
```

`sub` is antidependent on the `add`.
Execution may be incorrect if...
... a program having an antidependence...
... is run on a processor having an uncorrected WAR hazard.

---

**Control Dependence:**
A dependence between a branch instruction and a second instruction...
... indicating that whether the second instruction executes...
... depends on the outcome of the branch.

Control Dependence Example

```plaintext
beq $1, $0 SKIP # Delayed branch
nop
add $2, $3, $4
SKIP:
sub $5, $6, $7
```

The `add` is control dependent on the `beq`.
The `sub` is not control dependent on the `beq`.
Pipeline Hazards

**Hazard:**
A potential execution problem in an implementation due to overlapping instruction execution.

**Interlock:**
Hardware that avoids hazards by stalling certain instructions when necessary.

**Hazard Types:**
- **Structural Hazard:**
  Needed resource currently busy.
- **Data Hazard:**
  Needed value not yet available or overwritten.
- **Control Hazard:**
  Needed instruction not yet available or wrong instruction executing.

Data Hazards

Identified by acronym indicating correct operation.
- **RAW:** Read after write, akin to data dependency.
- **WAR:** Write after read, akin to anti dependency.
- **WAW:** Write after write, akin to output dependency.

DLX and MIPS implementations above only subject to RAW hazards.
RAR not a hazard since read order irrelevant (without an intervening write).

Interlocks

When threatened by a hazard:
- **Stall** (Pause a part of the pipeline.)
  Stalling avoids overlap that would cause error.
  This does slow things down.

- Add hardware to avoid the hazards.
  Details of hardware depend on hazard and pipeline.
  Several will be covered.

Structural Hazards

Cause: two instructions simultaneously need one resource.

Solutions:
- Stall.
  Duplicate resource.

Pipelines in this section **do not** have structural hazards.
Covered in more detail with floating-point instructions.
Data Hazards

HP Chapter-3 DLX and MIPS Subject to RAW Hazards.

Consider the following incorrect execution of code containing data dependencies.

<table>
<thead>
<tr>
<th>Cycle</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>add r1, r2, r3</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>sub r4, r1, r5</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>and r6, r1, r8</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>xor r9, r4, r11</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Execution incorrect because...
- sub reads r1 before add writes (or even finishes computing) r1...
- and reads r1 before add writes r1, and...
- xor reads r4 before sub writes r4.

Problem fixed by stalling the pipeline.

Stall

To pause execution in a pipeline from IF up to a certain stage.

With stalls, code can execute correctly:

<table>
<thead>
<tr>
<th>Cycle</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>add r1, r2, r3</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>sub r4, r1, r5</td>
<td>IF</td>
<td>ID</td>
<td>----&gt;</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>and r6, r1, r8</td>
<td>IF</td>
<td>----&gt;</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>xor r9, r4, r11</td>
<td>IF</td>
<td>ID</td>
<td>-&gt;</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Arrow shows that instructions stalled.
Stall creates a bubble, segments without valid instructions, in the pipeline.
With bubbles present, CPI is greater than its ideal value of 1.

Bypassing

Some stalls are avoidable.

Consider again:

<table>
<thead>
<tr>
<th>Cycle</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>add r1, r2, r3</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>sub r4, r1, r5</td>
<td>IF</td>
<td>ID</td>
<td>----&gt;</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>and r6, r1, r8</td>
<td>IF</td>
<td>----&gt;</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>xor r9, r4, r11</td>
<td>IF</td>
<td>ID</td>
<td>-&gt;</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note that the new value of r1 needed by sub...
...has been computed at the end of cycle 2...
...and isn’t really needed until the beginning of the next cycle, 3.

Execution was incorrect because the value had to go around the pipeline to ID.
Why not provide a shortcut?
Why not call a shortcut a bypass or forwarding path?
Non-Bypassed MIPS

Bypassed MIPS

MIPS Implementation With Some Forwarding Paths:

Not all stalls are avoidable.

Stall due to `lw` could not be avoided (data not available in cycle 3).

Stall in cycles 5 and 6 could be avoided with a new forwarding path.

It works!
Bypass Control Logic for Lower ALU Mux

Start with logic for rd, show path of Mux logic.

Control logic not minimized (for clarity).

Control Logic Generating ID/EX.RD.

Present in previous implementations, just not shown.

Determines which register gets written based on instruction.

Instruction categories used in boxes such as

- **Load** (some instructions omitted):
  - Non-link CTI: branches and jumps except linking jumps (jal and jalr).
  - Store: All store instructions.
  - Type I ALU: All Type I ALU instructions.
  - Load: All load instructions.
  - Type R: All Type R instructions.
  - Link CTI: jal and jalr.
Bypass Control Logic, Continued

Logic Generating *ID/EX_MUX*.

Box determines if two register numbers are equal.

Register number zero is not equal register zero, nor any other register. (The bypassed zero value might not be zero.)

Control Hazards

Cause: on taken CTI several wrong instructions fetched.

Consider:

![Diagram of control hazards](image)

Handling Instructions Following a Taken Branch Delay Slot

Option 1: Don’t fetch them.

Possible (with pipelining) because ...

... fetch starts (sw in cycle 2) ...

... after branch decoded.

(Would be impossible ... for non-delayed branch.)

Example of *incorrect execution*

<table>
<thead>
<tr>
<th>I Addr</th>
<th>Cycle</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x100</td>
<td>bgtz</td>
<td>r4,</td>
<td>TARGET</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x104</td>
<td>sub</td>
<td>r4,</td>
<td>r2,</td>
<td>r5</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
</tr>
<tr>
<td>0x108</td>
<td>sw</td>
<td>0(r2),</td>
<td>r1</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x110</td>
<td>or</td>
<td>r6,</td>
<td>r1,</td>
<td>r8</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
</tr>
<tr>
<td>0x111</td>
<td>or</td>
<td>r12,</td>
<td>r13,</td>
<td>r14</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>TARGET: ! TARGET = 0x200</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x200</td>
<td>xor</td>
<td>r9,</td>
<td>r4,</td>
<td>r11</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
</tr>
</tbody>
</table>

Branch is taken yet two instructions past delay slot (sub) complete execution.

Branch target finally fetched in cycle 4.

Problem: Two instructions following delay slot.
Handling Instructions Following a Taken Branch

Option 2: Fetch them, but squash (stop) them in a later stage.

This will work if instructions squashed . . .

. . . before modifying architecturally visible storage (registers and memory).

Memory modified in MEM stage and registers modified in WB stage . . .

. . . so instructions must be stopped before beginning of MEM stage.

Can we do it? Depends depends where branch instruction is.

In example, need to squash sw before cycle 5.

During cycle 3 bgtz in MEM . . .

. . . it has been decoded and the branch condition is available . . .

. . . so we know whether the branch is taken . . .

. . . so sw can easily be squashed before cycle 5.

Option 2 will be used.

Instruction Squashing

In-Flight Instruction::
An instruction in the execution pipeline.

Later in the semester a more specific definition will be used.

Squashing:: [an instruction]
preventing an in-flight instruction . . .

. . . from writing registers, memory or any other visible storage.

Squashing also called: nulling, abandoning, and cancelling..

Like an insect, a squashed instruction is still there (in most cases) but can do no harm.

Squashing Instruction in Example DLX Implementation

Two ways to squash.

• Prevent it from writing architecturally visible storage.

Replace destination register control bits with zero. (Writing zero doesn’t change anything.)

Set memory control bits (not shown so far) for no operation.

• Change Operation to nop.

Would require changing many control bits.

Squashing shown that way here for brevity.

Illustrated by placing a nop in IR.

Why not replace squashed instructions with target instructions?

Because there is no straightforward and inexpensive way . . .

. . . to get the instructions where and when they are needed.

(Curvy sideways and expensive techniques covered in Chapter 4.)
Example of correct execution

<table>
<thead>
<tr>
<th>I Addr</th>
<th>Cycle</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x100</td>
<td>bgtz</td>
<td>r4, TARGET</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x104</td>
<td>sub</td>
<td>r4, r2, r5</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x108</td>
<td>sw</td>
<td>0(r2), r1</td>
<td>IF</td>
<td>IDx</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x10c</td>
<td>and</td>
<td>r6, r1, r8</td>
<td>IFx</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x110</td>
<td>or</td>
<td>r12, r13, r14</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

TARGET: ! TARGET = 0x200
0x200 xor r9, r4, r11 | IF | ID | EX | MEM | WB |

Branch outcome known at end of cycle 2 ...
... wait for cycle 3 when doomed instructions (sw and and) in flight ...
... and squash them so in cycle 4 they act like nops.

Two cycles (1, 2, and 3), are lost.

Two cycles called a branch penalty.

Two cycles is alot of cycles, is there something we can do?

Zero-Cycle Branch Delay Implementation

Compute branch target and condition in ID stage.

Workable because register values not needed to compute branch address and ...
... branch condition can be computed quickly.

Now how fast will code run?

<table>
<thead>
<tr>
<th>I Addr</th>
<th>Cycle</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x100</td>
<td>bgtz</td>
<td>r4, TARGET</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x104</td>
<td>sub</td>
<td>r4, r2, r5</td>
<td>IF</td>
<td>ID</td>
<td>EX</td>
<td>MEM</td>
<td>WB</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x108</td>
<td>sw</td>
<td>0(r2), r1</td>
<td>IF</td>
<td>IDx</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x10c</td>
<td>and</td>
<td>r6, r1, r8</td>
<td>IFx</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x110</td>
<td>or</td>
<td>r12, r13, r14</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

TARGET: ! TARGET = 0x200
0x200 xor r9, r4, r11 | IF | ID | EX | MEM | WB |

No penalty, not a cycle wasted!!
